VOLUME VI
CASTE—CIVIL LAW

CASTE, *kāst*, one of many hereditary units in the social systems of India, Pakistan, and Ceylon. Membership in a caste can be obtained only through birth and cannot later be changed. Avoidance or denial of caste affiliation may be achieved by moving out of the region where one's caste exists, but by no other means. Social action may ostracize a person from his caste, but this does not free him to take up affiliation elsewhere. Despite agreement on these features of caste, the word is now used in two different ways.

In its more generalized sense, caste is coupled with class and refers to any group, the membership in which is determined by heredity, with a socially recognized advantage or disadvantage in status and privilege. Thus one caste is superior, or inferior, to another and individuals within it are consequently aided, or hampered, in their personal struggle for position, wealth, and social recognition. It is assumed when the word is used in this way that the persons in a society generally desire the same things. When the attainment of these goals is regularly helped or hindered by certain accidents of birth, castes develop and some individuals' opportunities for success are limited according to circumstances beyond their control. Caste is frequently regarded by people who use the word in this way as a symptom of enforced social inequality and as such is something to be eradicated or, at the very least, alleviated.

In its more precise meaning, caste refers to the social units within the highly complex social systems of India, Pakistan, and Ceylon. The caste system of these countries has existed for well over 2,000 years. It is in connection with this system that the Portuguese word *casta* attained its present wide application as English *caste*, and it is from this that the usage described above derived. The term used in the sense of a frozen class system is normative as well as descriptive, and reflects the powerful impression made by the actual caste system upon Western observers. As early as 1871, Sir Henry Maine wrote: "I am aware that the popular impression . . . is that Indian society is divided, so to speak, into a number of horizontal strata, each representing a caste. This is an entire mistake. . . . The true view of India is that, as a whole, it is divided into a vast number of independent, self-acting, organised social groups. . . ." (*Village Communities in the East and West*, pp. 56-57, London 1872). Since Sir Henry's day, caste as class has developed a literature and social theory of its own. The fact that

it did not offer an accurate view of Indian society was often neglected. Caste came to be used indiscriminately by Westerner and Indian alike to refer to an established social order and to a situation fostering social injustice. Many historical and sociological factors, particularly during the last several centuries, have, indeed, influenced caste in the subcontinent in the direction of class. Considering these changes, it is little wonder that the frame of reference has frequently been, and often still is, confused.

In contrast, the traditional view of caste is explicitly stated in treatises on Hindu law. The classic among these is the Code of Manu, generally dated between 200 B.C. and 100 A.D. but known to be founded on material of earlier date. In these and other sacred writings of Hinduism from the time of the Rig Veda (about 2000 B.C.) onward the word used to refer to caste is *varna* (Sanskrit *varṇa*). All of society is conceived as being composed of five interdependent divisions. The first four are the *varna*: (1) the Brahmins, or priests and scholars; (2) the Kshatriyas, or warriors and rulers; (3) the Vaisyas, or husbandmen, merchants, and artisans; and (4) the Sudras, or servants. The fifth division is composed of outcastes. According to the Hindu doctrine of rebirth, these are among the stages through which the soul passes. The first three *varna* are "twice born" because their members undergo an initiation ceremony not permitted to Sudras. They then wear the sacred thread as a sign of initiation, may study the Veda, and perform the sacraments. Sudras may be further distinguished as to whether or not they are "clean." It is important to note that the opposite of "clean" is not "dirty," but "unclean." Cleanliness in this sense refers to ritual only, and the unclean are those who are ritually polluting. Contact with them, whether direct or indirect, must be counteracted by ritual purification before the ordinary activities of life may be resumed. The *varna* are said to have originated from the deity: the Brahmin sprang from the mouth, the Kshatriya from the arms, the Vaisya from the thighs, and the Sudra from the feet.

Though this account of caste, recorded in Sanskrit literature, is recognizably tied to Hindu doctrine, it is, in a strict sense, more characteristic of Brahmanism, for there are important Hindu sects which are opposed to much of Brahmanic philosophy, especially as related to caste practice. Nevertheless, Brahmanism has had an extremely important influence. Groups which fall outside of its direct orbit, such as tribal

groups and members of other religious faiths, can be seen to bear its imprint. As some writers have pointed out, there has been a gradual Sanskritization of even non-Hindu peoples and a general dissemination of Brahman ethics in the subcontinent.

The hereditary units of the caste system are known as *jati* (Sanskrit *jāti*). They are many in number (between 2,000 and 3,000) and, according to Hindu doctrine, have arisen through the splitting of the *varna*. Whatever their origin, castes are present in all the major populations of the subcontinent. Throughout the period of historical Hinduism, there have been movements opposed to caste, such as Buddhism, Jainism, and Sikhism. The beliefs of Islam, which entered Sind as early as the 8th century, deny caste. And more recently, the attempts of followers of Gandhi to relieve the social position of the outcastes, or untouchables, have culminated in the absolute prohibition of untouchability in the Constitution of the Republic of India. Nevertheless, castes as social units have existed within groups denying the caste philosophy.

Despite their actual number, castes in any one locality are arranged in hierarchical order. Each person knows the relative position of his caste. Although certain positions may be in doubt at any one time, with a few castes claiming greater recognition and others accepting degradation, no caste is so low that it cannot refer to another below it in the hierarchy. One of the Brahman castes is generally at the top, but in some regions another, often a militaristic group, may claim ascendancy. Moslems (Muslims) may constitute a single caste in a dominantly Hindu population or, as in parts of Pakistan, Hindu and Moslem castes may interlace in the hierarchy. In the south of India, where caste regulations are exceptionally rigid, some castes are regarded as *Right Hand* and some as *Left Hand* castes. Not all castes in the south belong to these divisions, but the rivalries between them sometimes spread beyond them.

The lines between the castes are clearly demarcated by the rules of pollution. Most important among these are rules concerning the taking of food and water. Restrictions concerning *pakka* dishes, those cooked with ghee (clarified butter), are less severe than those for *kachcha* foods, which are cooked with water. Every caste knows those castes from which its members can accept food and those from which they cannot. If these rules are relaxed by the individual, it is always with the consciousness that he is doing so. Caste members may eat with each other, and marriages are also regularly arranged within the caste. Except in cases of hypergamy, where a bridegroom is sought from a higher-ranking caste, marriages are regularized within the caste. Each caste, however, contains *gotras*, or subcastes within which marriage would be regarded as incest. Marriage within caste must also be across *gotra*.

Castes regulate these matters themselves. They also have their own rituals, beliefs, and restrictions or privileges, concerning which no one has the right to dictate. Castes are thus largely autonomous, and they tend to be interdependent in practice since each has its own traditional areas of economic and social specialization. Caste names are often synonymous with the names of occupations such as washerman, goldsmith, barber, accountant, marriage go-between, vegetable

farmer, toddy tapper, or musician. Not all members of a caste need always follow its traditional specialization. But a consistent and recognized shift in either practice or specialization brings about a shift in caste definition and ranking. Such changes are still in many cases regulated by caste panchayats or councils. When caste panchayats were more powerful, they also always served as disciplinary bodies, intracaste disputes being handled by village or cross-caste councils.

Today, in the newly born nations of the subcontinent, caste regulations are subject to foreign—and potent—forces. Yet many aspects of the social order continue to encourage the formation, and the vitality, of hereditary, interdependent, and self-acting units within the greater whole of society. See also INDIA—*Anthropology and Sociology*, and *Religion and Philosophy*.

Bibliography.—For an example of the use of caste as class see Tumin, Melvin M., *Caste in a Peasant Society* (Princeton 1952). For a description of caste as social order see Hutton, John H., *Caste in India: Its Nature, Function and Origins* (Cambridge, Eng., 1952); and Ryan, Bryce, *Caste in Modern Ceylon* (New Brunswick, N. J., 1953). The last two contain extensive bibliographies.

MARIAN W. SMITH,
The London School of Economics and Political Science, University of London.

CASTEL GANDOLFO, kās-tēl' gān-dōl'fō, commune, Italy, in Roma Province, Latium; 13 miles southeast of Rome. It is famous as a summer resort of the popes. Built on the site of ancient Alba Longa supposedly founded by Ascanius, it is situated on the western edge of the Alban Hills, overlooking Albano Laziale, a crater lake. The area is rich in olive groves, orchards, and vineyards. During World War II the town was damaged in air raids.

The papal palace, in the Piazza del Plebiscito, was built in the 17th century on the ruins of an earlier castle and was designed by Carlo Maderno. Nearby, Villa Barberini, begun by Urban VIII, was built on the site of a villa belonging to the Roman emperor Domitian. Both the palace and the villa enjoy extraterritorial rights. Also in the Piazza del Plebiscito are the church of San Tommaso da Villanova (1661), which contains work of Giovanni Lorenzo Bernini, and a fountain executed by the same artist. The astronomical observatory, Specola Vaticana, was established in 1936. Pop. (1951) 4,212.

CASTEL SANT'ANGELO. See SAINT ANGELO CASTLE.

CASTELAR Y RIPOLL, kās-tā-lār' ē rē-pōl'y, Emilio, Spanish orator and statesman: b. Cadiz, Spain, Sept. 8, 1832; d. San Pedro del Piñatar, Murcia Province, May 25, 1899. He was professor of history and philosophy at the University of Madrid from 1856 to 1865 and, after a short exile, from 1868 to 1875. An active republican leader, he was foreign minister from September 1873 to January 1874 during the short-lived republic that followed the abdication of King Amadeus. Later during the reign of Alfonso XII he became a member of the Cortes. He had advocated a separation of the church and the state.

He published *La civilización en los cinco primeros siglos del Cristianismo* (1859), *Historia del movimiento republicano en Europa*, 2 vols. (1873-1874), *Historia del descubrimiento de América* (1892), *Discursos parlamentarios y*

políticos (1871-1873), and biographies of Lord Byron and Fra Filippo Lippi. However, he is principally remembered for his oratory: Castelar was the most renowned orator of 19th century Spain.

CASTELEIN, kās-tē-līn', **Matthijs de**, Flemish poet and critic: b. Pamele, near Audenaarde, Belgium, 1485; d. there, April 1550. A member of the Rederijkerskamers, or Chambers of Rhetoric, he was the acknowledged lawgiver for all Dutch grammarians; he set the pattern in his *Const van Rhetoryken* (completed 1548; published 1555), the first treatise on Flemish versification which also included some ballads and songs. He wrote over 100 plays, one of which was *Historie van Pyramus en Thisbe*.

CASTELFRANCO, **Giorgione da**. See **GIORGIONE**.

CASTELFRANCO DELL'EMILIA, kās-tēl-frāng'kō dēl-lā-mē'lyā, commune, Italy, in Moderna Province; about 7 miles southeast of Moderna. In 1628 Urban VIII erected, just outside the city on the Bologna frontier, a large fort which later became a prison. The town is the approximate site of the ancient Forum Galorum where Octavian defeated Mark Antony in 43 B.C. Milk products, wine, and paper are produced. Pop. (1951) 19,753.

CASTELFRANCO VENETO, kās-tēl-frāng'kō vā-nā-tō, commune, Italy, in Treviso Province; about 15 miles west of Treviso. The city is surrounded by medieval walls. Il Giorgione, who was born here, painted the altar-piece, "Madonna with St. Francis and St. Liberale," in the local cathedral. In 1805, near the Musone River crossing, the French defeated the Austrians. Manufactures include textiles, leather goods, pharmaceuticals, alcohol, and electrical equipment. Pop. (1951) 19,984.

CASTELLAMMARE DEL GOLFO, kās-tēl-lām-mā'rā dāl gōl'fō, seaport, Sicily, in Trapani Province; about 5 miles northwest of Alcamo. The port is located on a fertile coastal plain on the Gulf of Castellammare. It is a watering place and has small tuna fisheries. Pop. (1951) 18,740.

CASTELLAMMARE DI STABIA, kās-tēl-lām-mā'rā dē stā'byā, seaport, Italy, in the Province of Nāpoli; about 16 miles southeast of Naples, to which it is connected by railroad and highway; it extends for over a mile along the southeast end of the peninsula of Sorrento. Because of its beautiful location, its sea bathing facilities, and the variety of its mineral waters, used since Roman times, it is much visited by tourists. Vineyards and fruit and vegetable orchards cover its pleasant surroundings. The local shipyards, established by the Bourbons in 1783, are one of the oldest in Italy; after 1900 they were enlarged and modernized. Macaroni, cheese, alcohol, rope, canned goods, and olive oil are the chief products; fishing is also important. There is a 16th century cathedral, a municipal palace, and the restored remains of the 13th century castle of Frederick II. The Villa Quisisana, built on a height by the Angevins, is now a hotel and offers a gorgeous view of the bay. The town lies on the site of ancient Stabiae

which was destroyed by the eruption of Mount Vesuvius in 79 A.D.; near here Pliny met his death. In 1779 the French, under Jacques E.J.A. Macdonald, defeated the British and Neapolitans. Pop. (1951) 56,115.

CASTELLANA, kās-tāl-lā'nā, commune, Italy, in Bari Province; 16 miles southeast of Bari and about 7 miles from the Adriatic. It is located in the fertile Apulia plateau where olives and vines are grown; macaroni and textiles are manufactured. Pop. (1951) 13,850.

CASTELLANE, kās-tēl-lān, **COMTE Esprit Victor Elisabeth Boniface de**, French marshal: b. Paris, France, 1788; d. Lyon, 1862. He entered the army in 1804 and took part in most of Napoleon's campaigns. In 1815 he became a colonel of the hussars of the royal guard and following the siege of Antwerp (1832) was made lieutenant general. However, he opposed the revolution, lost his command, and consequently went over to Louis Napoleon for a short time. After his return, he was made commander of Lyon in 1850 and two years later became marshal of France. His *Journal* was published in 1897.

CASTELLANI, kās-tāl-lā'nē, **SIR Aldo**, Italian bacteriologist: b. Florence, Italy, Sept. 8, 1875. He studied at the universities of Florence and Bonn and at the London School for Tropical Medicine. Working in Uganda with two British physicians, Sir David Bruce and David Nunes Nabarro, he discovered in 1903 *Trypanosoma gambiense*, the organism causing sleeping sickness, and in 1907 described *Treponema pertenue* as the cause of yaws. In 1926 and 1932 he was professor of tropical medicine at Tulane and Louisiana State universities, respectively. He has published several books, among which is *A Manual of Tropical Medicine* (with Albert John Chalmers, 1910), and edited the *Journal of Tropical Medicine*. He developed Castellani's absorption test, and Castellani's disease, a bronchial spirochetosis, is named for him. In 1929 he was knighted in England and he has received numerous honors in Italy. During the Ethiopian campaign he was surgeon general for the Italian forces.

CASTELLESI, **Adriano**. See **ADRIAN OF CASTELLO**.

CASTELLI, kās-tēl'lē, **Benedetto**, Italian mathematician and physicist: b. Brescia, 1577; d. Rome, c.1644. He entered the Benedictine Order and was abbot at Monte Cassino. A pupil of Galileo, he became a successful professor of mathematics at the University of Pisa and at the Collegio della Sapienza, Rome. He distinguished himself in the field of hydraulics and was consulted by Urban VIII in his projects for the regulation of Italian rivers. Torricelli was one of his pupils. *Della misura delle acque correnti* (Rome 1628), his principal work, was translated into English in 1660 and into French in 1664.

CASTELLI, kās-tēl'ē, **Ignaz Franz**, Austrian dramatist: b. Vienne, Austria, March 6, 1781; d. there, Feb. 5, 1862. As a writer of patriotic songs, he gained considerable recognition with the publication of his *Kriegslied für die*

österreichische Armee. In 1811 he was appointed court poet to the Kärntner Theater in Vienna, but in 1815 went to Paris as secretary to Count Cavriani. Upon his return he resumed his former position.

He composed librettos for Joseph Weigl's *Die Schweizerfamilie* (1809) and Schubert's *Die Verschwornen* and adapted Meyerbeer's *Huguenots*. He founded *Allgemeiner musikalischer Anzeiger* and was its editor from 1829 to 1840. As a popular dramatist, his numerous plays were effective in their satirization of Viennese foibles. His last publication was *Memoiren meines Lebens*, 4 vols. (1861–1862).

CASTELLIO, kās-těl'i-ō, or **CASTALIO**, kās-tā'li-ō, **Sebastianus** (Fr. SÉBASTIEN CHÂTILLON, shā-tē'yōn, or CHÂTEILLON, shā-tā'yōn), French Protestant theologian and humanist: b. Saint-Martin-du-Fresne, Ain, France, 1515; d. Basel, Switzerland, Dec. 29, 1563. At the invitation of Calvin he settled in Geneva where he became rector of the college in 1541. But because of differences regarding questions of religious belief, especially his erotic interpretation of the Song of Solomon, he was banished and settled in Basel in 1545 where he spent the remainder of his life. In 1553 he became professor of Greek at the university, and the following year wrote, under the pseudonym of Martin Bellie, his famous condemnation of the execution of Servetus in both Latin and French, *De haereticis et Traité des hérétiques*. He made two remarkable translations of the Bible, one in Latin, the other in French.

CASTELLO, kās-těl'lō, **Giovanni Battista** (called IL BERGAMASCO, ēl bār-gā-mās'kō), Italian painter, sculptor, and architect: b. at or near Bergamo, Italy, c.1509; d. Madrid, Spain, 1569, although 1579 is sometimes quoted. He belonged to the school of Genoese painters, but apparently was unrelated to other artists of the same name. Invited to Madrid as architect of the royal palaces by Philip II, Castello assisted in the restoration of the Alcázar and the construction of the Escorial.

CASTELLON DE LA PLANA, kās-tā-[l]yōn' dā lā plā'nā, province, Spain, on the Mediterranean coast; 2,579 square miles. The northern and western mountainous regions slope down to the fertile coastal area, which is still irrigated by canals dating from Moorish times; the province is drained by short torrential rivers. Essentially an agricultural district, its products include grapes, olives, grain, fruits, and vegetables, especially oranges and rice; there are few minerals. Textiles, porcelain, cement, soap, and paper are the principal manufactures; sericulture and hemp processing are also carried on. El Grao de Castellón and Vinaroz are the two important ports. Pop. (1950) 325,091.

CASTELLON DE LA PLANA, city, Spain, capital of the province of the same name; 40 miles north-northeast of Valencia and 200 miles east-northeast of Madrid. It is located in a fertile irrigated plain, producing citrus fruit, olive oil, wine, cereals, and rice. Cement, sandals, and tiles are manufactured. The town is connected by railroad with its port, El Grao de Castellón, only three miles to the east; oranges, hemp, and tiles are exported. The present town

is entirely modern; the original town, now in ruins, occupied a hill to the north. James I of Aragon wrested it from the Moors in 1233. Later it suffered under the *comuneros*' rising in the 16th century and again in the 19th century during the Peninsular War. In 1938 it fell to the forces of Francisco Franco during the Spanish Civil War. Pop. (1950) 53,331.

CASTELLORIZO, island, in Mediterranean Sea. See KASTELORRIZON.

CASTELNAU, kās-těl-nō', **COMTE DE** (FRANCIS DE LA PORTE), French traveler: b. London, England, 1812; d. Melbourne, Australia, Feb. 4, 1880. He traveled extensively in Canada, the United States, and Mexico, and under the protection of the French government undertook an exploration of South America in 1843. After his return to France in 1847, he published *Expédition dans les parties centrales de l'Amérique du Sud* (1850–1861). Castelnau later traveled in Arabia and was successively consul at Bahia, the Cape of Good Hope, and Singapore. At the time of his death he was consul general at Melbourne.

CASTELNAU, Michel de (SIEUR DE LA MAUVISSIÈRE), French soldier and diplomat: b. Mauvissière, Touraine, France, c.1520; d. Joinville, 1592. Of a noble family, he traveled in Italy as a youth and fought in Piedmont under Charles de Cossé, the future Marshal de Brissac. He conducted important diplomatic missions in Switzerland, the Netherlands, Germany, England, and Rome, and fought in the wars of religion from 1560 to 1565. In the latter year he was sent as envoy to Scotland, and in 1572 to England. For a decade from 1575 he was ambassador at the court of Queen Elizabeth, during which time he endeavored to negotiate a marriage between the queen and the duc d'Alençon. His *Mémoires* cover only the period 1559–1570.

CASTELNAU, kās-těl-nō', **VICOMTE Noël Marie Joseph Édouard de Curières de**, French general: b. Saint-Affrique, France, Dec. 24, 1851; d. near Toulouse, March 19, 1944. He entered the Saint-Cyr military school in 1869, served as an officer in the Franco-Prussian War, rose through the successive ranks, studied at the École de Guerre, and was promoted general in 1906. He became chief of staff of Gen. Joseph Jacques Césaire Joffre when, in 1913, the latter was designated as commander in chief in case of war. At the beginning of World War I, Castelnau was placed in command of the army of Lorraine, charged with the defense of Nancy. His forces, drawn up across the gap of Nancy to prevent the army of the crown prince of Bavaria from turning the Allied front, resisted a fierce assault by the Bavarians against the heights of Grand Couronné (Sept. 6 to 12, 1914). By his successful defense of Nancy, Castelnau contributed directly to the victory of the Marne. In 1915, he commanded the French offensive in Champagne and was made chief of the General Staff under the commander in chief. In 1916, he was sent by Joffre to Verdun and saw clearly the need for defending that fortress on the right bank of the Meuse. His recommendations were instrumental in the decision to hold Verdun. After the war, General Castelnau, who was a devout Catholic and an extreme conservative, be-

came active in rightist politics. He served as a deputy in the National Assembly from 1919 to 1924.

CASTELNAU, Pierre de, French ecclesiast: d. Jan. 15, 1208. Archdeacon of Mauguellonne, near Montpellier, he was sent in 1199 by Pope Innocent III, with two Cistercian assistants, to the south of France on a mission to convert or extirpate the Cathari heretics there, who were under protection of Count Raymond VI of Toulouse. After three years of efforts, the archdeacon took the Cistercian habit at Fontfroide, near Narbonne. Thereafter the pope confirmed him as apostolic legate and first inquisitor, and he resumed his labors. At a last stormy interview with Raymond, Castelnau excommunicated the uncooperative count. Shortly afterward one of Raymond's squires, thinking to please him, murdered the legate at an inn on the Rhone. The pope was so enraged at this crime that he proclaimed the "crusade" against the Albigenses (q.v.) conducted with such barbarity.

CASTELNAUDARY, kās-tě'l'nō-dā-rě', commune, France, in the Department of Aude, on a height above the Canal du Midi; 22 miles west-northwest of Carcassonne. It was built by the Visigoths on the site of a former town and was called *Castrum Novum Arianorum* from which its present name has been corrupted. It suffered greatly during the crusade of Simon IV de Montfort l'Amaury against the Albigenses and was captured in 1212; in 1355 it was almost totally destroyed by Edward the Black Prince. It is also famous for the battle fought beneath its walls on Sept. 1, 1632, the troops of Louis XIII defeating Gaston d'Orléans. The town has large grain and flour markets and does a considerable trade in fruit, wool, wine, and cattle; various forms of tiles and earthenware products are manufactured. Saint-Michel, a 14th century church, is located here. Pop. town (1946) 8,073.

CASTELNUOVO, CONTE DI. See **CARMAGNOLA**.

CASTELNUOVO, kās-tāl-nwó'vō, **Enrico**, Italian novelist: b. Florence, Italy, Feb. 16, 1839; d. Venice, Jan. 22, 1915. He spent the greater part of his time in Venice which set the atmosphere for most of his novels. Considered among his best works are *Il professore Romualdo* (1878), *Reminiscenze e fantasie* (1885), and *Il fallo di una donna onesta* (1897).

CASTELNUOVO-TEDESCO, **Mario**, Italian composer: b. Florence, Italy, April 3, 1895. Having studied composition with Ildebrando Pizzetti and piano with Edgardo del Valle de Paz, at the age of 15 he wrote a piece for the piano, *Cielo di settembre*. Among his other works are *La Mandragola* (1926), an opera, *Le Danse del Re David* (1925), *Concerto Italiano* (1924), for the violin and modeled on Italian folksongs, and *Concerto* (first performed 1928), for the piano. His music is programmatic and is harmonic rather than contrapuntal; the shorter forms, especially songs, were his specialty. He made his home in the United States.

CASTELO BRANCO, kās-tě'l'ōō brāng'-kōō, **Camilo** (also **CAMILLO CASTELLO BRANCO**; **VISCONDE DE CORREIA-BOTELHO**, kōōr-rā'yā bōō-

tā'lyōō), Portuguese novelist and poet: b. Lisbon, Portugal, March 16, 1825/1826; d. São Miguel de Seide, Minho, June 1, 1890. Orphaned at an early age, he was taken to a village in Tras-os-Montes by his sister where he led an erratic life. He studied for several professions but after a short journalistic career he took minor orders. His restless nature, however, prevented his adherence to this course, and he abandoned it to resume a feverish literary activity. In 1885 he was created a viscount in recognition of his literary accomplishments. Five years later, having lost his sight and suffering from a nervous disease, he committed suicide. He was particularly known for his novels of manners such as *Amor de perdição* (1862) and *Amor de salvação* (1864).

CASTELO BRANCO, kās-tā'l'ōō vrāng'-kōō, commune, Portugal, capital of Beira Baixa Province; 114 miles northeast of Lisbon. It is an agricultural trading and processing center; manufactures include woolen goods, candles, pottery, and furniture. Its episcopal palace with its formal gardens is of interest. Pop. (1940) 9,293.

CASTELVETRANO, kās-tě'l-vā-trā'nō, commune, Sicily, in the Province of Trapani; 29 miles south-southeast of the town of Trapani, on a rocky hill about 8 miles from the sea. Wine is the chief agricultural product, and furniture is the most important manufacture. The ruins of the Greek city Selinus are nearby. Pop. (1951) 30,195.

CASTELVETRO, kās-tāl-vā'trō, **Lodovico**, Italian critic and philologist: b. Modena, Italy, about 1505; d. Chiavenna, Feb. 21, 1571. His works include a translation and commentary on Aristotle's *Poetics* (1570), and expositions on Cicero's *Rhetorica* (1553), Dante, and Petrarch.

CASTI, kās'tě, **Giovanni Battista**, Italian poet and adventurer: b. Acquapendente, Italy, Aug. 29, 1724; d. Paris, France, Feb. 5, 1803. Having studied and taught at the seminary in Montefiascone, he became court poet in Florence in 1764. There he met Emperor Joseph II, who liked his wit and personality and took him to Vienna in 1769. Casti went to Russia in 1778 and was received by Catherine II with great honors. This, however, did not prevent him from satirizing her in his *Poems Tartaro* (1787), for which Joseph II exiled him. He returned, however, to become poet laureate from 1790 to 1796, finally settling in Paris in 1798. The first to write truly original comic operas in Italian, Casti's fame rests mainly on his *Novelle Galanti* (1793, corrected edition), a collection of 48 short stories in verse. Most are of a licentious turn, as in his poem *Animali Parlanti* (1802), in which, through imaginary antediluvian animal characters, he symbolizes the conflict between the conservative regimes and the revolutionary ideas to which he was sympathetic.

CASTIGLIONE, DUC DE. See **AUGEREAU**, **PIERRE FRANÇOIS CHARLES**.

CASTIGLIONE, kās-tě-lyō'nā, **CONTE Baldassare**, Italian diplomat and writer: b. Casatico, near Mantua, Italy, Dec. 6, 1478; d. Toledo, Spain, Feb. 7, 1529. He studied in Mantua and

at the age of 18 entered the service of Duke Ludovico Sforza. In 1499 he became attached to the service of Francesco Gonzaga, duke of Mantua, whom he accompanied on an unsuccessful campaign in Spain. Five years later he transferred to the small but brilliant court of Guidobaldo II, duke of Urbino. Here in a relaxed but intellectual atmosphere he was able to devote much of his time to literary pursuits. He served not only as an accomplished courtier but also as a soldier and as an ambassador, and in 1506 was sent on a mission to Henry VII of England where he received the Order of the Garter for his duke. In Rome, he met and befriended Raphael, whose fine portrait, now in the Louvre, clearly reveals his personality. In 1524 Pope Clement VII sent Castiglione as papal nuncio to the court of Emperor Charles V who later offered him the bishopric of Avila. His Spanish mission is generally considered a failure, since it did not effect the desired reconciliation nor did it prevent the sack of Rome by the Bourbons in 1527; but at least part of the blame should go to the wavering attitude of the pope himself.

Castiglione was a true humanist and one of the most representative figures of the Italian Renaissance from an ethical, literary, and political viewpoint. His fame rests chiefly on his prose dialogue, *Il Cortegiano* (q.v.), in which he describes the true Italian gentleman of his time; it is considered one of the most important works of the 16th century. Sometimes known in Italian as *Il Libro d'Oro*, it was first printed by the Aldine Press of Aldo Manutius in 1528. The first English translation, made by Sir Thomas Hoby as *The Courtier of Count Baldessar Castilio* (1561), had a considerable influence on Sir Thomas Wyatt, Earl of Surrey, Sir Philip Sidney, and Edmund Spenser. Castiglione also wrote poems in Italian and Latin.

Consult Cartwright, Julia, *Baldassare Castiglione* (London 1908) for reference and bibliography.

CASTIGLIONE, CONTE Carlo Ottavio, Italian scholar: b. Milan, Italy, 1784; d. Genoa, April 10, 1849. He is best known for his edition of some of the fragments of Ulfilas' Moeso-Gothic Bible which were discovered in 1817 by Cardinal Mai. Castiglione also published a work in 1826 in which he sought the origin and history of the Barbary towns whose names appeared on Arabic coins.

CASTIGLIONE, Giovanni Benedetto (called *IL GRECHETTO*), Italian painter and etcher: b. Genoa, Italy, about 1610; d. Mantua, 1665.¹ A pupil of G. B. Paggi and G. A. De Ferrari, he was also influenced by Bernardo Strozzi, another leading painter of the school of Genoa. He was active in several centers but spent most of his life after 1639 at Mantua, where he was court painter of the duke of Mantua. Best known as a painter of animals, he chose religious and mythological subjects which allowed him to include large numbers of animals, such as Noah's ark, Abraham's journey, the nativity of Christ, pastoral myths and sacrifice scenes, as in the handsome *Ancient Sacrifice* in the Palazzo Durazzo in Genoa. His brother Salvatore and his son Francesco worked in his shop, the latter succeeding him as court

painter at Mantua. Castiglione's etchings are also well known, their free drawing and handling of light suggesting contact with Rembrandt's etchings.

Consult Delogu, G., *G. B. Castiglione detto Il Grechetto* (Bologna 1928).

CASTIGLIONE DELLE STIVIERE, *käs-tē-lyō'nā dāl-lā stē-vyā'rā*, commune, Italy, in Mantova Province; 22 miles northwest of Mantua. Located in the fertile Po plain, it is a busy agricultural market town; silk spinning is the principal industry. In 1404 it came under the Gonzaga, lords of Mantua, and was the seat of the principality under a branch of the family until early in the 18th century. Near here Napoleon won a decisive victory over the Austrians under Dagobert Siegmund von Wurmser on Aug. 5, 1796. Pop. (1951) 9,131.

CASTIGLIONE OLONA, [*käs-tē-lyō'nā olō'nā*], commune, Italy, in the Province of Varese; 27 miles northwest of Milan. The principal manufactures are cotton goods, textile machinery, and combs. The town is most famous for its frescoes by the 15th century Florentine artist Masolino da Panicale; the Collegiate Church, built by Cardinal Branda da Castiglione, contains the fresco of the life of Christ, and the life of St. John the Baptist is portrayed in the Baptistery. Pop. (1951) 3,643.

CASTILE, *käs-tēl'* (Span. *CASTILLA*, *käs-tē'-[l]yā*), region and former kingdom, Spain, traditionally divided into Old Castile (*Castilla la Vieja*) and New Castile (*Castilla la Nueva*), of which Burgos and Toledo were respectively the capitals. Burgos remains the capital of the modern region of Old Castile, but Madrid has replaced Toledo as capital of New Castile. The name "Castile" seems to have been derived from the numerous *castillos* (*castella* in Latin) constructed by nobles in that territory for defense against Moorish incursions during the Christian reconquest of Spain.

Occupying the geographic center of the Iberian Peninsula, New Castile included the Moorish kingdom of Toledo. Its present-day regional area, approximately that of the historic area, includes the five provinces of Ciudad Real, Cuenca, Guadalajara, Madrid, and Toledo. On the north it is bordered by Old Castile and Aragón; east by Aragón and Valencia; south by Murcia and Albacete; and west by Extremadura. It has an area of 27,933 square miles and a population of 3,559,809 (Dec. 31, 1950). The largest city is Madrid with a population of 1,618,435 (1950) and the next largest is Toledo (40,243). All the other cities have populations of less than 35,000.

Old Castile, adjoining New Castile to the north, is separated from it by the mountain barriers of the Sierra de Gredos, Sierra de Guadarrama, and Sierra de Ayllón. Historically its confines were even more vague and shifting than those of New Castile. In its present-day extent it comprehends the six provinces of Santander, Burgos, Logroño, Soria, Segovia, and Ávila. The region is boot-like in form, with Ávila the toe, Soria the heel, and the Bay of Biscay littoral of Santander Province the top. The largest city is Santander (102,464) and next largest Burgos (74,063), the regional capital. Few other cities, apart from provincial capitals, have populations in excess of 5,000.

¹ These dates have been regarded by modern scholarship as more nearly correct, although 1616-1670 have been repeated many times.

The greater part of Spain's central plateau is in Castile. The average elevation above sea level in New Castile is about 1,970 feet, while in Old Castile—the maritime province of Santander excepted—it is about 2,300 feet, and in the provinces of Burgos and Soria the elevation rises to 2,950 feet. Here are the headwaters of the Duero, Tagus, Guadiana and Júcar rivers. The plains of Castile are hemmed in on all sides by mountain ranges. The climate is continental—dry and very cold in winter, with temperatures recorded to $-64^{\circ}\text{F}.$; while summer temperatures rise to $117.6^{\circ}\text{F}.$ Winter snowfalls are heavy and the snows on the cordilleras last until April.

Largely arid and climatically unfavorable to agriculture, Castile is in the main a pastoral land. However, there is cultivation of cereals—chiefly wheat and barley, also potatoes, beans, and grapes. In southeastern New Castile the famous Valdepeñas, Tomelloso, and other wines are produced. Olive production is almost nonexistent, and no citrus fruit trees can be grown due to climatic conditions. The Castilian plain is treeless, ruthless felling having destroyed its ancient groves. What little forest growth remains in New Castile is in the mountainous parts of Cuenca where there are fairly extensive pine stands. On the other hand, in Old Castile there are numerous and extensive pine forests, especially in Soria and Segovia, which furnish large supplies of resin. This forest industry, with cattle raising, cheese-making, viticulture (in Burgos, Soria, and Ávila), vegetable and fruit canning in Logroño, cloth weaving for home consumption, wood exploitation (in Soria, Burgos, and Segovia), and milling, complete the picture of Old Castile's industrial activity.

In the southern part of Ciudad Real Province (New Castile) coal, mercury, and other minerals are mined in the vicinity of Puertollano and Almadén.

History.—According to tradition the first independent count of Castile was Fernán González (c.910–970). Before his time Castile had been ruled by vassals of the kings of Asturias and León who may have held the title of count. In 940 Fernán González revolted against King Ramiro II of León (r. 931–951), but was defeated and imprisoned. Several years passed before he recovered his liberty and countship. However, from 950 his name appears on Castilian documents without mention of the king of León, from which it is inferred that by then he had secured Castile's independence. A skillful politician as well as a warrior, he styled himself "Count by the Grace of God." In 955 he defeated the Moors at San Esteban de Gormaz.

The countship passed through various hands until it was seized by Sancho III, king of Navarre (r. 1000–1035), whose queen was a sister of Count García Sánchez of Castile, after the latter's murder in 1028. Sancho III also held the lordship of Aragon and conquered León. On adding Castile to his dominions, he raised it to the dignity of a kingdom and added to his own titles that of King Sancho I of Castile. In 1035 the crown of Castile passed to his second son who ruled as Ferdinand I (the Great). Four years later Castile and León were united. The two realms were separated in 1065, but in 1072 were reunited by King Alfonso VI (Alfonso el Bravo) of León who ruled Castile as Alfonso I. Subsequently the kingdoms were again separated but were finally reunited in 1230 under Ferdinand III (el Santo)

of Castile. Other noted kings of Castile include Alfonso X (el Sabio) and Pedro the Cruel. Isabella of Castile married Ferdinand of Aragon in 1469 and acceded to the throne of Castile in 1474, her husband becoming king of Aragon in 1479. Thenceforth Castile and Aragon were united in the Spanish monarchy. See also SPAIN—History.

CASTILHO, kâsh-tê'lyôo, VISCONDE Antônio Feliciano de, Portuguese poet: b. Lisbon, Portugal, Jan. 28, 1800; d. there, June 18, 1875. Although almost blind, he received his education with the help of his brother Augusto and later studied law at the University of Coimbra. His first poetical composition, *Cartas de Echo e Narciso* (1821), published while he was a student, won him great celebrity. He excelled in pastorals, to which class *A Primavera* (1822) and *Amor e Melancolia* (1822) belong. He was a leader of the romantic movement in Portugal. Among his other literary accomplishments are *A Noite do Castello* (1836), a translation of Ovid's *Metamorphoses* (1841), and a free adaptation of Shakespeare's *Midsummer Night's Dream* and Goethe's *Faust*.

CASTILIAN DIALECT, the official literary tongue of Spain. See SPAIN—Language.

CASTILLA, kâs-tê'yâ, Ramón, Peruvian soldier and politician: b. Tarapacá, Chile, Aug. 27, 1797; d. Arica, May 25, 1867. He fought in the war for independence (1820–1826) and in the civil war (1841–1845). In 1837, under President Augustín Gamarra, he was minister of war. Elected president of Peru in 1845, he was succeeded in 1851 by José Rufino Echenique, but overthrew him in 1855; three years later he was again elected to the presidency. He introduced several important reforms, such as the abolition of slavery (1856) and the promulgation of a new constitution (1860) which remained until 1920. In 1862 he was succeeded by Miguel San Román. See also PERU—History.

CASTILLA ELASTICA (known also as the MEXICAN RUBBER TREE, PANAMA RUBBER or ULE RUBBER), a member of the family Moraceae (Mulberry family), it is the principal source of rubber in Mexico and Central America. A fast-growing tree, especially when young, this species is characterized by large, oval, coarse leaves (18 x 6 inches), monoecious flowers, and fleshy, orange-red fruits (2 inches in diameter), composed of numerous drupes. The milky juice, which is obtained by tapping, coagulates in the air, a process often hastened by adding various plant substances. This crude rubber was well known to the early inhabitants of Mexico who made balls and other articles from it. It is also used for waterproofing of coats, hats, shoes, and other things. Cultivation of this and other species of the same genus, although attempted on a large scale, has not been so successful as that of other rubber-bearing plants, mainly because of the smaller yield and the difficulties encountered in tapping operations. The Mexican rubber tree is also used for medicinal purposes, and its bark is supposed to be a source of paper. Other species of the genus yield rubber exported from various Central American countries and especially Brazil. Although widely used, *Castilloa* is an incorrect version of the generic name.

CASTILLEJO, kās-tē-lyě'hō, **Cristóbal de**, Spanish poet: b. Ciudad Rodrigo, Salamanca Province, Spain, c.1490; d. Vienna, Austria, c.1550. Before the age of 15 he entered the service of Archduke Ferdinand, younger brother of Charles V, as a page. Upon the king's death in 1515 he became a monk at San Martín de Valdeiglesias where he remained until 1525 when he was made Archduke Ferdinand's secretary. While living in Vienna he led a rather licentious life despite his indescribable hardships. Endeavoring to remedy his plight, Charles V assigned him a 2,000-florin pension in 1548, but the poet died soon afterward. Although Castillejo does not rank among the lyricists of his time, few surpass his satiric venom and festive vein. Writing in the traditional style, facile, elegant, he satirized poets like Boscán Almogaver and Garcilaso de la Vega who were introducing the style and satirical combinations of the Italian poets. In addition to his versions of the Latin poets, he wrote numerous songs, ballads, and religious and moral works. Among his better known works are *Scrmon de Amores*, *Diálogo . . . de las mujeres*, and *Diálogo entre el autor y su pluma*, all of which are examples of his charming simplicity and delightful wit.

CASTILLEJOS, MARQUÉS DE LOS. See PRIM Y PRATS, JUAN.

CASTILLO, Bernal Díaz del. See DIAZ DEL CASTILLO, BERNAL.

CASTILLO, kās-tē'yō, **Ramón S.**, Argentine statesman: b. Catamarca, Argentina, Nov. 20, 1873; d. Buenos Aires, Oct. 12, 1944. The son of Rafael and Maria B. Castillo, he studied at the National University in Buenos Aires and became secretary of the Commercial Court of the City in 1893. Thereafter he held various legal and pedagogical positions. He entered politics in 1930 and was elected senator from Catamarca in 1932, serving until 1935. He successively held the posts of minister of public instruction and minister of the interior, and became vice president of Argentina and president of the senate in 1938. When President Roberto M. Ortiz resigned in 1940 because of ill health, Castillo became acting president, and president, governing by decree, after April 1941. Extremely conservative, he alienated Argentina from her sister republics by withholding cooperation in the United Nations in accordance with his policy of "prudent neutrality." He authorized repressive measures against the Argentine press, restricted labor, and curtailed civic liberties.

CASTILLO DE SAN MARCOS, national monument. See NATIONAL PARKS AND MONUMENTS.

CASTILLO NAJERA, kās-tē'yō nā'hā-rā, **Francisco**, Mexican physician and diplomat: b. Durango, Mexico, Nov. 25, 1886. The son of Romualdo Castillo and Rosa Nájera, he received his degree in medicine at the University of Mexico in 1903 and did further work in Paris and Berlin. He was director of the Juárez Hospital, Mexico City, 1918-1919, and in the latter year was professor of urology. In 1920 he became director of the army medical school and from 1921 to 1925 was a member of the international commission for the campaign against yellow fever.

In 1922 Castillo Nájera began his diplomatic career as minister to China, followed by the same position in Belgium (1927-1930), Holland (1930-1932), and France (1933-1935). He was ambassador to the United States from 1935 to 1945, at which time he returned to Mexico to become minister of foreign affairs. He served as Mexican delegate to the United Nations and in June and July 1947 was president of the Security Council.

CASTILLO SOLORZANO, kās-tē'lyō sāl-lôr'thā-nō, **Alonso de**, Spanish author: b. Torrellas, Spain, c.1584; d. probably at Zaragoza, about 1647. Although he published two volumes of humorous verse, *Donaires del Parnaso*, he is chiefly remembered as a novelist. Two of his works, *La niña de los embustes* (1632) and *Aventuras del bachiller Trapaza* (1634), were used in *Gil Blas* by Lesage. He also wrote several plays which were widely popular.

CASTILLON, kās-tē-yōn', or **CASTIL-LON-ET-CAPITOURLAN**, kās-tē-yōn' nā kā-pē-tōōr-lān', commune, France, in the Department of Gironde, on the Dordogne River; 26 miles east of Bordeaux. Beneath its walls, on July 17, 1453, was fought the battle which ended the Hundred Years' War, when the English met a defeat which resulted in the return of Gascony and Guyenne to France after being held by the English for nearly 300 years. Part of the battle was described by Shakespeare in the fourth act of *King Henry VI, Part I*. Pop. (1950) 3,071.

CASTINE, kās'-tēn, **Baron Vincent de**, French soldier: b. Oleron, France, 1650; d. there, about 1722. He went to Canada in 1665, established a mercantile house at Penobscot (now Castine), Me., in 1687, and married the daughter of the Penobscot chief. In 1696 he captured Pemaquid. He assisted in the defense of Port Royal in 1706 and was wounded there the following year. His son, who succeeded him in command of the Penobscots, was made prisoner and taken to Boston in 1721.

CASTING, the running of melted metal into a mold, so as to produce an object in metal having the shape of the mold. The casting of type is done by composing machines (q.v.). See CAST STEEL; FOUNDRY PRACTICE; and IRON—Cast Iron.

CASTING AWAY OF MRS. LECKS AND MRS. ALESHINE, *The*, a humorous story by Frank R. Stockton, published in 1886. Two widows, one with a son in business in Japan, decide to see the world and set out for the Orient. On the way they are shipwrecked but escape in a leaky boat which, however, finally sinks under them. They make their way to a small coral island with their companion, Mr. Craig, who tells the story. On the island they take possession of the summer place of the Dusantes and make themselves at home. Ruth Edgerton, a missionary's daughter, and her father then join the party. The two old ladies decide, among other things, that Mr. Craig should marry Miss Edgerton, and in their own inimitable way they accomplish their end. Before leaving the island, they write a note to the owners of the house where they temporarily stayed. In *The Dusantes* (1888), a continuation of the tale, the widows and the Dusantes meet back in the states under exciting circumstances.

Representative of Stockton's unique method of storytelling, these absurd tales are told in a gracefully realistic manner.

CASTLE, kàs"l, Egerton, English novelist: b. London, England, March 12, 1858; d. there, Sept. 20, 1920. He was educated in Paris, Glasgow, and at Cambridge. After a brief military career he turned to journalism, and was publisher of the *Liverpool Mercury*. From 1885 to 1894 he served on the staff of the *Saturday Review*. Among his numerous works are *Consequences*, a novel (1891), *Saviolo*, a play (1893, co-author W. H. Pollock), *Young April*, a romance (1899), *The Star-Dreamer* (1903), *Panther's Cub* (1910), *Wolf Lure* (1917), and *New Wine* (1919). A great number of his novels were written jointly with his wife, Agnes Sweetman Castle (d. 1922), including *The Pride of Jennico* (1898; later dramatized) and *The Bath Comedy* (1899; dramatized as *Sweet Kitty Bellairs*).

CASTLE, Vernon (originally VERNON BLYTHE), English aviator and dancer: b. Norwich, England, May 2, 1887; d. Fort Worth, Texas, Feb. 15, 1918. He was educated for civil engineering at Birmingham University. In 1906 he came to the United States and the following year made his theatrical debut in *The Girl Behind the Counter*. His outstanding talent, however, was dancing; he originated the one-step, turkey-trot, and Castlewalk. After his marriage in 1911 to Irene Foote of New Rochelle, N. Y., he opened a dancing school and devoted himself entirely to exhibitions and teaching; he became very popular in Paris in 1912. In 1915 he took up aviation, received his pilot's certificate in the United States, and in February 1916 enlisted in the Royal Flying Corps. He served in France and during the next year made about 200 missions over enemy lines. In 1918 he was transferred to Fort Worth, Texas, as an instructor but was killed in a collision with a cadet. He was known not only for his dancing but won the respect of military officers for his spectacular flying.

CASTLE, William Ernest, American zoologist: b. Alexandria, Ohio, Oct. 25, 1867. He studied at Denison University and in 1894 received his Ph.D. from Harvard. After serving in various teaching capacities at Ottawa (Kans.) University, University of Wisconsin, and Knox College, he became assistant professor of zoology at Harvard in 1903, being promoted to a professorship, 1908-1936. He wrote numerous articles on embryology, animal morphology, and heredity; his books include *Heredity in Relation to Evolution and Animal Breeding* (1911), *Genetics and Eugenics* (1912), *Genetics of Domestic Rabbits* (1930), and *Mammalian Genetics* (1940).

CASTLE. See CASTLES AND CHÂTEAUX.

CASTLE CLINTON (at one time CASTLE GARDEN and later the NEW YORK CITY AQUARIUM), originally a small, partially submerged, rocky island known as Capske (Copsie, or Copsy), about 200 feet off the shore of the Battery, at the southwestern tip of New York City. In November 1807 the island was given by the city to the federal government for the construction of a fort, completed in 1811 and called West Battery. One of the city's main defenses in the War of 1812, West Battery and Fort Jay on Governors

Island guarded the entrance to the East River. At the war's close in 1815, West Battery was renamed Castle Clinton in honor of DeWitt Clinton, mayor of the city. By an act of Congress, at the end of March 1822, it was ceded back to the city. During its entire history, not one shot had ever been fired at the enemy.

On June 12, 1824, it was leased as an amusement place and opened the following July 3 as Castle Garden. The building, now with a roof added, was used as a reception place, theater, music hall and opera house, and in the 1840's and early 1850's housed numerous exhibitions and fairs. Lafayette was given a reception there in 1824; Jenny Lind, sponsored by P. T. Barnum, made her American debut there on Sept. 11, 1850; and Samuel Morse, in 1835, presented one of the earliest demonstrations of the telegraph. Other notables to have visited Castle Garden were Andrew Jackson, 1832, John Tyler, 1843, and the Hungarian patriot Lajos Kossuth, 1851. In 1855 it became a landing depot for immigrants and on August 3 of that year received its first group of aliens. It remained as an immigration center until 1890 when the federal government moved the station to Ellis Island.

In 1848 the city decided to enlarge Battery Park by extending the mainland, and by 1869 enough land fill had been added to surround Castle Garden on three sides. In 1896 the building was opened as an aquarium which was taken over by the New York Zoological Society in 1902. The aquarium was moved in 1941 to the Bronx Zoo but will be housed in a new building at Coney Island, planned to open about 1955. The original fort, Castle Clinton, was established as a national monument on Aug. 12, 1946, and is being restored; it is under the jurisdiction of the National Park Service. See also AQUARIUM.

CASTLE GARDEN. See CASTLE CLINTON.

CASTLE HILL, hill near Benedictine monastery at Cassino, Italy, which was captured by Indian troops, March 15-20, 1944, after bitter fighting in World War II.

CASTLE OF OTRANTO, The, a novel by Horace Walpole, published in 1764. It owes its importance to the fact that it was the first example of the so-called Gothic romance, a type of fiction which, in the hands of writers like Anne Radcliffe, became highly popular in the late 18th century as a reaction against the sentimental and realistic novels of the school of Richardson; it also prepared the way for the great exploitation of medieval romance in the historical novels of Sir Walter Scott. Intrinsically, *The Castle of Otranto* is interesting chiefly by virtue of its absurdity. The scene is a medieval castle with battlements, trapdoors, and intricate subterranean cloisters; the theme, the mysteries which it harbors within its walls. The plot, involving a gloomy tyrant, a persecuted wife, a lovely young prince, and two romantic girls, employs the supernatural at every turn, such as a gigantic helmet crashing from heaven into a courtyard, or an ancestral portrait stepping forth from its frame and becoming a ghost. These strange matters cause many difficulties for the chief characters but in the end lead to a somber yet satisfactory ending. Walpole based his novel upon his little pseudo-Gothic house at Strawberry Hill, near London, a house which was famous in his time

for its break with the strong neoclassical principles then in vogue.

CASTLE PINCKNEY, national monument. See NATIONAL PARKS AND MONUMENTS.

CASTLE RACKRENT, a novel by Maria Edgeworth, written in 1801. Although it was her first novel, it is still regarded by many critics as her masterpiece. It belongs to that series of novels dealing with Irish life, which elicited the praise of Sir Walter Scott and other contemporaries. The opportunity which Miss Edgeworth had of studying Irish conditions at first hand enabled her in these novels to draw a powerful and substantially accurate picture of contemporary conditions in Ireland. The theme of *Castle Rackrent* is the wasting fortunes and the final disaster of an honorable Irish family as the result of carelessness, improvidence, folly, and absenteeism. The story, of only a few score pages, is told by a faithful old retainer of the family, Thady Quirk, who lives through the successive reigns of Sir Patrick, who drank himself to death; of Sir Murtagh, the close-fisted, who wasted his substance in lawsuits; of the dashing Sir Kit, an absentee landlord, who married a Jewess whom he confined for seven years in her chamber, and who met his death in a duel; and finally of Sir Condy, under whose easy ways the estate finally passed from the hands of the Rackrents into those of creditors, particularly Jason Quirk, the son of old Thady, who bought the debts of the property. The story is told in a vigorous manner, full of local touches of a lively character.

CASTLE SHANNON, kás'í shán'ün, borough, Pennsylvania, in Allegheny County; altitude 820 feet; 6 miles south of Pittsburgh; on the Pittsburgh and West Virginia and the Pittsburgh railways. It is a residential community governed by a borough council and a burgess. Founded in 1782, it was incorporated in 1918. Pop. (1950) 5,459.

CASTLEBAR, kás'í-l-bär', urban district, Ireland, capital of County Mayo; 140 miles northwest of Dublin; on the Castlebar River. It is situated in a cattle-raising and potato-growing region. The town was founded by Sir John Bingham and received its charter in 1613. In 1641 the Parliamentary forces under Sir Henry Bingham surrendered to the Irish Confederates under the earl of Mayo but later were massacred at Shrule Bridge by Edmund Bourke, a clansman of the earl. Nearby is the site of the battle known as "Castlebar Races" in which the French general, Jean Robert Marie Humbert, defeated Gen. Gerald Lake in 1798. Pop. (1946) 4,951.

CASTLEFORD, kás'í-l-fërd, urban district, England, in West Riding, Yorkshire, on the Aire River; 10 miles southeast of Leeds. It is in a coal mining region, and bottles, pottery, machinery, and chemicals are manufactured. Pop. (1951) 43,116.

CASTLEMAINE, kás'í-l-mān, town, Australia, in the State of Victoria; 65 miles northwest of Melbourne. It owes its importance to the mining industry carried on in the neighborhood, the most important products of its mines being gold, flagstone, and slate. Its goldmines

are famous as being among the original ones discovered in Australia. Pop. (1947) 5,809.

CASTLEREAGH, VISCOUNT. See STEWART, ROBERT.

CASTLES AND CHATEAUX. The English word castle is derived from the Latin *castrum*, itself a diminutive of *castrum*, a fort. Thus, from its origin, it involved the concept of defensibility. However, in the Vulgate, *castrum* refers to villages whose buildings were fortified. Hence a castle is essentially a defensible home. The French word *château*, with the same root, has come even more to mean a house, usually a large country house.

The Ancient Castle.—Little need be said about fortifications in Egypt. Early in its history, the royal palaces were fortified with towers and parapets, and that tradition lingered on in the homes of the ruling class perhaps after its real military reason had gone. With the expansion of Egypt up the Nile in the 12th dynasty, there was real need for defense on the southern frontier. There the fort of Semna was built with heavy brick walls reinforced by bonding members of timber and by massive buttresses.

The ruling caste in Assyria, renowned in literature for its ferocity, was in constant danger both of internal unrest and of attack from without. Hence thick walls of mud brick bounded such cities as Khorsabad; paired towers flanked the

Fig. 1. Citadel, Tiryns.

city gates, with other battlemented towers at intervals along the wall. From these walls and towers in case of attack, the Assyrian archers could discharge their arrows in comparative safety. At one point the city wall was widened into a platform for the palace of Sargon II (722-705 B.C.) which thus became a bastion to protect Khorsabad. Chariots could drive up ramps to the broad top of the wall and into the courts of the one story palace. The gates to the palace, its walls, and even its courts were also provided at intervals with battlemented towers. The palace was arranged around several courts, the men's or royal court with its suite of state apartments, a servants' court or khan, presumably a women's court or harem, and finally an area for religious purposes with its pyramidal tower or ziggurat built up in seven stages. Guardian monsters carved in stone with the legs and body of a lion—or sometimes a bull, the wings of an eagle, and the head of a man flanked the main entrance. Friezes sculptured in low relief in the royal apartments commemorated the king's prowess in warfare or in the hunt. Rugs covered the floors, and no doubt textiles helped to create a sumptuous atmosphere.

The Greek chieftains of the Mycenaean period likewise fortified their palaces. The citadel at Tiryns (Fig. 1), built toward the end of the second millennium B.C., has walls 26 feet thick that approximately follow the contours of its hilltop. These walls are built of "Cyclopean" masonry;

that is, large blocks of stone of irregular shape fitted together. Narrow passagelike chambers covered by corbel vaults penetrate part of the wall from within and probably served as storage space for provisions and weapons. The chariot entrance led up a ramp so arranged that the fortress wall was on the right of the chariot. Since the Greek warrior carried his shield on his left arm and his spear or sword in his right hand, this meant that, during his approach to the gate, his right or unprotected side was exposed. If an attacking party succeeded in forcing the first gate, they found themselves in a narrow alley flanked on both sides by strong walls and with secondary gates at either end, one on the right leading to the lower ward or bailey, the other to the palace area. Still another wall divided the palace from the bailey so that even if the latter were captured, the task of the attackers was by no means over. Narrow postern gates, too small and their approaches too steep for chariots, gave secondary access to the lower ward and to the palace proper. If, however, a peaceful visitor arrived, he might drive his chariot through the gates, through the outer court separated by an entrance pavilion or propylaea from the middle court where he could leave his steeds to enter through a second propylaea into the inner court in front of the men's suite or megaron with its open hearth. This was the center of life in the palace; around it were grouped the quarters for sleeping and other activities of life, and although there was a secondary court and suite of rooms for the womenfolk, the thalamus, approached from the megaron by circuitous routes, nevertheless men and women mingled in the megaron in ordinary daily life. While waiting for Odysseus' return, Penelope worked her embroidery and entertained her suitors here, but retired at night with her maidens into the thalamus.

The Acropolis in Athens, a civic and religious center in historic times, offered great natural facilities for defense; its abrupt slopes, where necessary, were further reinforced by walls. As Athens grew, however, Themistocles walled in the city, about 480 B.C. Rome likewise was defended by walls, parts of which still survive. The old republican wall was outgrown before the empire, but extensive later walls were added, as for example by the Emperor Aurelian, begun 271 A.D.

During the centuries of the *pax romanum*, except near the frontiers, no reason existed to confuse domestic architecture with provision for defense. Though still almost a century would elapse before the first serious incursion of the barbarians through the Rhenish-Danubian frontier, it is almost symbolic that Diocletian in the late 3d century should build his palace at Spalato in what is now Yugoslavia. At least the location brought him closer to the frontier than Rome. Moreover, the plan of his palace (Fig. 2) was influenced by the Roman military camp. The latter was laid out foursquare, its gates in the center of each side with straight roads connecting them and dividing the camp into quarters. Likewise a square wall enclosed Diocletian's palace, and streets bisected it in both directions. Three of the walls were defended by towers at the corners, in pairs around the gates, and at mid-points between the corners and the gates. The fourth wall built on the very shore of the Adriatic needed no defense; it could provide an

open gallery along its length as a promenade. This lack of fortification on the sea front again is suggestive; though Diocletian may not have anticipated an actual assault, it was clear that if one should occur, it would come by land, not by sea. The tribes along the Danubian frontier were landmen.

The Medieval Castle.—The heyday of the castle as an architectural form in western Europe was the Middle Ages from 1000–1500. For this the feudal system was responsible. The weakness of the royal power permitted the nobility to become nearly independent in fact if not in theory. The system allowed, if it did not actually encourage, the nobility to prey when possible on their neighbors or on the surrounding countryside; therefore, they were compelled to make their own homes as nearly impregnable as might be. Since these conditions existed over most of Europe with some local variations, it follows that the basic ideas of the castle existed alike in France and Germany, in Spain and England, and

FIG. 2. Palace of Diocletian, Spalato.

that the variations from country to country are less marked than the similarities.

Although after the Norman Conquest of 1066 the royal power in England was generally stronger than it was on the Continent, the Norman feudal barons required strongholds to control the land and the conquered Saxons. One such, of great historical interest, is the Tower of London begun in 1078 by William the Conqueror. Though complicated by extensive later additions, the White Tower was the nucleus, the keep, so-called because the lord and his garrison lived or kept there. Several stories high with double walls, small windows, and spiral stairs in the corners of the tower, it was quite typical of its day. Perhaps the most interesting feature is the Chapel of St. John, a characteristic small Romanesque church. Such chapels were customary in the larger castles not only to serve the religious needs of the household, but doubtless also were used by the lord of the castle for private conferences since the hall would rarely be empty of retainers.

Hedingham Castle (Fig. 3), Essex, built about 1130, the home of the de Veres, was one of the

Fig. 3. Hedingham Castle.

most perfect of the Norman keeps until it was gutted by fire during World War I. Solidly built with double walls of stone 20 feet thick, its corners were still further reinforced. A flight of steps, arranged like the ramp at Tiryns to expose the unshielded side of an attacker, led up to the door at the level of the second floor. This door entered the great two-storied hall, the center of life for the garrison. Aside from small areas within the thickness of the walls where the meager sanitary facilities of the castle were located, this hall was the interior. Within it the family and its retainers ate, slept, and had their being. Such light as there was came from the few small windows high up in the wall and utterly inadequate by modern standards, but necessarily kept to a minimum not only for defense but for warmth. Since window glass was not available, any warmth on the interior could be preserved only by closing the windows with shutters which excluded even the little light these openings might afford. For heating, a fireplace was built in the center of one side of the hall, its chimney rising in one of the middle buttresses of the outer walls. The ceiling of the hall was carried on a single great arch that spanned the hall from side to side. The familiar round arch of the Romanesque style and its characteristic moldings adorn fireplace, door, windows, and indeed wherever architectural emphasis was required. Above the hall was another chamber of the same size, also warmed by a fireplace. Probably the womenfolk of the household carried on their activities here, and it may also have served as private quarters for the de Veres. Access to it as well as to the ground floor was provided by spiral stairs in one corner of the keep. Since there was no other entrance to the ground floor it could have served as a dungeon for prisoners but was probably used mostly for storage purposes. If the space provided for the varied purposes of living in Hedingham Castle seems restricted, it was clearly because the necessity for defense superseded comfort. Still Hedingham was not quite so confined as this description implies; wooden structures that could be destroyed if a siege were imminent once covered the door and the stairway. Traces of the roofs where they joined the masonry of the keep are still visible.

One of the largest of the Norman keeps was Colchester Castle, Essex, of the late 11th century,

measuring 152 by 111 feet exclusive of the towers, so large in fact that walls subdivided the interior. The upper stories at Colchester have been destroyed, but the keep at Rochester, Kent, rises to a height of more than 100 feet. It was begun by Archbishop William of Corbeil (d. 1136). Somewhat later, perhaps built about 1150, is the small but delightful Castle Rising, Norfolk. In addition to the exceptional richness of its arcades and moldings, we have here an example of a fore building designed to enclose the stair. The door at the ground level gave access to the stairs that led up along the wall of the castle to the main door at the second story.

Perhaps the desire for ampler accommodations contributed to the development of the courtyard castle whose towered and battlemented walls enclosed a more or less extensive bailey or perhaps more than one. Thus in the early 13th century at Pembroke Castle in South Wales, the walls encircling the outer and inner bailies followed the contours of the hilltop with towers at each change of direction. Within the bailey, its entrance guarded by a heavily fortified gatehouse,

Fig. 4. Coucy-le-Château.

was ample room not only for living quarters but for livestock. The concept of the keep was not abandoned, however; it was merely built either within the bailey, as at Pembroke, or in Coucy-le-Château in France as the strongest point in the castle walls. Moreover, the square plan of the Norman keep was changed to a circular tower as were the other towers of the outer walls. This change probably results from the Crusades which brought western Europe into contact with such Byzantine round towers as Rumeli Hisar near Constantinople, built about 1100 by Alexius Comnenus. These Byzantine forts had already influenced the Saracens in their fortifications of Antioch, Nicaea, and Jerusalem that offered such formidable resistance to the crusaders.

Though not large, Coucy-le-Château (Fig. 4) of the early 13th century was an excellent example of the early Gothic castle. Walls whose angles were reinforced with round towers surrounded the irregular court and permitted the living quarters of the garrison to be built within and against the walls. Timber galleries might be added atop these walls and projecting from

their faces to permit the discharge of missiles on the heads of an attacking party. The keep or dungeon, 210 feet high, was the strongest feature and the point of last resort for the garrison if the bailey should be forced. Actually such castles were rarely taken except by treachery. Coucy never was, and its strength justified the arrogant motto of its lords: "I am not a king, nor a prince, nor a duke, nor even a count; I am the lord of Coucy."

Obviously if the homes of the nobility required such provision for defense, town dwellers also needed protection. Hence arose the walled city. If laid out afresh, and if built on level ground, the defenses were as regular as those of a Roman camp. Thus at Aigues-Mortes in Provence built by St. Louis in the 13th century, square walls with towers at regular intervals defended the town. The gates, also protected by towers, were in the center of each side. Indeed the only element of asymmetry, but a significant one, was the keep placed at one corner of the city walls. A larger and more famous example dating from several centuries is the city of Carcassonne. Here the terrain dictated irregularity in the walls which march up and down the slopes. The Middle Ages though not hostile to symmetry were always willing to abandon it when some requirement of either the site or the building suggested such a departure. The village of Villeneuve-lès-Avignon shows another, though less well-preserved, example. Parts of these old city walls are preserved in many places. Perhaps the best-known English example is Chester where quite an extensive walk on the walls is still possible.

In the second half of the 13th century, Edward I built a series of castles, many of them designed to hold in check the turbulence of the Welsh marches. Caerphilly Castle (1267-1277) in Glamorganshire, one of the earliest built in the Edwardian style, shows the new method of designing the castle with double walls—the inner ones enclosing the inner court or bailey, the second wall completely enveloping the first with space for an outer bailey between them. More than one gate made the task of investment by an enemy more difficult, and the presence of additional outworks still further hindered the attackers. Curtain walls punctuated with round towers suggested a derivation from Saracenic fortifications in Palestine. Conway Castle (1285-1287) in North Wales is another excellent example; long and narrow, its walls follow the contours of a high rock on the shore of the Conway River. Caernarvon Castle (1285-1322) with its hourglass form is on relatively level ground; but the double, or in part even triple, walls of Harlech Castle (1285-1290), Merionethshire, provide for outer, middle, and inner bailies. Naturally the strongest defenses of these castles were concentrated at their weakest points.

Complex as these large royal castles are, they do not provide the clearest illustrations either of what might be required normally for defense or still more of provision for the living requirements of the family and its household. For these purposes it is preferable to examine the small but very picturesque Bodiam Castle. In 1386 a license was granted to Sir Edward Dalyngrigge "that he may strengthen with a wall of stone and lime and crenellate and may construct and make into a castle his manor house of Bodiam, near the sea, in the county of Sussex, for the defense of

the adjacent country and the resistance of our enemies." This rectangular form of castle (Fig. 5) with its omission of the concentric walls of Edwardian castles came into vogue during the Hundred Years' War between France and England. A moat girdled the castle. The principal approach led over a wooden causeway from the side of the moat to a stone outwork, the barbican. A second bridge led in turn from the barbican to the main gate. In case of attack, these bridges, heavy enough for equestrian traffic, could be destroyed in succession; the second bridge would be demolished only if the barbican were captured or for any reason had to be abandoned. A small bridge for pedestrian traffic only crossed the moat to the postern gate at the back of the castle. Round towers defended the corners of Bodiam while square towers, paired around the main gate, marked the center of each side. Small windows, hardly more than loopholes, were strategically placed in the towers so that fire from them could be brought to bear either on the enemy across the moat, or along the walls if the attackers were bold enough to force their way across the water to the base of the wall. In fact the only window of any considerable size

FIG. 5. Bodiam Castle.

was the chapel window, high enough in the wall to be secure. The lower few feet of the walls were battered; that is, designed to slope outward. The purpose of this batter was less structural than military; if the base of the castle were approached, missiles dropped by the defenders from the top of the wall would be deflected outward by the batter against an attacking party.

Naturally the strongest defenses were reserved for the main gate. Here the towers were not only crenellated (battlemented); they were machicolated. The parapet was advanced beyond the plane of the wall on brackets, between which were openings to permit stones or perhaps boiling water to be dropped on the heads of an assaulting party. The notion of pouring molten lead on the enemy was more picturesque than practical in view of the value of metal in the Middle Ages. Loopholes or narrow slits would permit archers or crossbowmen to fire from comparative safety within. The last few feet of the causeway were made into a drawbridge that could be raised at night or when otherwise desirable. Finally a heavy timber grille or portcullis, reinforced with iron, slid down in front of the door, held in place by solid masonry on both sides.

Before the days of gunpowder, such a castle as Bodiam was practically impregnable, if the garrison remained loyal. To besiege such a castle involved keeping an army of sufficient strength in the field long enough to starve the defenders into submission. Since these castles were well provisioned and had their own sources of water within the walls—the kitchen tower at Bodiam had an ample well—a siege could be undertaken only at great cost. Arrows and crossbows would of course have no effect on these masonry walls, but the walls could be undermined. The presence of the moat, however, made that difficult and also hindered the approach up to the walls of movable towers from whose tops an attacking party might force an entrance. Battering rams and catapults that discharged heavy stones might in time batter down such walls, or incendiary arrows might ignite any inflammable materials within the castle; but since most of the interior, like the walls, was made of stone, the possibility of capture by assault was small indeed.

A welcome visitor, on the other hand, might ride across the bridges and through the barbican and the main gate. He would then find himself in the court, lined with rooms for the family and the household. To his left were the private chambers of the family including the castle chapel, small but adequate to the needs of the establishment. To his right and behind him were retainers' quarters and no doubt storage areas. Directly ahead he would see the door to a passage which in turn led to the postern; to the left was the great hall of the castle with the solar or withdrawing room of the lord and the ladies' bower at its further end; and to the right, an entrance to the pantry, the buttery, and the kitchen. These arrangements were almost standard in the later Middle Ages.

Though still the largest single room in the castle, the hall has dwindled in size relative to the space provided for other purposes when compared, for example, to the hall at Hedingham Castle. This smaller size reflected the change in living. No longer was it common to sleep in the hall; bedrooms were provided both for the family and the household. Although still used for meals, the custom of the family eating with the retainers was fading. Two quotations indicate the change. In 1235, Robert Grosseteste, bishop of Lincoln, wrote, "As much as ye may, eat ye in the hall afore your many (household) for that shall be to your profit and worship." But by the 1360's, Piers Plowman could say, "Dull is the hall each day in the week where neither lord nor lady likes to sit. Now has every kingdom a rule requiring one to eat by himself in a private parlor or in a chamber with a fireplace and to avoid the great hall that was made for men to eat in." Piers was kind enough to indicate a probable reason for the change. Although the hall usually had its fireplace, or a fire might be kindled in the center of its stone floor, its large size could not but have left it chilly and drafty. Nor could the rough retainers have been suitable companions at all times for the gentler members of the household. On the other hand, the courtyard solved the problem of adequate lighting for the hall and incidentally for the other rooms of the castle. If the outer wall for defensive reasons could have only a few small windows like those in Hedingham Castle, large windows could open into the court. Glass, how-

ever, remained a rare luxury until the 15th century or even later, and although oiled paper may have shut out some of the drafts, shutters were still the basic way of closing windows.

Next to the hall, the kitchen would be the largest room with its fireplaces perhaps capable of roasting an ox. Space was essential here in view of the number of mouths to be fed. In addition to the family, the household with its servants, its retainers, and its men-at-arms had to be provided for. Since Bodiam Castle required twenty garderobes (toilets), we may safely envision a household of very considerable numbers. These castles or manors also needed extensive storage space for provisions and activities through the year.

Many of the larger and more famous castles result from centuries of building and rebuilding. The royal castle at Windsor, for example, was begun by Edward III to replace an older castle which in part dated back to the time of William the Conqueror but has been much added to later. Kenilworth Castle, Warwickshire, celebrated by Sir Walter Scott, was begun about 1120; it later passed into royal hands, was given by Queen Elizabeth to her favorite, the earl of Leicester, and was subsequently destroyed in part under the Commonwealth for the sake of its building materials. One of the most imposing of them all was Warwick Castle, begun shortly after the Norman Conquest. Probably the most celebrated Irish castle is Blarney, now in ruins but still visited for sentimental reasons. In Scotland, Edinburgh Castle dominates the city; it was once a palace for the kings of Scotland.

The elements of military architecture in the Middle Ages and the life led within the castles did not differ essentially on the Continent from that in England. Thus the Château de Pierrefonds (1390-1400) was girdled first by a moat. Its approximately rectangular curtain wall linked together round towers at the corners, and in the middle of each wall, that serving as the entrance being larger and stronger than the others. The lower part of the walls was battered and their tops provided with machicolated parapets. Quarters for the garrison and retainers lined the courtyard as they had at Bodiam, although the owner, as befitted so high a noble as the duke of Valois, had a nearly independent residence near the gatehouse. Pierrefonds was dismantled in 1617 but restored during the 19th century by Viollet-le-Duc. The ruins of the Château Gailard, near Les Andelys, built by Richard Coeur de Lion are interesting historically. Though also in ruins, the Château de Gisors, its circular keep dating from about 1160, displays an early type. The keep was large enough to contain a chapel and was set within a broad bailey defended by a curtain wall with towers at intervals and with its principal gate heavily defended behind a barbican.

Owing partly to the weakness of the Holy Roman Empire during the later Middle Ages, the decentralization of feudalism was more pronounced in Germany than elsewhere. In consequence many castles were built by the robber barons of Germany to protect their lands or to levy tolls along the waterways and highways. Those along the Rhine from Bingen to Coblenz in particular are picturesque to a degree as they take advantage of the hilly ground. For example, Drachenfels, near Königswinter, was begun by Arnold, archbishop of Cologne, in 1147, and has

been much added to later. The 12th century castle of Schönburg with its four towers, near Oberwesel, is connected by legend with the Lorelei, while still another is Ehrenbreitstein where the Moselle joins the Rhine. Though many of these castles still exist, almost all have been drastically modified later.

The Moorish conquest of Spain and the centuries-long effort of the Christians to free the country brought into being a wealth of castles in the Iberian Peninsula. The place of religion in that war is suggested in the 11th century walled city of Avila with its 86 towers, where the fortresslike apse of the cathedral of later date forms a bastion. The mid-15th century Castillo de Fuensaldaña has a rectangular bailey with a great tower on one side capable of independent defense. The long struggle with the Moors left its mark on many Spanish castles as, for example, on the late 15th century Coca Castle where the Moorish influence is particularly strong. Architecturally, Coca with its immense batter of its lower walls, its multiple circular and polygonal towers and turrets, and its decorative band of brickwork around the top of its walls is magnificent, but Coca was so flimsy in construction as to give more the appearance than the reality of military strength. The Alcazar, Segovia, especially on the interior was also Moorish in style, while its tall and slender turrets at the angles, like minarets, make of it a picturesque "castle in Spain," though in fact the old fortress was destroyed in the 19th century and the present structure is purely modern.

The Renaissance Châteaux.—The medieval castle was almost immune to the weapons and methods of attack of its time. Although gunpowder was known in Europe at least as early as the 14th century, the changes it wrought in fortifications became evident only in the early 16th century. Under its impact, stone walls and towers lost much of their value. Moreover, with the growth of royal power, the intermittent warfare of feudalism disappeared so that defensibility was no longer essential to houses. Even so the influence of the castle was destined to linger on for centuries in French building.

The Italian Renaissance involved greater comfort, even luxury, in living than had existed under the feudal culture of the Middle Ages. Such virtual innovations as chairs, some of them upholstered, and forks as a normal item of tableware point to the growing sophistication of life. Up to the end of the 15th century, the peoples of northern Europe, including the French, remained unaware of these cultural changes. However, in 1494, Charles VIII undertook a military expedition into Italy in a futile attempt to establish his claim to the kingdom of Naples. Though unsuccessful, his venture introduced the culture of Italy to the French aristocracy; it was followed by the Italian invasions of Louis XII, and still later of Francis I. Thus French royalty and nobility were stimulated to try to transplant to France the forms of the Italian Renaissance. For this purpose, they invited Italian artists to Paris and Fontainebleau, and the designs of their châteaux begin to show Italianate elements.

The change could not take place over night. The Louis XII wing (1503) of the Château of Blois, though unfortified, remained predominantly Gothic. Its steep pitched roofs, its window forms, its traceried parapet at the top of the wall bespeak the force of medieval tradition, the

habits of design ingrained for centuries in the French builders. But around the doorway a few details of carving betray an awareness of Italian forms. Though only a few years later, the Francis I wing (1515–1519) at Blois had traveled further along this road. The Italianisms consist essentially of decorative shapes substituted for Gothic details, with but little change in the larger elements of design. Thus instead of Gothic pinnacles and a simple gable over the dormer windows, the new designers preferred candelabralike shapes and a tabernacle. In place of the Gothic tracery in the parapet, they used heraldic devices and the moldings of a classic cornice. Superposed pilasters created the vertical divisions of the wall. Canopied figures and Italian arabesques adorn the buttresslike supports of the spiral staircase, but the canopies like the dormers have been converted to the new forms. Significantly these rich Italianisms derive not from the serious examples of Renaissance architecture in Florence, but rather from the exuberant detail of such Lombard buildings as the façade of the Certosa at Pavia. Inevitably the French first encountered the north Italian style when they came down over the Alps into the plains of Lombardy, and it was the sumptuousness of this style that first impressed them. Aside from these Italian details, the major building forms continue from the French past. The steep pitched roof, the vertical divisions of the walls, the shape of the windows, and the towerlike projection of the stairway have lingered on. The spiral stairs of the medieval castle were placed in turrets that kept the stairs half inside and half outside the building. However, the stairs are larger here, and the lack of fortifications enables them to be open. So, too, the windows in the outer walls are larger. By this time, glass for windows had become common so that light could be provided without sacrificing warmth.

The Château of Chambord (1519–1538), being a more unified design, obviously shows the persistence in plan of French tradition even though its architect may have been the Italian Domenico Bernabei of Cortona, nicknamed Il Boccadoro. (Fig. 6). Aside from the Italian details carried out with a certain Rabelaisian exuberance, the new influence is apparent in the symmetry of the building. The Renaissance laid greater emphasis on symmetry than had the Gothic even to the extent at times of arranging the windows and doors to balance regardless of the interior, and perhaps of ignoring in their design irregularities of the site, although the latter was not a factor at Chambord.

But if these things point to the Renaissance, others perpetuate the traditions of the castle. The rectangular plan enclosed a court reminiscent of the castle inner baillies. The main unit

FIG. 6. Château of Chambord.

at Chambord in the center of the front projects into the court and corresponds to the medieval keep. This part, to be sure, has intersecting axial halls centering on the great spiral staircase now wholly inside of the building, but the long wings that enclose the court are still only one room and a corridor in width and in that are similar to the arrangement at Bodiam within its curtain walls. Towers linked together by other blocks of building compose the façade of Chambord. The derivation from the angle and intermediate towers and curtain walls of the medieval castle is obvious; in design both create an alternation of vertical and horizontal units, of strong accents set off by less emphasized portions. Such accents are almost never to be found among the Renaissance palaces of Italy. That these towers and links were conceived as semi-independent units is apparent in the arrangement of the visible roofs; conical roofs supporting turrets cover the towers while each link has its own gable roof hipped at both ends.

Like the exteriors, the interiors of the important rooms in the châteaux of the early 16th century combine medieval forms and Renaissance decoration. Thus the beams and joists that support the floors above are left visible to form the ceiling of the room below instead of being concealed by plaster or decorative paneling. The large fireplaces are still hooded, but the hood invited and received adornment in the form of Italian arabesques, heraldry, or cartouches.

During the reign of Francis I and his successor Henry II, many châteaux were built or rebuilt especially in the Touraine and the valley of the Loire. That of Chenonceaux, begun about 1518, was built on stone piers and arches spanning the river Cher. A smaller example is Azay-le-Rideau (1518-1524), where despite the symmetry of its façade and the architectural vocabulary of the Renaissance, the visible roofs designed as semi-independent units, the round turrets at each angle, and even the machicolations of medieval military architecture persist. The Château of Ancy-le-Franc (1538-1546) by the Italian architect Sebastiano Serlio exhibits a fuller appreciation of the properties of Renaissance architecture. The dormer windows, too, have so dwindled in size as to be unimportant, but the building still enclosed a court and retained the towerlike shapes at the corners.

The bitter struggle of the Huguenots and the Catholics during the successive reigns of the three sons of Henry II made the last half of the 16th century unproductive. Architecture began to revive under Henry IV of Navarre (r. 1589-1610) when the foundations for the later French supremacy in Europe were laid. During the 17th century, the last traces of the medieval castle faded away from the châteaux and palaces, centuries after those forms had lost the military reason for their existence. The palace of the Luxembourg (1615-1620) in Paris, in the style of Henry IV, was built after his death for his widow, Marie de Médicis. In her childhood she had known the newer parts of the Pitti Palace in Florence designed by Bartolomeo Ammanati, and to aid her architect, Salomon de Brosse, she had drawings of that edifice sent up from Florence. Hence, we find in the garden front of the Luxembourg rusticated orders applied to each of the three floors with some use of triangular and segmental pediments. On the other hand, pavilions with prominent roofs ter-

minate the façade and create vertical accents to contrast with the adjacent horizontal parts. The central bay of the garden front also projects and has its separate roof; its verticality is further accented by special emphasis given to its design. Thus the system of towers and curtain walls of the medieval fortress has been perpetuated for its rhythm in design. Although most parts of the Luxembourg are still only one room and a corridor in depth, at least the corner pavilions contain groups of four interconnecting rooms. Like the castle, the Luxembourg enclosed a square court, but a prophetic change has been made therein. The main part of the palace at the back of the court is three full stories in height, but the wings are only two stories, and the entrance front has been reduced to single story screen with hardly more function than to provide privacy.

The Château of Maisons-Laffitte (1642-1650) near Paris, designed by François Mansart, illustrates the next significant step. Although the plan resembles that of the Luxembourg, the mass of the building is quite different. The court has now vanished as an architectural element, but its location and extent are preserved in landscape design as a terrace with surrounding balustrades. That age-old feature will be retained henceforth for privacy only in the larger hotels within the cities. The elimination of the sense of confinement, the opportunity for unhampered circulation of air, perhaps for somewhat better lighting, and for uninterrupted views of the gardens speak of the changed conditions of life. But if the enclosed court is gone, the French tradition in other respects has not. The corner rooms of the first and second floors project at the ends of the façade and are emphasized in design by pilasters and special treatment of the windows. The central bay also is accented both by its richer architectural treatment and by its three-story height. Separate roofs cover each of these sections. Except for the vestiges of the court, Louis le Vau adopted the same scheme for the Château of Vaux-le-Vicomte (1657-1660) designed for Nicolas Fouquet, the minister of finance during the minority of Louis XIV. Here, however, the plan is two rooms in depth, and the oval salon projects from the façade as the central pavilion.

Finally in the immense palace at Versailles, the last traces of the medieval tradition almost vanish. To give here even the briefest history of Versailles is unnecessary, though we may observe that the palace as a whole, and particularly the suite of state apartments on the garden front, perfectly express that extreme centralization of government and of society in the court, its formality, pomp, and circumstance characteristic of the age of Louis XIV. These state apartments form a double file with the Hall of Mirrors occupying most of the main floor. In the center of the garden front, a free standing colonnade of six shafts at the second floor level rests on an arcaded ground story, while toward but not at the ends, similar four-columned pavilions are found. Here is the last trace of the medieval tower and curtain wall. The pavilions serve no function other than design; they do not correspond, as did their predecessors at Vaux-le-Vicomte, to separate rooms on the interior. Finally the pitch of the roof has been so reduced that it is no longer visible from the ground and therefore plays no aesthetic role in the building.

The medieval castle died with the feudal so-

ciety that brought it into being, but so firmly had it fixed its forms in the minds of the French builders that it took centuries for them to disappear. The picturesque appearance of the castles and their associations in song and story led at the time of the architectural revivals of the late 18th and 19th centuries to buildings modeled on them. Ardoch Castle, Dumbartonshire, is an example with its conscious asymmetry, its towers, and its battlements, but its basic arrangement, like the life it sheltered, was so foreign to the castles of the past that any resemblance to them derives more from sentiment than from architecture.

EVERARD M. UPJOHN,
Professor of Fine Arts, Columbia University.

CASTLETON, kàs"l-t'n, village, England, in Derbyshire, 9 miles northeast of Buxton. It is situated at the bottom of a rugged limestone eminence on which stands a small Norman keep built about 1176, part of Peveril Castle founded by William Peveril in 1068. The castle is celebrated in Scott's novel *Peveril of the Peak*.

CASTLETOWN, kàs"l-toun, town, Great Britain, former capital of the Isle of Man; on Castletown Bay; 9 miles southwest of Douglas. Castle Rushen, traditionally said to have been founded by Godred the Dane in 947, probably dates from the time of Magnus (1252–1265). Nearby is the Old House of Keys where parliamentary sessions were held until the seat of government was moved to Douglas in 1862. Just east of the town is King William's College, founded in 1643. Pop. (1951) 1,749.

CASTOR or **CASTOREUM**, an odorous substance obtained from the dried perineal glands and their secretion of the beaver. As a medicine, it was formerly used as a stimulant and an antispasmodic. Although it is now principally used by hunters as a scent to bait traps, it is also used as an ingredient in perfumes.

CASTOR AND POLLUX (the latter called by the Greeks Polydeuces), the mythological sons of Tyndareus, king of Lacedaemon, and Leda, or according to some, of Zeus and Leda.

Homer relates that Castor and Pollux were the sons of Tyndareus and that Helen was the daughter of Zeus.

According to one legend, Leda, whom Zeus visited in the form of a swan, brought forth two eggs; from one issued forth Pollux and Helen, from the other Castor and Clytemnestra. Pollux and Helen, being the offspring of Zeus, were immortal; but Castor and Clytemnestra, begotten by Tyndareus, were mortal. The two brothers were inseparable companions, equally brave and spirited, and attached to each other with the fondest affection. Castor was particularly skilled in the art of handling horses, and Pollux was masterful in boxing and wrestling.

The three chief events in their mythology are: (1) They were among the heroes of the Argonautic expedition in which they acquired divine honors. A terrible tempest had arisen on the voyage and all aboard called on the gods to be saved. Suddenly there appeared over the heads of Castor and Pollux two starlike meteors, and the tempest subsided. From this time they were the patron deities of mariners and received the name Dioscuri ("sons of Zeus"). The name Castor and Pollux was given to the lights which are often seen on the masts of ships during a storm, the electrical phenomena known as St. Elmo's Fire, or sometimes as Ledeian Lights. (2) After their return they rescued their sister Helen from the confinement in which Theseus had for some time held her. (3) They wooed the two daughters of Leucippus, Phoebe and Hilaeira, carried them off, and married them. Idas and Lynceus, nephews of Leucippus, pursued them, and in the resulting quarrel, Castor killed Lynceus but was himself killed by Idas. Pollux avenged his brother's death by slaying Idas. However, full of grief for Castor, Pollux asked Zeus either to take away his life or grant his brother immortality. Zeus granted his request by permitting them to reside alternately one day on earth and the other on Olympus. However, it is uncertain whether the brothers were always together or always separate in their passage between upper and lower worlds.

Temples and altars were consecrated to them. In great perils, especially in battles, the ancients believed that they frequently appeared to mortals as two youths in shining garments, on white steeds, with meteors over their heads. The cult of the Dioscuri was established in Rome in 484 B.C. in homage for their supposed assistance at the Battle of Lake Regillus.

CASTOR AND POLLUX, the two stars Alpha and Beta in the constellation Gemini. Castor is a famous double star, actually a sextuple system, since both its visual components and its faint distant physical companion are all spectroscopic binaries. The two bright visual components have magnitudes of +2.0 and +2.8 and revolve about their common center of gravity in a period of over 300 years. Both components are of the spectral class AO, and their combined mass is 5.5 times that of our Sun. The system is about 47 light years away from us.

CASTOR OIL (*Oleum Ricini*), an important vegetable oil from the seeds of the castor plant, otherwise known as castor bean and to botanists as *Ricinus communis* of the family of Euphorbiaceae. The plant grows in both tropical and semitropical regions. In the tropics it

attains heights of 30 to 40 feet, and as a hardy annual as far north as Oklahoma and Kansas it grows as high as 12 feet. The seeds contain from 35 to 55 per cent oil with an average yield of 49 per cent. At one time considerable crops of castor beans were harvested in the United States, but at present around 90 per cent of these seeds are imported, mainly from Brazil. During a peak year about 277 million pounds of imported seeds reached the United States, but less than 7 million pounds of oil were of foreign origin. A record production of the oil in this country was of the order of 125 million pounds.

Castor oil is one of the few vegetable oils that is composed mainly of a single glyceride, this being true only of olive and tung oils. In the case of castor oil, something like 86 per cent is the triglyceride of ricinoleic acid, with smaller amounts of the glycerides of oleic, linoleic, stearic, and dihydroxystearic acids. Ricinoleic acid is at the same time an unsaturated and a hydroxy acid, being 12 hydroxy-9-octadecenoic acid, $\text{CH}_3(\text{CH}_2)_7\text{CHOHCH}_2\text{CH}=\text{CH}(\text{CH}_2)_7\text{CO}_2\text{H}$.

The oil is very commonly cold-pressed from the crushed seeds to yield the highest grade of oil. The press cake is then extracted with solvents for a commercial grade. Solvent extraction of the meal without pressing has commonly put other undesirable components into the oil, but this difficulty is said to have been largely overcome in a more modern process. The press cake or pomace contains material toxic to men and animals, and is used as a fertilizer, being rich in nitrogen compounds.

The general public thinks of castor oil as a common medicinal, but this accounts for a relatively small quantity. Castor oil is still considered to be a valuable and efficient purgative.

Castor oil is subjected to a variety of treatments before it is industrially useful. When acted upon by 15 to 20 per cent of its own weight of concentrated sulphuric acid and gently warmed, it apparently produces sulphuric acid esters, since it is a hydroxy acid, rather than a sulphonic acid as the term "sulphonated castor oil" would imply. The product is known to industry as Turkey-red oil and is employed in the dyeing and finishing of textiles. When heated and exposed to a current of air or oxygen, polymerization takes place and the product is known as "blown castor oil." It is used as a plasticizer in lacquers, artificial leathers, and similar materials. Minor processes are hydrogenation to waxlike substances and saponification to produce materials that blend with other soaps to increase lathering.

The major treatment of castor oil is dehydration, that is, removal of the hydroxyl group and an adjoining hydrogen to form another double bond, which also doubles the degree of unsaturation. Partial dehydration results in an oil that is nondrying but which blends with mineral oils. It has been used in lubricating aircraft engines and is valuable in brake and hydraulic fluids. Most of the product is fully dehydrated by heating the raw oil to 250° to 300°C. under vacuum in the presence of catalysts. The hydroxyl group may be acetylated or reacted upon by free dehydrated ricinoleic acid to facilitate the transformation. The product is then a true drying oil and an excellent vehicle for paint pigments.

W. T. READ.

CASTOROIDES, kās-tō-roī'dēz, a giant ex-

tingent beaver of the Pleistocene epoch in North America. It was nearly as large as a black bear, had complex grinding teeth, and inhabited the cold swampy evergreen forests of the north. Its remains are found chiefly in peat bogs along with bones of mastodons.

CASTRAMENTATION, kās-trā-mē-tā'-shūn, an archaic term referring to that part of military science which deals with the principles and methods of laying out camps and the disposition of troops therein. Some of the main principles of the art of castramentation remain sound. These pertain to (1) the selection of camp sites with suitable physical characteristics (adequate water supply, terrain suitable for defense and maneuver, disease-free areas, available supplies of fuel); (2) the essential measures for protection of the camp (outposts and patrols to guard against surprise, protected flanks, prepared positions and defenses); (3) the disposition of the various elements and weapons of the troops so that they can quickly occupy their positions for battle and can properly support each other. And (4), the main feature of the art of castramentation, the one allotted the greatest space in dissertations on the art, dealt with the compact, methodical arrangement and precise alignment of troops and their facilities within the camp, principally to facilitate control and administration. Technological advances in weapons have outmoded this practice. Compact and methodically arranged camps as envisaged under the art of castramentation would today present themselves as inviting targets for long-range artillery fire and attack by aircraft, and losses sustained by such attacks would be enormous. Consequently, forces within range of an enemy are disposed in camps with a view to minimizing losses from artillery and air attacks. This requires dispersion of troops, concealment, and taking advantage of natural protection afforded by terrain features—factors that militate against orderly arrangement. The term castramentation is no longer in general military usage.

VINCENT JOSEPH ESPOSITO,
Colonel, United States Army; Professor of Military Art and Engineering, United States Military Academy.

CASTRATION, kās-trā'shūn, excision of one or both testicles (orchidectomy) or ovaries (oophorectomy). In the female, removal of the ovaries is sometimes referred to as female castration and in veterinary medicine it is known as spaying; the term castration usually refers to the male sex. The operation is employed to render horses and bullocks more docile especially in the presence of the opposite sex as well as to improve the breed. In most farm animals it serves to improve the quality of the meat, cattle and swine being mainly involved. In smaller animals such as dogs and cats the principal object of castration is to prevent wandering; in cats it is performed to make the tomcat acceptable as a house pet. Anesthesia is generally used for small animals, but in the case of colts and bullocks it is often unnecessary, the animals being controlled by a twitch, the stocks, or a maneuver known as casting, or by roping on the open range. There are two types of operation. In the first the scrotum is opened with a single stroke of a sharp knife, all coatings being severed. The testicle is then seized and removed by a metal emasculator

which crushes the spermatoc cord and lessens bleeding. In the case of unruly stallions anesthesia in the standing position is often advisable. In the second method the so-called bloodless operation is carried out with a special forceps which crushes the spermatoc cord through the skin. When the proper technique is employed results are said to be excellent, the testicle undergoing atrophy in about three months with loss of sexual propensities. It has the advantage of avoiding infection and is especially useful in castrating young rams where open operation has a high mortality. Colts are usually castrated at from six months to one year, and calves and pigs at from six weeks to six months. In older animals malignant disease of the genital organs may require the operation.

In human beings castration has a history extending over thousands of years. It was performed on Roman slaves to avoid procreation and has been common in all Oriental countries. Among the Chinese, up to the reign of the late empress dowager, the court swarmed with eunuchs who often occupied positions of trust and importance within the inner circle. An aspirant for such a place, where contact with women was unavoidable, was required to undergo the operation in a designated house where the operators were members of families practicing the art for centuries. In Italy, up to the close of the 18th century, boys were castrated young to preserve their high-pitched voices for the papal choir. The practice was forbidden by Pope Clement XIV about 1770. Castration in human beings is now looked on as a medical procedure indicated for malignant disease, advanced tuberculosis, undescended testicle, and as an elective procedure in operations for large hernias.

HAROLD WELLINGTON JONES, M.D.

CASTRATO, kās-tra'tō, a term used to designate the eunuchs who were much in demand as leading singers in the opera companies of the Continent and England during the 18th century. From the 16th through the 18th centuries the castration of singing boys was commonly practiced in Italy. In manhood the castrati possessed voices with the range and flexibility of sopranos and altos and with a lung capacity equal to or even greater than that of an adult man. The castrati were employed in the church choirs of Rome and elsewhere but they were most popular in opera. Most of the operas of Handel contained parts for male sopranos, and the fact that these parts cannot be performed satisfactorily by women is one of the reasons for the few performances of Handel's operas today. The most famous of the Italian castrati were Francesco Bernardi Senesino (c.1680–c.1750), Carlo Broschi, called Farinelli (1705–1782), Gaetano Majorano, called Caffarelli (1703–1783), and Giovanni Carestini (c.1705–after 1758). The part of Orfeo in Gluck's opera was one of the most famous roles written for a castrato.

CASTREN, kās'trān, Matthias Alexander, Finnish ethnologist and philologist: b. Tervola, Kemi, Finland; d. Helsingfors, May 7, 1852. He studied Greek and Latin at the University of Helsingfors and made various excursions into Finnish Lapland and Karelia tracing out the vari-

ous branches of the Finnish race and language. In 1851, returning from a journey to the Samoyeds, Castrén was appointed professor of Finnish and old Scandinavian at the University of Helsingfors. The following year, just before his death, he was promoted to the position of chancellor. Among his works are *Elementa grammatices Syrjænae*, *Elementa grammatices Tscheremissæ* (1844), *De affixis personalibus linguarum Altaicarum* (1850), and his translation of the *Kalevala*. He is considered the founder of Ural-Altaic philology.

CASTRES, kās'tr' (ancient CASTRA ALBIENSIS, kās'trā āl-bī-ēn'sī-ūm), city, France, in the department of Tarn; on the Agout River; 24 miles south of Albi. The town hall, a work of Jules Mansart, contains a Goya museum and has a garden laid out on the plan of the Tuilleries. Nearby is the Church of Saint-Benoit, a 17th century cathedral. There are large textile mills and furniture factories; other industries include metalworking, tanning, and brewing. The town, founded on the site of a Roman camp, arose around a Benedictine monastery which was built in 647. It was annexed to the crown in 1225 but surrendered to Simon IV de Montfort l'Amaury during his crusade against the Albigenes. In 1356 it was made a countship, and after a period of confiscation was again united with the crown in 1519. From 1317 to 1789 it was an episcopal see, throughout the religious wars having supported the Protestant cause. In 1629 the town surrendered to Louis XIII who ordered its fortification to be razed. Pop. (1946) 30,781.

CASTRIES, kās-trē', MARQUIS DE (CHARLES EUGÈNE GABRIEL DE LA CROIX), French marshal: b. Castries (Hérault), France, Feb. 25, 1727; d. Wolfenbüttel, Germany, Jan. 11, 1801. The son of a general officer, he was brought up by his uncle, the archbishop of Albi, and at 16 entered the army. He participated in all the wars in Flanders and Germany from 1743 to 1763. As minister of the navy from 1780 to 1787 he instituted many reforms, and it was during this tour that he was promoted marshal (1783). A royalist refugee in 1791, he was warmly welcomed by the duke of Brunswick, his one-time foe whom he had defeated in 1760 at the Battle of Closter-camp. From 1797 until his death he headed the cabinet of Louis XVIII at Blankenburg.

His son, ARMAND CHARLES AUGUSTIN DE LA CROIX (1756–1842), fought as general officer in the French army in the American War of Independence. He was a deputy at the session of the States General in 1789. An émigré, like his father, he returned to France after the restoration of the Bourbons, was promoted lieutenant general, and created a peer of France.

A descendant of these soldiers is Brig. Gen. CHRISTIAN DE CASTRIES (b. Paris, Aug. 11, 1902), whose heroic defense of Dien Bien Phu in north-west Vietnam in the spring of 1954, with about 10,000 French and French Union troops against from four to six times that number of Communist Vietminh besiegers, ranks as one of the most glorious feats of arms of the post-World War II period.

CASTRIES, kās-trē or kās'trēs (also called PORT CASTRIES), seaport, British West Indies, capital of Saint Lucia Island in the Windward Islands. The city shuttled between English and

French control but it has been English most of the time since the French settlement in 1650. It has an excellent landlocked harbor, and is a coaling station; during World War II it served as a naval base. Its exports include sugar cane, rum, molasses, cacao, fruits, and essential oils. Pop. (1946) 7,146.

CASTRIOTA, George. See SCANDERBEG.

CASTRO, kās'trō, Américo, Spanish scholar: b. Rio de Janeiro, Brazil, May 4, 1885. Educated at the universities of Granada, Paris, and Madrid, he was awarded his Ph.D. degree in 1913 by the last named. Appointed professor of the history of the Spanish language at Madrid in 1915, during the succeeding quarter century he spent many years abroad, as visiting professor at the University of Buenos Aires, Columbia University, and the universities of Berlin, Wisconsin, and Texas. In 1940 he received a regular faculty appointment to Princeton and is now emeritus. Among his more recent works on Spanish history and literature are *España en su historia* (1948), *Aspectos de vivir hispánico* (1949), *Ibero-americana* (1953), and *The Structure of Spanish History* (1953). He has also edited many scholarly editions of Spanish classic authors.

CASTRO, kās'trō, Cipriano, Venezuelan general and dictator: b. Capacho, Venezuela, Oct. 14, 1858; d. San Juan, Puerto Rico, Dec. 5, 1924. On May 23, 1899, he invaded Venezuela and led a successful revolt against President Ignacio Andrade, after which he declared himself "supreme military commander." On March 30, 1901 he became provisional president and served until elected president, Feb. 20, 1902. His administration was marked by despotism and numerous revolts. He involved his country in dangerous quarrels abroad, the most important of which were those with European creditor nations during 1902-1903, with the United States over confiscated property 1904-1908, and with Colombia and France in 1905. While on a trip to Europe he was deposed by a revolution led by Juan Vicente Gómez in 1908; he made several unsuccessful attempts to return.

CASTRO, Cristobal Vaca de, Spanish colonial administrator: b. 1492?; d. 1558. A member of the audiencia of Valladolid, he was sent to Peru by Charles V in 1540 to advise with Francisco Pizarro (q.v.) regarding conditions prevailing in the country. Learning on his arrival at Popayan of the assassination of Pizarro he assumed the reins of government and undertook suppression of the revolt headed by the younger Diego de Almagro (q.v.). He defeated Almagro at Chupas on Sept. 16, 1542, and had him executed at Cuzco for treason, and thereafter continued to administer the country until the arrival, early in 1544, of Blasco Nunez Vela, first viceroy of Peru. Imprisoned on suspicion of conspiring against the humanitarian "New Laws" passed at the instance of Bartolome de Las Casas (q.v.), he was sent back to Spain in disgrace; eventually he succeeded in clearing himself of all charges.

CASTRO, Ines or Inez de, Spanish noblewoman: b. 1320?; d. 1355. In 1354 she was married to Dom Pedro, son of Alfonso IV, king of Portugal, whose mistress she had already been

and whose wife, Constantia, had died in 1345. Because she was a member of the rival Castro family, Alfonso was persuaded that his son's union with her threatened his dynasty and resolved to put Ines to death. The first time that Pedro left Ines, the king hastened to Coimbra, where she was living in the convent of Santa Clara with her children. The arrival of Alfonso filled the unhappy lady with terror. She threw herself with her children at the king's feet, and begged for mercy. Alfonso was softened, but afterward gave his counsellors permission to commit the murder, and it was executed that very hour. Ines expired under the daggers of her enemies. She was buried in the convent where she was murdered. Pedro took arms against his father, but soon became reconciled to him. Two years later Alfonso died; the assassins had already left the kingdom and taken refuge with Pedro the Cruel of Castile. An exchange of fugitives was carried out. Of the three murderers of Ines, one escaped, but the other two were tortured in the presence of the young King Pedro at Santarem in 1360. Their hearts were torn out, their bodies burned, and their ashes scattered to the winds. Two years later, it is said, King Pedro at Cataneda declared on oath that after the death of Constantia he had obtained the consent of the Pope to his union with Ines, and had married her. The archbishop and Lobato confirmed the assertions of the king; and the Papal document to which the king referred was publicly exhibited. The king caused the body of Ines to be disinterred, and placed on a throne, adorned with the diadem and royal robes, and required all the nobility of the kingdom to approach and kiss the hem of her garment, rendering her when dead that homage which she had not received in her life. The body was interred at Alcobaça, where a splendid monument of white marble was erected, on which was placed her statue, with a royal crown on her head. The history of the unhappy Ines has furnished many poets of different nations with materials for tragedies, and the Portuguese muse has immortalized her through the pen of Luiz Vaz de Camões (q.v.), in whose celebrated *The Lusiad* the history of her love is one of the finest episodes.

CASTRO, João de, Portuguese navigator: b. Lisbon, Feb. 7, 1500; d. Ormuz, India, June 6, 1548. In 1538 he accompanied the viceroy Garcia de Neronha, his uncle, to India, as commander of a vessel, and in 1540 was in the expedition that explored the Red Sea, of which he made charts and records of considerable scientific value. In 1543 he was made commander of a fleet to rid the European seas of pirates, and two years later he was sent as governor to Portuguese India. He defeated Mahmud Shah III, king of Gujarat, relieved the city of Diu, and subjugated Malacca. King John III appointed him viceroy of Portuguese India in 1547. The *Roteiros* (logbooks) of his voyages, of considerable interest, were published in Lisbon (1833, 1843, 1872). A statue was erected in his honor. It stands over the gate of the principal entrance to Goa.

CASTRO, José María, Costa Rican statesman: b. San José, Sept. 1, 1818; d. 1893. He was educated at the University of León, Nicaragua, and held positions under the government of

Costa Rica. He was elected president for a two-year term in 1847. For his part in obtaining Costa Rica's independence from the Central American states in 1848, he received the official designation "Founder of the Republic of Costa Rica." He again served as president from 1866 to 1868.

CASTRO, kās'trô, town, Chile, Chiloé Province, on the east coast of Chiloé Island, 45 miles south of Ancud. The town, founded in 1567, was sacked by Dutch pirates in the 17th century and was destroyed by earthquake in 1837. Saw mills and textile factories flourish; lumber and potatoes are exported. Pop. (1940) 51,867.

CASTRO DEL RIO, kās'trô' thêl rē'ô, commune, Spain, in the province of Córdoba, 22 miles southeast of the city Córdoba, on a slope above the Guadajoz River. The more ancient portion is surrounded by ruined Moorish fortifications, flanked with towers and entered by one gate. The modern portion is outside the walls and extends along the foot of the hill on its north side. Most of the streets are wide and regular, lined with well-built houses and handsome public edifices. There is a 15th-century church as well as several convents, colleges, and schools. Lumbering is carried on and woolen cloth and earthenware are manufactured. There is considerable trade in agricultural produce. Pop. (1940) 15,916.

CASTRO-URDIALES, kās'trô-ôor-thyā'lās, seaport and municipality, Spain, in Santander Province, on the Bay of Biscay; 30 miles southeast of Santander. An ancient Roman colony, the town has a medieval castle and a parish church. Destroyed in 1813 by the French, it has grown rapidly since 1879 through the development of neighboring iron mines and increased railway facilities. Fishing and canning of fish, especially sardines in oil, are thriving industries. Iron is the largest export. Pop. (1940) 11,963.

CASTRO Y BELLVIS, kās'trô ê bêl-y'vês, **Guillén de**, Spanish playwright: b. Valencia, Spain, 1569; d. Madrid, Spain, July 28, 1631. Descended from an old aristocratic but impoverished family, Castro was captain of the coast guard of Valencia in 1593. After being governor of Scigliano in the Kingdom of Naples in 1607, he made Madrid his home and there gained the patronage of the Marquis of Peñafiel. He was married in 1595 and again in 1626.

His literary fame rests chiefly on his remarkable play in two parts, *Las Mocedades del Cid* (1599?), which, when adapted by Corneille, resulted in the first tragedy of the French classic theater. Castro was a friend of Lope de Vega in whose dramatic pattern he followed. He also seems to have been obsessed with the works of Cervantes as well as deriving inspiration from popular ballads. A remarkable example of the latter is his robust tragedy *El Conde Alarcos*. In another of his outstanding plays, *Los Mal Casados de Valencia*, he deals rather unsympathetically with the institution of marriage. Among the Spanish playwrights of the Golden Age, Guillén de Castro stands close in importance to the Big Three (Lope de Vega, Calderón, and Ruiz de Alarcón) for the dramatic force and vividness of his plays, his uncanny knowledge of human nature, and his mastery of style.

CASTROGIOVANNI, city, Sicily. See ENNA.

CASTROP-RAUXEL, kās'trôp-rouk'sêl, or **KASTRO-RAUXEL**, city, Germany, in North Rhine-Westphalia, formerly in Westphalia, on the Rhine-Herne and Dortmund-Ems canals. Manufactures include chemicals, textiles, liquor, and building materials. Through the incorporation of Castrop and neighboring communities including Rauxel, the new town was formed in 1926. Pop. (1950) 69,547.

CASTROREALE, kās-trô-râ-â'lâ, commune, Sicily, in Messina Province. About 20 miles southwest of Messina, in the Peloritani Mountains, it is in a grape- and olive-growing region. Its hot baths have made it a health resort. Pop. (1936) 9,044.

CASTRUCCIO CASTRACANI DEGLI ANTELMINELLI, kās-trôôt'chô kās-trâ-kâ'nê dâ'lyê ân-tâl-mê-nêl'lê, Italian soldier: b. Castuccio, near Lucca, Italy, March 29, 1281; d. Sept. 3, 1328. A Ghibelline leader and a *condottiere*, he served in Flanders, Lombardy, and central Italy; in 1316 he was elected lord of Lucca. He finally defeated the Florentines in 1325, the year in which Louis the Bavarian created him duke of Lucca. After capturing Pisa in 1327 he became imperial vicar.

CASTUERA, kās-too-â'râ, town, Spain, in the province of Badajoz in Estremadura. The inhabitants are engaged in weaving and making earthenware. Other industries include tanning, flour-milling, and extracting olive oil. Pop. (1940) 8,945.

CASUARINA, kâzh-û-â-rî'nâ, the single genus of the family Casuarinaceae, also known as beefwoods or she-oaks. There are about 30 species, native chiefly to Australia. They are jointed leafless trees or shrubs, having their male one-stamened flowers in whorled catkins, and their fruits in indurated cones. *C. equisetifolia* is the best-known species, and is much cultivated in Florida and California and in other rather tropical regions.

CASUISTRY, kâzh-û-îs-trî, the science or art of determining cases of conscience and the moral character of human acts; so called from *casus conscientiae*, a case of conscience. Wherever the question arises, Is such an act allowable by moral law? there is a case of conscience and matter of casuistry, and in deciding the question for himself, as everyone habitually does, everyone is a casuist. But in current usage a casuist is one who, skilled in the prescriptions of the divine moral law and its interpretation whether by lawgivers, moralists or theologians, studies either supposititious or actual cases of conscience and judges whether a given act, or even a given thought, is consistent with or in violation of moral law—for, unlike the civil lawgiver or the ministers of civil law, the casuist must determine the moral character of thoughts no less, or rather more, than of acts.

The professional casuist is inevitable in the system of the Catholic Church, where the minister of religion, in his capacity of *confessarius*, or confessor, must be the counsellor and director of penitents and resolve for them questions

of guilt or innocence, questions touching the obligation to restitution, for example of goods, or reparation of damage to a neighbor's reputation by slander; granting or withholding absolution according to the merits. For the minister of the sacrament of penance acts under Jesus Christ's commission, whose sins ye shall forgive, whose sins ye shall retain, shall be forgiven or retained; and to execute that commission the minister of the sacrament must decide for himself and the penitent the moral character of the acts.

The science or art of casuistry has doubtless been carried to extraordinary lengths; but though the questions which it treats are such as touch individually and most intimately daily and hourly the many millions of souls who resort to the confessional, the works of writers on casuistry, though voluminous, would count as a scant armful compared with only one part of the works contained in a law library—those which record the decisions of the civil courts. It is true also and inevitable that casuistry like law lore is often employed as a means of escaping from legal penalty or of quieting the sense of guilt. As there are lawyers who for a fee will defend any cause however defenseless morally, even to the extent of working injustice—loss of property, loss of reputation to the party opposite—so there are casuists who by their over-inclining to an indulgent interpretation of the divine moral law, release or cut the nerve of moral responsibility, administer an opiate to conscience.

Probabilism is the name given to the doctrine which declares to be lawful *in foro conscientiae* an act the moral correctness of which is affirmed by any moral theologian of weight (*doctor gravis*); or, as defined by Alfonso Maria de Liguori, a probable opinion is one which rests on a solid foundation (*fundamento gravi*) both of reason and of authority, so that it is able to move the assent (*flectere assensum*) of a prudent man, though with fear regarding the opposite. But a writer in a great encyclopaedia, who regards probabilism as "the most remarkable doctrine they (the casuists) promulgated—a doctrine which it is hard to believe that any one ever ventured to assert"—teaches that "according to probabilism" "any opinion which has been expressed by a 'grave doctor' may be looked upon as possessing a fair amount of probability, and may, therefore, be safely followed, even though one's conscience may insist upon the opposite course": the last clause is gratuitous and has no warrant in the teachings of Catholic moralists, who unanimously hold that an act done in defiance of conscience, even be it a plainly erroneous conscience, is a sin.

Viewed in the abstract, the rule of the probabilists is not an unreasonable one; it is acted upon daily by whoever, doubting his own judgment, asks counsel of others whom he regards as trustworthy advisers, even though they be not grave doctors (*graves doctores*). It is admitted that some of the probabilists, even the greatest of them, as Escobar, Suarez, Busembaum, did not always guard the doctrine against misconstruction, and gave occasion for views of moral obligation which were too lax: but the ecclesiastical censure has fallen upon such erroneous teachings, without discrediting for Catholic moralists the principle of probabilism. Let any other school of moral teaching set to itself

the same task which confronts the moral theologian of the Catholic Church, that is, to define with precision the moral character of every act, every thought, every imagination that has relation to the moral law, and it will be seen whether probabilism must not have a place in its system.

CASUS BELLI, the material grounds which justify (or are alleged by one of the parties concerned to justify) a declaration of war (q.v.). The *casus belli* is not seldom a very trifling one, and does not necessarily indicate the real *causa belli* or cause of the war.

CASWALL, Edward, English divine and poet: b. Yately, Hampshire, England, July 15, 1814; d. Edgbaston, near Birmingham, Jan. 2, 1878. A younger son of the vicar of Yately, he was educated at Marlborough and at Brasenose College, Oxford, where he graduated B.A. in 1836 and M.A. in 1838. After ordination he received the perpetual curacy of Stratford-sub-Castle, Wiltshire, in the diocese of his uncle, the bishop of Stratford. He resigned the living shortly before being received in the Roman Catholic Church in January 1847. His wife dying two years later, in March 1850 he joined the Oratory of St. Philip Neri at Edgbaston, near Birmingham, which had recently been founded by his friend Dr. John Henry Newman. Caswall had met the future cardinal at the house of Lord Shrewsbury; he always attributed his conversion to the Roman Catholic faith to Newman's brilliantly persuasive writings. On the eve of seceding from the established church Caswall published a collection of *Sermons on the Seen and Unseen* (1846). Subsequently he attained note as a sacred poet. He published a number of devotional works, most of them translated from the French, and was author of *Lyra Catholica, Containing All the Breviary and Missal Hymns with Others from Various Sources* (1849); *The Masque of Mary and Other Poems* (1858); and *A May Pageant and Other Poems* (1865).

CASWELL, Richard, American lawyer: b. Cecil County, Maryland, Aug. 3, 1729; d. Fayetteville, N. C., Nov. 20, 1789. He was a delegate to the Continental Congress, 1774–1776, president of the Provincial Congress which framed the state constitution, and a major general of the state militia during the Revolutionary War. He was elected the first governor of the state, 1776–1780, and re-elected 1785–1787, and was a delegate to the convention which framed the federal Constitution.

CAT, Christopher, English tavern keeper: fl. 1703–1733. Keeper of a London tavern in Shire Lane near Temple Bar, Christopher Cat is remembered as the entertainer from whom the Kit-Cat Club (q.v.) derived its name. Though some authorities date the origin of this political club from the year of the Revolution of 1688, the generally accepted version is that it was founded 15 years later, in 1703, by leading Whig Party members at Christopher Cat's tavern in Shire Lane. When Cat moved to the Fountain tavern in the Strand, the club accompanied him there, unwilling to forego his famous mutton pies. The club's summer meetings were held at Upper Flask tavern, on the edge of Hampstead Heath, and occasionally the members met at Jacob Tonnson's house at Barn Elms. A portrait of Cat by

Sir Godfrey Kneller was shown in London at the Portrait Exhibition of 1867.

CAT, a predatory mammal of the family Felidae (q.v.). All feline animals are cats in the broader sense, but in the more restricted usage the term refers to the smaller long-tailed members of the genus *Felis*. Of these there are some 20 or 25 species, widely distributed except for Australasia and the Polar regions. All are nocturnal, solitary, and highly predaceous in habit, usually catching their prey by creeping up and springing on it rather than by running it down. Otherwise they are very diverse in both habits and habitat, desert and grassland forms being by necessity strictly terrestrial, while most forest types spend much of their time in trees. There is great variation in color pattern, sometimes even within the same species, from a plain reddish, yellowish, or gray to a spotted or mottled pattern. The various species can be only very briefly enumerated.

Starting with the forms in the Eastern Hemisphere most closely related to the domestic cat, we have the common wildcat (*Felis catus*). Forms probably belonging to this species are widespread in Europe, Africa, and southwestern Asia, though in many regions, particularly western Europe, true wildcats are now rare. All domestic cats are presumably derived from this species, particularly from the Egyptian form. The large-eared desert cat (*F. margarita*) is a related form ranging from North Africa to Central Asia. The jungle cat (q.v.) or chaus is similar to but larger than *F. catus*. Another relative is the small black-footed cat (*F. nigripes*) of South Africa. Other related desert cats are the Chinese (*F. bieti*) and the manul (q.v.). All the above mentioned species have coat colors which are variants of the tabby domestic cat pattern. Most of the remaining Old World species are more definitely spotted. The serval (q.v.) is a long-legged African species. The leopard cat is a widespread east Asiatic form. A close relative, the rusty-spotted cat (*F. rubiginosa*) of southern India and Ceylon is the smallest known feline. The larger fishing cat (q.v.) is another allied form. Two related Malaysian species, the flatheaded cat (*F. planiceps*) and the Bornean bay cat (*F. badia*) have almost no trace of pattern, being solid red, brown, or gray, though with lighter underparts. Another southeastern Asiatic species is the marbled cat (*F. marmorata*), notable for its extremely long tail. The golden cats are exceedingly variable as to pattern, ranging from plain orange types to definitely spotted forms. A southeastern Asiatic (*F. temminckii*) and a west African species (*F. aurata*) are generally recognized.

Turning now to the Western Hemisphere, we find that all cats, in a restricted sense, are essentially tropical, though a few reach southern Texas. The animals called wildcats in North America are really lynxes (see *LYNX*). Most of the smaller long-tailed American cats are more or less spotted. Largest and most widely distributed of these is the ocelot (q.v.). The margay is a smaller widespread form. Several other poorly-known spotted forms are known from South America. Two better known ones, both confined to southern South America, are the guinea (*F. guinea*) and Geoffroy's cat (*F. geoffroyi*). Perhaps the most remarkable of the South American forms is the Andean cat (*F. jacobita*). Confined to the high mountains of Bolivia and Chile, it has an exceed-

ingly thick warm pelt, unlike the other species of that continent. The pampas cat (q.v.) is another form with a mottled or banded pattern. The widely-distributed jaguarundi (see *JAGUARUNDI*) is devoid of marking, being either solid red or solid gray.

Bibliography.—Hamilton, F., *The Wildcat of Europe* (London 1896); Mivart, St. George J., *The Cat* (New York 1892); Reighard, Jacob and Jennings, H. S., *Anatomy of the Cat* (New York 1935).

CAT, Domestic. Human civilization appears hardly ever to have existed without the presence of the cat. Oriental women discovered very early that without the cat the grain that was stored for winter use would be consumed by rodents. The ancients also engaged cats to help them catch birds used for food and birds which destroyed the fruit and grain. In California, also, cats were formerly used to hunt linnets, which were destroying the fruit crops. (See Helen Hunt Jackson's *The Hunter Cats of Connorloa*, 1879.) For centuries in China and Japan they have protected the silkworm cocoons from rats, which would eat the pupae.

Because of rodents, colonists everywhere recognized the important place of the cat in any program for future prosperity. In England cats are kept in government buildings as rodent destroyers, and certain sums are allotted for their maintenance. Fighting large rodents requires more than mere feline courage and ingenuity. It calls for strong, well-nourished bodies.

In some Oriental lands the cat is known by the onomatopoeic name of Mau, but few countries exist where a person would not be immediately understood if he referred to a cat as "cat." Palladius, the Roman writer and agriculturist of the late 4th century, is thought to have first applied to the domestic cat the word *catus*, which still remains its specific name. Several thousand years before Christ, however, the tame cat in Nubia was called *Kadis*. The Egyptians, with whom the cat became the most sacred of their many sacred animals, called the male cat *Kut* and the female *Kutta*, and the Turks, who greatly admired the animal, called it *Kedi*. Here we see the evolution of the words "cat" and "kitty" from *Kadis*, *Kutta*, and *Kedi*. The Greeks called the cat *Katta*. For generations the Swedes have summoned the cat by calling "Kitty, Kitty." In some other countries the call is "Puss, Puss."

The cat frequently uses sibilants, and the sound of a sibilant is instantly caught by its quick ear, which perhaps explains the use of the word "Puss," though some Orientalists believe that Puss derives from Pasht (Bast or Bastet), the ancient cat goddess of Egypt.

Origin and History of the House Cat.—Charles Darwin observed that the origin of all our domestic animals will probably remain forever vague. What he said nearly a century ago still stands, and we have not discovered the origin of the cat. A small animal of Madagascar called the fousa is regarded scientifically as a primitive form of cat, and it has been suspected that various small carnivores including cats originated from an animal called *Miacis*, which lived in the upper Eocene period of the earth's history about 40,000,000 years ago. In the Oligocene epoch, however, which followed the Eocene in geologic history, no intermediate forms between *Miacis* and cats have been unearthed. The latest conclusion, therefore, is that cats arose by the law of saltation (mutation) or sudden appearance. True

cats of various sizes inhabited the earth many millions of years before man. Fifty or sixty extant species are found in nearly all parts of the globe, and some fifty species are extinct.

The wildcats of Europe, like so many other animals, world over, are now nearly extinct because of human persecution, but they are easily tamed if captured when young.

Big cats of 30,000,000 years ago differed very little from big cats of today, though some were much larger than the tiger. North America is still inhabited by five groups of wildcats, some numbering many species. They range in size from the jaguar down to the ocelot. The jaguar is the fiercest American wildcat; the puma or mountain lion, which is not a man-eater, would be friendly to man if permitted. The smaller jaguarundi, lynx, and ocelot have all been maintained as household pets and have usually proved one-man animals. American wildcats in general are larger than the house cat and no small feline related to house cats originated in the Western Hemisphere, where the wildcats are natural enemies and destroyers of domestic cats and no mating between the two has ever been recorded.

The domestic cat, however, will mate with Asiatic, African, and European wildcats, and it is naturally deduced that these species figured among its forebears. In fact, American domestic cats are known to owe their ancestry to an admixture of Asiatic and African tame cats with the several varieties of wildcats formerly common in Europe. Due to its wide distribution and small size, the house cat is necessarily the best-known member of the family of cats, great and small.

All house cats are of but one genus and one species, *Felis catus*. There are no subspecies or varieties of domestic cats, but many breeds or races (called also variations and variants) occur within the species, the same as among human beings.

Even the earliest domestication of the small cat is shrouded in mystery. When the Egyptians obtained the animal from Nubia about 5,000 years ago, it was already domesticated in India and China, and Indian scholars claim that wildcats, including the jungle cat and desert cat, were first domesticated in their country. The Egyptians tamed several breeds of native cats such as the Kaffir cat (*Felis caffra*), which bears a strong resemblance to our domestic cats in stripes, ringed tail, and letter M in the forehead. The jew's-harp in the forehead of many house cats appears to derive from Temminck's golden cat (*F. temminckii*), which ranges from India north through China and south through Indonesia.

Phoenicians are credited with having taken Egyptian cats to many foreign ports, and other seafaring men from the most ancient times are believed to have carried various breeds of cats on their voyages and introduced them here and there throughout the East. The domestic cat was well known in Crete by 1500 B.C. and is believed to have reached Greece later.

The origin of long-haired cats, which are found principally in China, Angora, Burma, Afghanistan, and Russia, is equally vague. There are few in Persia. For many years the Persian cat has come from Afghanistan, and it is commonly held that its main ancestor was Pallas' Tibetan cat (*F. manul*) of Central Asia. Strong evidence exists that long-haired cats were taken from China into Siberia and from Afghanistan into India, but Reginald I. Pocock, great British authority on

cats, believed that those which reached England had long been harbored in countries situated near the eastern end of the Mediterranean.

General Facts About Cats.—*Temperament.*—

Cats are temperamental animals, playful and graceful, but reserved, timid, and high strung. They are independent and intractable and cannot endure restraint. Their affection for human beings and for occasional members of their own species is keen. They often select some member of the household as a favorite, and mother cats also have favorites among their offspring. They show emotion and have been known to weep. Their sense of companionship is strong, and they will protect unrelated animals and birds of the household yet prey upon the same species elsewhere. They jealously guard proprietary rights such as their own mouse holes and home comforts, and may suffer greatly if, once ensconced in a household, another pet is introduced. Under such circumstances many have died of grief. They are grateful for small favors. Curiosity is a dominant trait and they will help open packages and investigate every detail of unfamiliar surroundings. They can look a person steadily in the eye. They enjoy resting off the ground but, like many other animals, cannot bear to discover another creature of their species perched above them in the open. Cats have a sense of humor, and both cats and kittens smile. They dream during sleep and some observers think they are also given to daydreaming. Their patience and power of concentration are extraordinary, and their memory excellent. After an absence of six years a cat has been known to greet the members of the family, then go directly to its favorite napping place. A highly intelligent animal, it often exhibits remarkable reasoning powers. Its wits become sharpened when it is talked to, and it learns the meaning of a number of words. Cats dislike noise, though some enjoy music, instrumental or vocal, while others cannot tolerate it. The contented cat rests with forepaws folded beneath its breast. Like most male animals, tomcats fight, and are notoriously vocal about it. Cats teach themselves tricks and perform them happily on request, but cannot be coerced, and when exhibited in trick performances under compulsion, cruel usage may be suspected. As Rudyard Kipling said long ago, the cat "walks by himself." Love and gentleness effect much; rough treatment, nothing.

Physical Characters.—Some house cats appear to carry the blood of the fishing cats of the Orient and engage in fishing, also swimming, in salt or fresh water. Most cats prefer to keep their fur dry, however. Cats grow gray with age, and in the Siamese breed the mask becomes pale from grief or sickness. Like other members of the family Felidae, they purr. They possess mechanical ingenuity, and being natural imitators, can open doors and windows and ring bells. Many cats possess the homing instinct in a surprising degree, some having found their way home over hundreds of miles and with rivers to cross. All do not possess this instinct, however, and some are easily lost. They should be provided with a collar of leather or elastic, with name tag attached, bearing the owner's name and address. The voice of the cat, which covers two full octaves, presents a variety of expressions, its inflections conveying the meaning. The language consists of both consonants and vowels and covers a wide range of emotions. Cats spit, mew, hiss, growl, screech, and caterwaul. The body is lithe, with a loose

skin, and a flexible spine which permits the rearing of the back, and it is equipped with more than 500 voluntary muscles, over 230 bones, and about 50 vertebrae. The average length is about 28 inches in the male and 21 in the female, exclusive of tail. There is no breed of dwarf cats. The male cat averages a weight of from nine to seventeen pounds, the female six to ten pounds. Cats weighing 25 pounds have been exhibited at cat shows. The tail varies, and may be long, short, kinked, bobbed, curled, double, or missing. Kink-tailed cats, also tailless and stump-tailed cats, are common in Asia. The ears also vary, and a cat may have stiff ears, lop ears, or tufted ears. The animal is digitigrade, and the fore feet have five toes, the hind feet four. A cat with double paws, or one having a total of 24 toes, is not unique. The feet are adapted to climbing, and only the Manx cat can run long and rapidly. The claws are shed throughout the year, and the cat works off the loose bits of the front ones by scratching on soft wood, those of the hind claws being removed with the teeth. Cats do not sharpen their claws. They appreciate a scratching post covered with carpet and containing a little catnip. The milk dentition consists of 24 teeth, the adult teeth numbering 30. The coat is shed in summer. The cat's pupils contract by day and expand at night. It cannot see in total darkness, but sees best in a dim light. Its eyes vary in color and both eyes are not always the same color. In semidarkness they reflect rays of light of different colors, depending on the color of the tapetum or inner layer of cells of the eye, which may be blue, gold, pink, or green. The cat is one of several species of animals, including wildcats such as ocelots and lynxes, which, in falling, turn and land on their feet. This ability is believed to be due to the structure of the semicircular ear canals. It has nothing to do with the tail, for tailless Manx cats make the turn in falling quite as successfully as cats with truncated tails or long tails. Cats ordinarily need only two meals a day, with water to drink at all times; but during the breeding season both sexes require three or four meals a day. If the female's diet is lacking in minerals, such as a little salt or bone meal in her food, she may devour her young, like a dog or a pig. Cats are not wholly carnivorous, and while meat and fish constitute their main fare, they like grass, catnip, and vegetables, and many favor fruit juices and fruit such as cantaloupe. Like most other animals and also many birds, they are fond of milk, and other dairy products are also enjoyed. A sick cat will usually accept alcoholic liquors.

Reproduction.—The period of gestation varies, but averages 63 days. Females come in season for three to fifteen days about three times a year, and if unchecked will be nursing or carrying kittens almost continuously. Males are held best for breeding when from three to fourteen years old, females when from two to eight years, but fine kittens have been produced by much older cats. Some have bred when more than 25 years old. Fancy cats are customarily restricted to one or two litters a year, too many kittens being considered detrimental to their quality. The cat's fecundity is proverbial, and to prevent the cruelty of abandonment it is hoped that movements afoot throughout the United States for spaying female cats as well as neutering males not desired to perpetuate the breed will prove effective. The young commonly number four or five in a litter, though the Siamese cat may produce eight or nine.

Siamese kittens may be born with eyes open, and in this breed, unlike others, males can be trusted with the young until they mature. Kittens of other breeds are born deaf and blind, but with a sense of touch. In three days they can smell and taste, after which hearing is established and finally sight. Kittens purr and hiss before their eyes are open. Identical twins are born among cats as among other animals and are called also one-egg twins because they develop in the same embryonic sac and not in separate sacs like their siblings. Unlike fraternal twins, they are always of the same sex, weight, temperament, and color in coat and eyes. Female cats will suckle unrelated animals such as skunks, squirrels, rats, and even puppies—their willingness to do so depending largely on their supply of milk. In all species of Felidae, great and small, the mother carries her young in her mouth. Monstrosities also occur among cats. Two or more kittens may be joined together, a kitten may be born with eight legs, two heads, or two tails, or may lack some of its appendages.

Longevity.—The natural life span of the cat is reckoned as 14 years, but many reach 18 or 19, and some live much longer. Reliable records show that some have lived for more than 30 years.

Superstitions.—The common superstitions—that black cats have more electricity in their fur than those of other colors, that cats are occult, that those of one color are lucky and of another color unlucky, that they care more for places than for people, and that female cats mate with unrelated animals such as raccoons, skunks, and rabbits—are entirely without foundation.

Some Breeds of Cats in North America.—North America has been made familiar from time to time with a majority of the more than 30 breeds of domestic cats of Europe and the East. House cats are divided first into short-haired and long-haired groups, next into American short-haired and foreign short-haired cats, and finally into individual breeds.

Short-haired Cats.—We know that the striped tabby or tiger cat figured among the earliest ancestors of domestic short-haired cats, because animals gone wild commonly revert to type, and when cats go wild they assume the gray body color and black markings of the striped tabby. The tiger cat has been propagated in Europe for four known centuries. Its gray ground color is offset by black vertical stripes extending back from the shoulder, and one heavy black stripe runs down the back from the head to the tip of the tail, which is ringed with black. The two transverse lines characteristic of wildcats appear on either cheek, also the letter M in the forehead, with bars on the legs and chest (called bracelets and necklaces). The eyes are green or hazel. This cat is now exhibited only as a household pet.

The Brown or Blotched Tabby and Its Sub-breeds.—The brown tabby is believed to have arisen in Europe, west of the Mediterranean, more than two centuries ago. Through selective breeding the original gray body and green eyes have been replaced by a ground color of brown and orange eyes. The sides are marked with broad swirls or blotches, and a butterfly appears on each shoulder, dividing the lines of the head from those of the back, which consist of three parallel black stripes running from neck to tail. Sub-breeds are the silver tabby with green or hazel eyes, and the red tabby with orange eyes. Produced by artificial selection, their colors replace the original gray or brown ground color, with black

stripes in the silver tabby, but stripes of only a deeper orange than the body color in the red tabby. The letter M or a jew's-harp may appear in the forehead of the tabbies. Tortoise-shell cats, silvers, smoke cats, and cats of solid color evolved later. Tortoise-shells are much more rare than tortoise-shell-and-white cats, white being a dominant color in cats and difficult to outbreed. The true tortoise-shell carries no white in its coat and no tabby markings, but only red, black and yellow in distinct patches. The nose is half black and half orange, the eyes orange or copper. The tortoise-shell-and-white cat, commonly called tortoise-shell, has the same colors with white added. Males of these two cats are uncommon and apt to be infertile. A six-color male tortoise-shell-and-white cat was exhibited in California in 1946 in which the additional colors were blue and gray. A three-color male tortoise-shell was exhibited twice in Texas during the winter of 1952-1953. A fertile tortoise-shell male crossed with a black female has been known to sire a male tortoise-shell. Short-haired American cats of solid color are white with blue or yellow eyes, black, blue, red, orange, and cream or fawn, all having orange eyes. Foreign short-haired cats are the Siamese, Manx, Burmese, Abyssinian, and Russian blue. The best-known Siamese is the seal-point, first imported into the United States about 1895. The pale fawn-colored body carries brown points, that is, dark brown feet, tips of ears, tail and muzzle. The young are born white and develop the adult colors within a year. Other Siamese cats are the chocolate-point and blue-point, having these different points but the same ground color as the seal-point, and the red-point, which was produced in 1950 at the Jackson Memorial Laboratory in Bar Harbor, Maine. It is yellow with orange points. All Siamese cats have blue eyes. How the tailless Manx cat arrived on the Isle of Man is a question which the foremost scientists of Britain cannot answer. The Manx does not always breed true, and after many generations of careful selection kittens with long tails, bob tails and screw tails appear; but only a completely tailless cat, with a dimple where the tail begins in other cats, can be sold as a perfect specimen. It leaps and runs, but does not hop, has a double coat of varying color, and its hind quarters are slightly higher than those of other cats. The Burmese cat has a short, glossy, walnut-brown coat which is lighter on the chest and abdomen, with darker brown points, and its eyes range from golden turquoise to yellow. The tail may be slightly kinked near its extremity. The Abyssinian ticked cat has been common in the East since about a thousand years after the Pharaohs and is believed to have arisen as a mutation of the striped tabby by the breaking up of the stripes into spots and the spots into ticking, which also appears at times in ordinary tabbies. The coat sometimes shows the ancient tabby markings, but is usually gray or brown above and rufous beneath, each hair being tipped with dark brown, which produces the ticking. The nose is dark red edged with black, and the eyes green, hazel, or yellow. The ears are tipped and edged with black. Heels, paws, and toe pads are also black, and a black stripe extends down the back to the end of the tail. The Russian blue cat is the handsomest of the short-haired blues, a large and muscular animal with the heavy coat of cats accustomed to cold climates.

Long-haired Cats.—The Angora was the first long-haired cat in America and was brought from

Angora in Turkey to Maine and Massachusetts by mariners a century or more ago. In these states the pure breed may still be found. It is called the Maine cat, also coon cat, and at the earliest American cat shows it ranked above the Persians, which were first imported about 60 years ago; but the Angora breed no longer enjoys a show standing, having been completely eclipsed by the Persian cat.

The Angora is found in various colors and its fur is long and glossy with a bushy tail and Queen Elizabeth ruff. The ears and body are long and the face pointed. The Persian cat has a less glossy coat, more compact body (called "cobby"), smaller ears, a rounder head, and shorter legs than the Angora, but with ruff and bushy tail. Among the silver Persians of several breeds, including the chinchilla, all have green eyes. Smoke Persians have a silvery-white undercoat shading to smoke, a black top coat, with silver frill and ear tufts, and orange eyes. Brown tabbies, red tabbies, and silver tabbies, as well as cats of solid color, occur in the Persian group, also tortoise-shells, occasional blue torties in which the blue replaces black, blue cream (a two-color cat as the name denotes), and peke-faced cats which are red, orange, and red tabby, with indented noses and orange eyes.

Fashions change in cats, as illustrated in the case of the Angora, and the overwhelming popularity of the blue Persian and seal-point Siamese may give way to other breeds at any time.

A still rare breed is the Siamese-Persian, to produce which seal-point Siamese in Europe and America have been crossed with white, black, or silver Persians. The cat, as its name indicates, is a new breed of long-haired cat with Siamese markings. About five years are required to produce a new breed of cat and the work calls for ample space and the supervision of a geneticist.

Albino cats occur about once in 25 years, but do not establish themselves. A pair of albinos appeared in a litter of Siamese seal-point cats in California in 1947, an occurrence which may be repeated, as cats with blue eyes, such as Siamese and some white cats, are semialbinos.

Cat Shows.—Minor cat shows apparently began in New England with the Angora cat, but the world's first major show was inaugurated by Harrison W. Weir at the Crystal Palace in London in 1871. More minor shows followed in America and finally the first annual exhibition of cats took place at Madison Square Garden in New York City in May, 1895, with 176 entries. Ribbons, collars, cash, and other prizes were awarded. The most valuable cats exhibited were two short-haired tabbies, a male and a neuter, each priced at \$1,000, and the cat adjudged Best in the Show was a short-haired neuter with seven toes (color either red or blue). Two Angoras, a male and a neuter, were adjudged Best Long-Haired Cats in the Show. Though the earliest shows were conducted by men, women took them over and remain the principal exhibitors. Cat shows are held in various parts of Europe and America, winter being the preferred season, when the cats' coats are at their best. Veterinarians are present to guard against contagious diseases, and a committee is appointed to feed the exhibits. Valuations vary with the times, cats having been sold in America for from one dollar to \$2,000.

The Cat Fanciers' Association, Cat Fanciers' Federation, and American Cat Association carry a total of more than 130 member clubs dedicated to the breeding and showing of all breeds of cats.

The Siamese Cat Society of America, oldest Siamese club, is an independent organization. Stud books and registration blanks are issued by these societies, that cats and kittens to be sold may be properly recorded and pedigrees established. Registering a cat's name prevents its duplication. A cat is considered an adult when nine months old and kittens for showing must be between four and eight months of age.

Show classes cover kittens, neuters and spays, cats that have not won a blue ribbon, and various others. Ribbons in their order of importance are blue, red, yellow, and green. A Grand Champion and Grand Champion of Opposite Sex receive a purple ribbon or rosette. A white ribbon is awarded as a special prize. A blue ribbon counts for a certain number of points (usually ten) toward a championship, and prize winners in the championship class compete for Best Champion in the Show, the winner receiving points toward a grand championship. There are standards for long-haired cats, others for short-haired cats, each set of standards covering a total of 100 points, which include a specified number for coat and eye color, shape of head and body, condition of coat, etc. Each show is presided over by a competent judge. Breeders have effected remarkable improvements by taking advantage of spontaneous variations in color of body and eyes, shape of body, musculature, size of ears, and other characters. The cross eyes and kinked tail of the Siamese cat have been largely bred out, also the white "locket" which naturally appears at the throat of many cats and is considered a fault except in the Manx breed. America boasts of a magazine devoted to cats, also a National Cat Week, and besides the numerous clubs dedicated to breeding and showing cats, other associations exist solely for the protection of the cat, such as the Holyoke Kitten Club (Massachusetts), Allied Cat Lovers (Minnesota), and Federated Group (California).

The cat is the most difficult of all animals to draw, and prior to the invention of the camera few artists, other than Henriette Ronner, succeeded in portraying the animal with any degree of accuracy. The work of some modern artists such as Peggy Bacon, Clare Turlay Newberry, Wanda Gag and Zhenya Gay, surpass almost all delineations of the cat attempted before the arrival of the camera. The most famous cat cartoons are those of Louis Wain, and the most celebrated photographers of cats are Ylla and Walter Chandoha.

Zoologist; Former Chief Aquarist of the New
York Aquarium.

CAT ISLAND, one of the Bahama Islands, in the Atlantic Ocean, northwest of San Salvador and southeast of Eleuthera Island. About 50 miles long and about 3 miles wide with an area of 160 square miles, it is the most fertile island of the archipelago, producing coconuts, sisal, sweet potatoes, pineapples, and bananas; forest trees include pine, cedar, and mahogany. This island was long identified with the Guanahani or San Salvador on which Columbus landed on Oct. 12, 1492. The

honor has been conceded to Watling Island. Pop. (1943) 3,870.

CAT OWL, a name applied in America to various owls, especially the great horned owl (*Bubo virginianus*), whose round face and earlike horns or feather tufts produce a feline visage.

CAT SHARK, the members of the Scyliorhinidae, a group of sharks characterized by having at least half the base of the first dorsal behind the origin of the pelvics; a non-lunate caudal and no connecting grooves between mouth and nostrils.

CATACHRESIS, kăt-ă-krě'sis, the metaphorical employment of a word to designate some object for which the language lacks a specific term—the *arms* of a chair. Catachresis also signifies the use of a word which does not correctly express the intended meaning, as when *aggravate* is used in the sense of *provoke*, or *infer* where the meaning is *imply*.

CATACOMBS. The word catacomb comes from the medieval Latin term *catacumba*, which itself derives from the Greek κατά (below) and κύβη (a hollow or declivity). It was first used to designate an area on the Appian Way some three miles south of Rome, where now stands the church of St. Sebastian above a subterranean catacomb of the same name. Modern excavations beneath this church, which had been originally dedicated to the apostles by Constantine, the first Christian emperor, revealed a steep ravine honeycombed with tombs where, according to early tradition, the bodies of Sts. Peter and Paul had at one time reposed. Because of its association with the two apostles, this cemetery, which was properly indicated as *ad catacumbas*, that is, "at the hollows," became a place of pilgrimage and remained accessible until the 9th century, when it and all the other underground burial places of the early Christians were forgotten. Its name, however, survived, and was eventually applied to all subterranean cemeteries of similar nature, whether pagan or Christian. In modern usage, therefore, the term has been loosely and improperly extended to cover every sort of underground area in which burials have been made or human bones deposited, from the rock-cut tombs of the ancient Egyptians, Persians, and Syrians, and the natural caves used as catacombs in Sicily, to the abandoned quarries similarly employed at Naples and Paris. Although many of these are romantically impressive and often of considerable historical and archaeological interest, they lie outside the bounds of our discussion, since the majority were used for pagan burials, whereas the others, originally quarries, were later adapted to sepulchral use both by pagans and Christians. Hence the catacombs here considered are those vast complexes of subterranean galleries, passages, stairways, and chambers excavated by the early Christians in the outskirts of ancient cities to serve specifically as cemeteries, that is, as resting places for the dead.

Although by far the most famous and extensive Christian catacombs are those of Rome, similar underground cemeteries exist throughout the Mediterranean area, scattered from Italy to Malta, Alexandria in Egypt, and Sousse in Tunisia. The Roman catacombs, however, surpass all others in religious, historic, and artistic interest, not only because they bear witness to the primary importance

of the vital Christian community which created them at the capital of the pagan Roman Empire, but also because they provide our earliest information, after the Gospels themselves, on the beliefs, the doctrines, and even the mode of life of the first organized Christian groups.

The Roman Catacombs.—Abandoned and forgotten in the 9th century, the Roman catacombs were rediscovered by isolated pilgrims and scholars of the Renaissance, although not until 1593, when Antonio Bosio (1576–1629) began his life-long studies and researches, did they receive more than cursory examination. With the posthumous publication in 1632 of his famous *Roma sotterranea cristiana* he laid the foundations for the study of what later became one of the most important branches of modern archaeology, that dealing with the antiquities of the early Christian church. Unfortunately, however, the course marked by Bosio was not followed consistently during the two subsequent centuries, so that the Roman catacombs were again neglected and even suffered greatly from vandalism and pillage. This trend was checked in the 19th century, and the modern era of intensive and truly scientific investigation was inaugurated by the great Italian scholar Giovanni Battista de Rossi (1822–1894), who in 1842 began a series of remarkable discoveries which, continued throughout his life and described in his monumental publications, rank him as the father of this branch of modern scholarship. Thanks largely to the inspiration of de Rossi, his researches were advanced still further by a number of brilliant contemporaries and successors, whose most important publications are listed at the close of this article. As a result of these continuing researches, no less than 50 separate catacombs, cut in the sub-soil to serve as places of burial, are now known to exist in the environs of Rome. The total length of their subterranean galleries approximates 550 miles and the total excavated area slightly less than 620 acres, providing accommodation in their labyrinthine depths for an estimated 6 million bodies.

Location.—The scattered disposition and individual peculiarities of the 50 or more distinct and unconnected catacombs which surround the city were determined by geological factors. Beneath the surface humus of the campagna there exists no uniform stratification, but instead varied masses of sedimentary and volcanic formations, the latter comprising large deposits of volcanic sand called *pozzolana*, reefs and ledges of hard red *tufa*, and isolated strata of the softer granular *tufa*. Of these three materials, the first two were highly valued for building, and had therefore been extensively mined and quarried by the ancient Romans; the strata of granular *tufa*, on the other hand, being too soft for structural uses, had remained undisturbed, and became the medium preferred by the Christians for the excavation of their catacombs. The reasons for this choice are obvious. In attacking the softer strata the Christians were sure of not infringing on the cuttings of their pagan persecutors; while the rock itself, though soft enough to be cut with pick and shovel, was sufficiently resistant to make possible the hollowing-out of the characteristic grave niches in the lateral walls of the passages without fear that the walls themselves would collapse. The *tufa* had, finally, the great advantage of being porous and, therefore, hygienic; it absorbed infiltrating moisture, a valuable characteristic for areas destined to receive so many corpses. Since the Christians

sought out by preference the underground masses of granular *tufa* for their sepulchral galleries, it is easy to understand why the various catacombs of Rome are not only distinct but also widely scattered. The geologic strata themselves were not continuous, and their own sporadic occurrence determined the isolation and wide distribution of the majority of Christian catacombs in the environs of Rome.

History.—The history of these cities of the dead spans a period of 800 years, beginning with the coming of Christianity to Rome at the middle of the 1st century and ending in the 9th, after many thousands of bones of the early martyrs had been stolen to serve as wonder-working relics enshrined beneath the altars of churches throughout Christendom. This long span of centuries divides into two main periods. The first was the era of persecution, from the martyrdom of Sts. Peter and Paul to the Edict of Milan in 313, when Constantine gave official recognition to the new religion. During this phase the catacombs were excavated and adorned to serve as resting places for those who died in the Lord. During the second period, which began with the triumph of Christianity, the catacombs declined as burial places and gradually assumed the role of hallowed shrines to which pilgrims came to venerate the relics of the saints. Eventually, however, with the violation of the sanctuaries by the removal of their relics, the old tombs gradually lost their power of attraction, and the catacombs themselves were abandoned and forgotten.

In order to understand how it was possible, in the centuries of persecution when the Christians themselves were often hunted down and martyred, for these proscribed groups to undertake and carry through the vast and costly task of creating the catacombs, it is necessary first to realize that the adherents of Judaism and other oriental religions established in Italy had long been privileged to prepare their own subterranean tombs and places of burial, and that the Christians were originally considered merely a heretical sect of Judaism. In the second place it should be noted that the earlier groups of Roman converts, far from coming exclusively from the lower ranks of the population as at one time supposed, in fact often included individuals of wealth and social position. Thus certain histories of early Roman martyrs tell how members of the aristocracy, wealthy patricians and noble ladies, piously gathered up the bodies of Christians who died for the faith and laid them to rest in their own private domains, proving that, besides slaves and artisans, there existed among the Roman Christians many rich and favored individuals, a few of whom belonged even to the imperial family. In the beginning, then, it was these wealthy Christians who undertook the expense of preparing the first catacombs, which were established on private properties belonging to the most illustrious converts to the religion of Christ. Their activities in this respect were also entirely legal, since the rights of the proprietor were absolute. He could receive and entomb on his own property outside the city whomever he pleased; and, once the body was deposited in its tomb, the universal Roman law intervened to assure its protection, declaring the grave a *locus sacer*, a place sacred and never to be disturbed. These legal dispositions and the ancient customs which backed them gave to the early Christians the means of assuring burial, without too great expense, to all members of their small communities. The Roman

catacombs were therefore founded and began their growth under entirely proper and legal auspices, and, whatever measures of proscription were launched against the Christians, they in general concerned only the living and rarely interfered with the abodes of the dead. This explains the names which came to be attached to the earliest cemeteries, such as the Catacombs of Domitilla, Praetextatus, and Lucina, so designated because they were excavated beneath the private burial plots of these well-to-do converts.

With the beginning of the 3rd century when the number of Christians at Rome had greatly increased and persecutions had intensified, the situation changed, and the status of the catacombs altered accordingly. It now became essential that the church should have its own burial places for the faithful, be they rich or poor; and so, from a donation made by an aristocratic family in the reign of Septimius Severus (c.193-211), the Christian community at Rome acquired a sepulchral area adjoining the crypt of Lucina on the Appian Way, which later became known as the Catacomb of Callistus from the name of the deacon to whom Pope Zephyrinus entrusted its management. Strange as it may seem, the existence of such church property, in the early 3rd century and during a period of the most violent persecutions, is attested by official documents which prove that, even in those difficult times, the Roman state permitted the Christian church to maintain its proprietary rights to the catacombs, although Christianity itself was then illegal and proscribed. The explanation of this seeming anomaly is generally held to reside in the great popularity and assured legal status of the contemporary *collegia funeraticia*, the "burial societies," also called *collegia tenuiorum*, "societies of poor folk," whose members were allowed by law to assemble monthly on a fixed date to make necessary arrangements in advance for the honorable burial of their members. Thus every *collegium*, whether Christian or pagan, set up its own treasury, elected officers to conduct its affairs, collected modest yearly dues from its members, and finally acquired outside the city a sepulchral area, which it excavated and caused to be prepared in common to provide a final resting place for every member. In this way, despite all persecution and proscription of the new religion, the Christian catacombs steadily expanded and increased in number until, with the final triumph of the faith in 313, they shortly ceased to be used as places of burial and assumed instead the role of venerated sanctuaries.

Early Christian writers, such as St. Jerome, Prudentius, and many others, bear witness to the devotion and respect inspired in the faithful from the 4th century onward by the tombs of the martyrs. Each year, on the day of their martyrdom, a solemn service of commemoration was held at the grave of the most illustrious victims of former persecutions now happily ended, when a subterranean mass was sung by candlelight, and processions of priests and celebrants moved along the gloomy galleries. Although such observances tended naturally to increase, it was largely through the enthusiasm of St. Damasus that the catacombs were developed as famous cult centers. The keen interest which this pope took in the old cemeteries during his pontificate (366-384) led him to carry out extensive works to make them more accessible and to render them more attractive to visitors. He thus caused certain galleries to be enlarged, stairways to be cut, and the tombs of eminent

martyrs to be redecorated and further signalized by metrical inscriptions, composed by himself with only mediocre poetical skill. The most famous of the underground chapels thus refurbished in the 4th century is the Grotto of the Popes in the Catacomb of Callistus, which received an altar and episcopal throne to honor nine popes, from Pontianus to Eutychianus, interred there. Although at this time many of the faithful still wished to be buried in the catacombs *ad sanctos*, that is, "near to the martyrs," all such burials ceased in the next century as a result of the evil days which then fell upon the Eternal City. With the sack of Rome by the Goths under Alaric in 410 and the subsequent pillage by the Vandals in 455, the inhabitants of the city no longer dared to venture beyond its walls to inter their dead in the catacombs. Instead they laid out more conventional graveyards in the devastated regions adjoining their urban churches.

Fig. 1. Plan of part of Catacomb of Domitilla, with Basilica built above Tomb of Petronilla.

Description.—We have seen that the Roman catacombs, with their vast complex of passages cut in the soft tufa rock, are located for the most part outside the city walls and along the ancient roads which radiate through the campagna. Excavated well beneath the surface, the narrow corridors, whose average width is less than a yard, extend often to great length (Fig. 1). Twisting and crossing at irregular angles, they give the impression not only of boundless extent but of hopeless intricacy as well, an impression much increased by the fact that they are seldom confined to a single level. Indeed, the Catacomb of Callistus has as many as six different levels of excavation, each with its maze of intersecting corridors from which open out the *cubicula*, or burial chambers, of various size and shape (Fig. 2). Since the entire wall space of corridors and chambers alike was utilized to the utmost for burials, the *loculus*, that is, the individual tomb, is itself in most instances merely an oblong niche cut into the wall, just wide and deep enough to receive the body. Here and there, however, larger rooms appear, which served as crypts to enshrine the bones of the martyrs. On the anniversaries of these saints, and often, too, when persecution raged, religious services were celebrated in these hidden oratories, so that the latter served occasionally as churches.

Those early Christians who had the task of planning, excavating, and decorating the prodigious maze of the Roman catacombs bore the modest title of *fossores*, that is, diggers or "sappers." The foremen of the individual gangs of workmen must obviously, however, have been trained in the

Fig. 2 Section of Catacomb of Callistus, showing six levels

exacting guild of Roman surveyors, the *agrimensores*, to have enabled them to cope with the unusual difficulties encountered in their subterranean labors. The nature of the obstacles they had to overcome can best be appreciated by recalling that they worked underground by the light of tiny flickering lamps, in a gloom which made it extremely difficult for their cuttings to follow a predetermined direction and thus avoid the waste of precious burial space. The disposal of excavated material was no less troublesome, since the greater part of it had to be carried laboriously to the surface on the backs of men, through passages so narrow that two workmen would be awkwardly cramped in passing. Yet generations of planners and laborers triumphed over all obstacles, carrying to completion through the centuries an unparalleled work of scientific skill and meticulous, exacting handicraft. Many frescoes show the fossors at work, mattock in one hand and a lighted lamp in the other. More frequently, however, they are portrayed on their tombs, as, for example, the 3d-century fossor Diogenes, who stands quietly in the painted niche above his grave, proudly bearing on his shoulder the mattock as symbol of his craft, his other tools disposed about him. In the early centuries such men even ranked among the minor clergy, as is indicated in this case by the swastika form of cross embroidered on his liturgical vestments (Fig. 3).

It is a significant fact that the entrances to the oldest Christian catacombs were of monumental aspect and opened directly on the main roads leading outward from the city. Thus the arcaded façade of the Catacomb of Domitilla, dating from the 1st century, is exactly like those of pagan tombs of the same period, its doorway leading to a vestibule from which stairways descend

to the labyrinth of corridors below. When the great persecutions of the 3d century were initiated, however, it became necessary to conceal the entrances, by placing them in open country far from the main routes, with nothing showing at the surface save a narrow stairway which could be quickly blocked and obscured. But, as the need for all such secrecy was removed by Constantine's edict of 313, the openings to the galleries were not only enlarged and beautified but often further signaled by the erection of a basilican church, dedicated to the memory of a famous martyr entombed below. A typical example of this is the basilica built above the tomb of Petronilla in the Catacomb of Domitilla (Fig. 1). We have already mentioned the subsequent efforts of Pope Damasus to make the catacombs more accessible to pilgrims.

At the entrance to the majority of catacombs a narrow stairway cut in the tufa leads downward from level to level, each marked by its maze of

Fig. 3. Arcossolium in Catacomb of Callistus with fresco representing the fossor Diogenes, 3d century.

galleries or *ambulacra*, the latter enlarged at intervals to become cubicles, which were generally excavated for well-to-do families or for the members of a *collegium*. The graves of the poorer Christians, however, were cut in the walls of the corridors, end-to-end and one above another so as to occupy the smallest possible amount of space (Fig. 2). In addition to these cramped loculi, three other types of tombs occur, namely, the *sepulcrum a mensa*, the *arcosolium*, and the sarcophagus. The last-named, a coffin of stone or marble often richly carved and hence extremely expensive, is not frequently found in the catacombs. The *sepulcrum a mensa*, or table tomb, is a somewhat more elaborate form of loculus divided into two equal parts in height, of which the upper is an entirely open rectangular niche. The lower half, which serves to receive the body, is hollowed out like a coffin and covered by a flat slab, thus suggesting a table (the coffin) set snugly in a niche of twice its height. The *arcosolium*, the most elaborate form of catacomb grave, resembles the foregoing save that the open space in the wall above the slab-covered coffin is cut in the shape of an arch, which makes a sort of canopy above the altar-like tomb (Fig. 3). This type, which came into use early in the 3d century, lent itself readily to decoration, realized generally in fresco but often carried out in applied revetment of colored marbles. From the artistic viewpoint it thus became the most important type of grave to be used in the catacombs.

Art.—To understand the art of the catacombs we must always bear in mind the fact that the earlier converts to Christianity were neither more nor less than Romans, or, at least, Latinized Greek and Oriental citizens of the vast Roman Empire. They were hence endowed with the classic background of the all-inclusive Roman culture. And, since the first adherents to the new faith were largely recruited in the more populous centers amidst the ferment of new ideas and doctrines preached by rival sects, early Christianity itself assumed a strongly urban and strangely cosmopolitan character. This significant, but generally disregarded, fact is pointed up in a graphic way by the epithet which the thriving Christian congregations came in time to apply to their rivals, more particularly to the less progressive groups of citizens who clung to the old traditional worship of the classic Olympian gods. As is generally the case, these more conservative and backward communities were those located in outlying rural districts, somewhat out of touch with more recent religious developments and naturally less exposed to the contagion of new ideas. These country dwellers, therefore, staunch adherents of the old religious beliefs, were mockingly labeled pagans, *pagani*, that is, yokels or country bumpkins, by the more sophisticated Christians of the crowded cities and towns.

That the fundamental basis of the life and thought of the early Christians was essentially Roman is amply demonstrated in all the forms of their art, most clearly in the catacombs and in their newly founded house of worship, the basilican church. The latter, indeed, clearly reveals the elements of which early Christian civilization itself was compounded, that is, its Roman classic core, on which was overlaid a thin veneer of mystic Eastern dogma. This latter component, however, the Oriental factor, was destined to receive an increasing emphasis during the first few centuries of our era. Originating in the East, the

new religion naturally embodied in its doctrines and basic concepts the mystic and lofty spirituality of the Orient. This, moreover, had been grandly focused in the person of a Founder who in all his recorded words and deeds had stood in direct opposition to the rational, objective, and non-spiritual ideals of classical civilization. Thus, from its very inception Christianity was by nature dualistic, drawing a sharp distinction between world and spirit, between the sinful flesh of man and the supreme goodness of God. Nevertheless, the ethical teachings of Christ, though accepted in theory, tended perhaps to be minimized by converts as yet unprepared to realize their full implications. On the other hand, the miraculous elements, the mystical ideas of spiritual regeneration through faith, of the salvation of the soul, soon crystallized in the form of dogma. It therefore happened that the converted pagans, who were called upon to express in the visible forms of art the ideals and doctrines of their new religion, found themselves faced by a difficult problem. The early catacomb artists, trained in the highly concrete and objective forms of Roman classic art, had now to present in terms of color and form a whole new series of concepts. Yet these new ideas, mystic and transcendental by nature, were by that very fact incapable of direct representation. How, for example, shall we paint the form of the Holy Spirit? How can we show in visible form the salvation of the soul, the resurrection of the body and life everlasting? This was the problem, more difficult by far than that which confronted the pagan artist. It admitted, of course, of but one solution—the use of symbols. From its beginnings in the catacombs, therefore, Christian art was necessarily symbolic.

Symbolism.—Although symbolism attained its peak in Christian art, its use for the representation of religious ideas had been common among all ancient peoples, so that, with such a long tradition behind it, the symbolic habit of thought came naturally to the Roman artists of the catacombs. Their task was rendered more difficult, however, by the fact that they had now to deal with abstract and mystical concepts. The first efforts of this great symbolic art and its early struggles with a mode of utterance still largely pagan are most graphically illustrated in the frescoes of the Roman catacombs. In completing a burial of the types described above, the tomb was tightly sealed with slabs of stone or tile, and upon this covering an inscription was cut or painted. In many instances, particularly in the larger crypts and cubicles, the rough tufa walls were smoothed and coated with stucco, and on this the celebrated scenes and decorations were painted in fresco. Among them, however, the modern observer is struck by the very significant and almost complete omission of any reference to the passion of Christ and, more particularly, to His crucifixion. This seems the more strange because in later centuries these subjects became of supreme artistic and religious importance. The truth of the matter is, of course, that the early Christians were much too close in point of time to the actual sufferings of their Lord to forget the ignominious nature of the punishment He had suffered, a punishment reserved in Roman law for the lowest and most desperate type of criminal. Small wonder, therefore, that even in the latest catacomb paintings the crucifixion was not represented or, in fact, the symbol of the cross itself. We could as well expect an obscure modern sect,

whose founder, let us suppose, had died at the hands of the law, to adopt for the supreme symbol of its faith the noose or the electric chair. Instead of the cross, then, we find in catacomb frescoes of the early 4th century the symbol known as the *chrismon*, the Constantinian monogram of Christ, which seems to represent schematically the flaming cross, said to have been seen in the heavens by Constantine at the Battle of the Milvian Bridge (Fig. 4). In this symbol, *chi* and *rho*, the first two letters of Christ's name in Greek, are superposed to produce a six-armed wheel-like form, which only remotely suggests the chief instrument of the passion. Later, however, when crucifixion as a punishment for criminals had long since been abolished and the stigma attached to this form of torture generally forgotten, the cross gained gradual acceptance as the chief symbol of the Christian religion.

Fig. 4. Chrismon, or Constantinian monogram of Christ.

Frescoes.—The catacomb paintings, done in rather brilliant colors in a sketchy rapid style, show close analogies to the well-known Roman frescoes at Pompeii. The earlier examples, at least, from the 2d century of our era, might well be mistaken for Pompeian work, particularly in their open composition and in their use of naturalistic ornament. Indeed, it is only in their symbolic aspect that their specifically Christian character resides. The actual scenes represented deal for the most part with incidents from the life of Christ, particularly the miracles, or with a restricted range of Old Testament stories. Among

employed in sepulchral art. Hence the majority of these scenes, repeated over and over with slight variation in the frescoes, symbolized in one way or another the idea of the salvation of the soul.

One of the earliest of these paintings shows Daniel in the lions' den. The prophet appears as a youthful nude figure of Roman classic type, his hands raised and extended in the pagan attitude of prayer, while on his right and left are posed in heraldic fashion two quite innocuous lions no larger than fair-sized dogs. The den or any other indication of surroundings is entirely omitted, since the scene, in deference to its purely symbolic purpose, is reduced to its lowest terms and presented in the simplest possible manner. In even balder simplicity is pictured the symbolic incident from the story of Noah. Upon a groundline which represents the waters of the flood the ark appears, quite literally as a cubical box or *arca*. From it emerges the upper part of a single draped figure, Noah, who stretches forth his hands to receive the sprig of olive from a dove fluttering overhead. The illustration of the story of Jonah naturally demanded a more extended composition, since three successive incidents had to be shown (Fig. 5). In the first a small Roman ship bears several oversize sailors, who hurl the unfortunate Jonah headlong into the sea. Yet the lurking whale that awaits with gaping jaws the disobedient prophet is no whale at all to modern eyes, but rather a typical hippogriff, the common classic sea monster. From snaky coils and splashing forelegs it rears a doglike head, the jaws of which are studded with bristling fangs. Immediately adjoining, we again see the monster in much the same attitude as before, but here its head is toward the shore and from its widely opened mouth the form of Jonah plunges, with arms extended to break his fall. In the third scene Jonah reposes under the gourd vine which Jehovah caused to grow and wither again next day as a sign unto him.

Fig. 5. The story of Jonah, fresco in the Catacomb of Callistus, late 2d century.

the latter, the most frequent are Moses striking the rock from which water gushes, the three children of Israel in the fiery furnace, Noah in the ark welcoming the dove with the sprig of olive, Jonah thrown to the whale and cast up safe on shore, and Daniel in the lions' den. These scenes were obviously chosen as peculiarly fitting for sepulchral use, and it seems equally clear that they did not come directly from the Bible, but rather from early prayers and liturgies for the dead, like a prayer which is still used in the Roman Church, and from which the following verses may serve to illustrate the type: "Deliver, O Lord, the soul of thy servant as thou didst deliver Noah from the deluge. Deliver, O Lord, his soul as thou didst deliver Isaac from sacrifice. Deliver, O Lord, his soul as thou didst free Daniel from the den of lions." And so the prayer continues with the same formula, listing almost all the Old Testament subjects which are

These three closely connected incidents rank among the most popular subjects figured in the catacombs. Not only did they symbolize in general the salvation of the Christian soul, but, more specifically, the death and resurrection of Christ himself; hence, more broadly, they expressed the belief of the individual Christian in the resurrection of the body and life everlasting. For, just as Jonah abode for two days in the belly of the whale and on the third was cast up safe on shore, so did Christ descend to the tomb and on the third day rise again from the dead. But, in addition to this symbolic message expressed in forms entirely Roman and classic, another important feature demands attention, the use by the artist of the continuous method, the so-called narrative style, in which, by the repetition of the figure of Jonah in successive phases of action, his story is simply and graphically told. This vivid narrative style, used so effectively to expound Christian doctrine

throughout the Middle Ages and recently revived in the modern comic strip, provided the Christian artist with an essential means for realizing the chief purpose of his art, that of teaching Christian dogma to a largely illiterate people.

To us of today, as doubtless to the early believers themselves, the scenes of the life and miracles of Christ were endowed with peculiar significance. Appearing first in the catacombs and thereafter of wide appeal is the story of the adoration of the Magi. Approaching from right and left the seated Virgin, who holds the Child, come the wise men of the East with their gifts. And, that no one may mistake their Eastern character, they are clad in Persian garb, with conical hats, flowing capes, and full trousers. The baptism of Christ, on the other hand, is figured with the utmost classic simplicity. John stands nude at the water's edge, extending his hand to Christ, who approaches from the bank, and both are Roman classic figures, youthful and unbearded. Were it not for the dove of the Holy Spirit which appears above, they might well be taken for a

paradise wherein the risen soul praises God for evermore. On good scriptural authority Christ himself was early figured as a lamb, the Lamb of God; and strangely, also, as a fish, often shown together with a basket of rolls, referring both to the Eucharist and to the miracle of the loaves and fishes (Fig. 7). The fish symbol was arrived at in a curiously fortuitous manner. Thus, if one writes in column the Greek words meaning "Jesus Christ of God the Son, our Saviour," and reads in order the initial letter of each, the letters in

question form the Greek word *ichthys*, meaning "fish." More important, perhaps, was the representation of Christ the Good Shepherd, a symbolic type which plays an important role not only in the catacombs but also on sculptured sarcophagi and in the mosaics of early churches (Fig. 8). The Good Shepherd, as shown in these works, appears as a simple Roman with youthful classic features, a fair unbearded face often framed in curling locks of hair, and the graceful bodily pose of a young athlete. He is clad in a short tunic

Fig. 6. *Orans in Paradiso*, with inscription reading "Dionysias in Pace," fresco in the Catacomb of St. Soter, end of 3d century.

couple of young Romans about to plunge into a country stream. From the miracles of Christ the scenes most often represented are the multiplication of the loaves and fishes, the transformation of water into wine at the marriage in Cana, the healing of the paralytic and the raising of Lazarus. In each case the style is entirely Roman, while the action, reduced to its lowest terms, is shown with the minimum number of figures. Thus, for example, in the healing of the paralytic is sketched the single figure of a man who bears a couch on his shoulders: "Arise, take up thy bed and walk." Although Christ himself does not appear, the essence of the miracle is unmistakably represented.

A third group of subjects, those of a more abstract symbolic nature, present the idea of heaven, the ultimate beatitude of the soul. Chief among them is the figure of the *Orans in Paradiso* (Fig. 6). Man, woman, or child, as the case may be, the *Orans*, clad in festal garb and with hands uplifted in prayer, stands upright in the midst of a beautiful garden sketchily represented by a few flowering shrubs. This is the

Fig. 8. The Good Shepherd, fresco decoration in ceiling of the Catacomb of Lucina, first half of 3d century.

girded above the knees, and his feet and legs, though sometimes bare, are generally shod and protected by stout leggings. One hand grasps on his chest the legs of a sheep across his shoulders and the other holds his staff, jug, or musical pipes, while to his right and left repose other sheep in a schematic landscape setting. Nothing could have comported better with the spirit of early catacomb art than this symbol, which reveals its strongly classic basis, its essentially Roman vocabulary, and its abstract Oriental content.

Sculpture.—Doubtless because of their profound aversion to graven images, the Christians of the earlier centuries produced almost no sculpture, so that only with the era of peace did wealthy converts begin to use sculptured sarcophagi. And here again, just as in the frescoes, the only feature which distinguished these from pagan works of the same period resides in the symbolic meaning and specifically Christian content of the scenes and persons represented. The so-called Jonah sarcophagus, now in the Lateran Museum, follows almost exactly in iconography and symbolic purpose the subject matter already noted in the frescoes; but also, in order to enforce the doctrine of the resurrection of the body and life everlasting, the artist added the familiar scenes of the raising of Lazarus, of Daniel in the lions' den and of several others whose meanings are more difficult to determine. Several marble statues of the Good Shepherd have been discovered, and a seated figure of St. Hippolytus, found in the catacomb of his name, shows inscribed on his cathedra a list of his works and his computation of the Easter cycle for the years 222-334.

Gold Glasses.—The gold glasses, of which many have been discovered in the catacombs in a more or less fragmentary condition, were blown in the usual way of clear greenish glass and were decorated with figures, portraits, symbols, and even miniature scenes in the form of gold-leaf silhouettes. When the vessel itself had been shaped, fashioned, and allowed to cool, the delicate figures were worked on its bottom or sides in applied gold leaf, and the entire decoration was then protected by a thin outer layer of glass. Although scholars disagree as to when and where the technique of gold-glass originated, the art seems to have fallen almost exclusively into the hands of Christians after the middle of the 3d century. It is, at any rate, only Christian examples that have been found in large numbers, their importance depending less on artistic quality than religious content, although for the most part they merely repeat familiar subjects drawn from the repertoire of the frescoes or the sarcophagi. In certain significant aspects, however, the Christian specimens continued pagan tradition by showing portraits of a married pair or family group, giving their names and often, also, the revealing inscription, *PIE ZESES*, "Drink!—and long life to you!" a Greek toast written in Latin letters. It is hence clear that the cups were made locally and on order for convivial occasions, marriage feasts, and funeral banquets, traditional observances which the Christians inherited from their pagan Roman forebears. And, since they bore not only portraits but also the names of the persons represented, the bottoms of such cups were often pressed into the fresh plaster on the walls of the catacombs to identify the place of their owner's entombment. This custom accounts for the large number of these fragile objects preserved to the present day. Yet the vogue which they enjoyed did not long outlast the end of the 4th century, at which time it seems that the church was obliged to suppress the feasts they served, since the latter obviously did not comport with true Christian sobriety.

Minor Arts.—From the galleries of the catacombs and even from the tombs themselves have come a considerable number of minor objects such as rings, seals, coins and medals, as well as combs and buttons of carved ivory, and even children's toys. Clay lamps are most frequently found, the

majority differing in no respect from those used by the pagans. In the 3d and 4th centuries, however, they were marked with Christian emblems such as the fish, the chrismon, and the Good Shepherd, affording graphic illustration of the extent to which the Christian faith had come to penetrate and sustain domestic life.

Inscriptions.—To give an adequate account of catacomb epigraphy in a brief paragraph is obviously impossible, yet the numerous inscriptions found in the catacombs are of prime scholarly interest because of the light which they throw upon dogma, or upon the conditions of civil and religious life. As to method of execution, they were either carved on slabs or tomb markers, painted on the frescoed walls, or rudely scratched as graffiti on the plaster or tufa. An important distinction to be drawn is that between the original titles and epitaphs, and the later inscriptions in verse with which Pope Damasus and his followers adorned the tombs of saints and martyrs. Most of the very early inscriptions in the catacombs were in Greek, although sometimes written in Latin characters as we have already observed in the gold-glass cups. The early epitaphs are usually very brief, giving the name of the departed, with a short prayer and a symbol such as the fish, anchor, or chrismon, to which are occasionally added the date of burial and age. The most common type of inscription, however, is that accompanying the *Orans* in Fig. 6, "*Dionysas in pace*," "*Dionysas rest in peace*." Especially strong is the testimony of the catacombs to prayers for and to the dead, as appears from a well-known epitaph of the Catacomb of Domitilla, which reads as follows: "Gentianus the faithful, in peace. He lived twenty-one years, eight months and sixteen days. In thy petitions pray for us, because we know thou art with Christ."

CATACOUSTICS, kăt-â-kōōs'tîks, the science which treats of reflected sounds, or that part of acoustics which considers the properties of echoes.

CATAFALQUE, kăt'â-fălq (French from Ital. *catàfalco*, scaffold), a temporary richly decorated structure, usually erected in a church, upon which is placed the coffin or the effigy of an eminent person at his funeral ceremonies. The catafalque was introduced into France in the early centuries of the monarchy. Among famous catafalques was that designed by Italian artists in the nave of San Lorenzo, Florence, to honor Michelangelo; the one erected in the Hôtel des Invalides, Paris, in 1840, for the remains of Napoleon I brought from St. Helena; and that erected under the Arch of Triumph in Paris in 1885, on which the body of Victor Hugo lay in state for several days before the imposing public funeral in the Pantheon.

CATAGENESIS, kăt-â-jên't-sîs (Gr. κατα down, and γένεσις generation), in biology the retrogressive evolution of living species. The

term is used to describe two different orders of phenomena. Primarily it is applied to regression as observed, for example, among parasites which, gradually adapting themselves to parasitic existence, lose part of their organs and are transformed into a digestive and generative sac. Similarly it applies to species forced to continue living in an environment which has become unfavorable to them, as in the case of some insular species. Secondly, the term catagenesis can signify, by opposition to anagenesis (reproduction or regeneration of tissue), the disappearance of certain characteristics no longer useful. Thus the more or less frequent absence of wisdom teeth among civilized people is a catagenetic phenomenon.

CATALAN, a native of Catalonia (q.v.) and certain other parts of northeastern Spain. For the language, see CATALAN LANGUAGE and CATALAN LITERATURE.

CATALAN FORGE is a hearth type furnace for smelting iron ore which originated in Catalonia, Spain, about 1300 A.D. and spread throughout the world. It probably evolved from a stone-lined hole in the ground to a brick-lined hearth.

The hearth, 30 inches square and 3 feet deep, was half filled with a charcoal and iron ore mixture, more charcoal was placed at the back and ore at the front of the hearth. An air blast entering the back of the hearth burned the charcoal, the carbon monoxide thus generated reducing most of the iron oxide in the ore to iron and the charcoal the remainder. Water falling in a tube sucked in air which was trapped in a box below and delivered through the tuyère to the hearth; water escaped near the bottom of the box. That combination of water, tube, and box is called a trompe. The loop (Fr. *loupe*), spongy reduced iron, was not hot enough to melt. While hot, it was lifted from the hearth and hammered into a cake or bar.

It is believed that the Catalan forge was the first large scale smelter, producing up to 350 pounds of iron during a five-hour period.

CATALAN GRAND COMPANY, a name of a troop of mercenary soldiers, called Almúgavars, raised by Roger de Flor (q.v.) about the beginning of the 14th century. After giving his services to Frederick II, king of Sicily, Roger proposed to maintain the soldiers by taking them to the East to fight the Turks, who were desolating the Eastern Empire.

Andronicus II, then emperor, gladly accepted the offered assistance of Roger and submitted to all the conditions imposed. Roger set sail from Messina, Sicily, in 1303, with 26 vessels partly equipped at his own expense. The number of mercenaries which embarked with him is said to have amounted to about 6,000 men of different nations among which were Sicilians, Catalans, and Aragonese. The Catalans, either because they were the most numerous or for some other reason, gave their name to the whole company.

On his arrival at Constantinople, Roger was received with great rejoicings and was elevated to the dignity of grand duke. A bloody affray between the Genoese and the Catalans marked the first period of adventures in Constantinople. Andronicus hastened to get them to cross over into Asia. This they did in the spring of 1304 and in the same year completely defeated the Turks.

They then forced the Turks to raise the siege of Philadelphia, but an attempt to take Magnesia was not so successful. After a long and ineffective siege he recrossed into Europe in 1306, bringing along with him his Catalans, who left behind them everywhere traces of their plunder and violence. When they reached Europe they took up quarters at Gallipoli.

Andronicus, who was by this time very anxious to be rid of his formidable allies, received Roger with great coldness and even obliged him to give up his title of grand duke. But simultaneous incursions of the Turks into Asia compelled Andronicus again to appeal to Roger and his Catalans for assistance. Roger was raised to the dignity of Caesar to appease him for the recent affronts, but this only caused him to be regarded with more jealousy by the Greeks and especially by Michael IX, the son of Andronicus, who was associated with his father in the empire. The result was that before Roger could once more start for Asia, he was invited to Adrianople by Michael, who contrived his assassination and the massacre of his troops, April 4, 1306. The Catalans now turned their arms against the Byzantines, in order to avenge the death of their leader, and defeated them in several battles. Then they passed into Greece and entered the service of the duke of Athens, but shortly afterward turned against him and defeated him in 1311. They then became masters of Attica and established their own dynasty which lasted until its overthrow by the Florentines in 1388. See also GREECE—*History of Byzantine Period: 330–1453* (The Situation in Greece).

CATALAN LANGUAGE. Fundamental Concepts.—Catalan is one of the nine Romance languages, those derived from Latin. Its geographic location in the northeast corner of ancient Hispania has made Catalan a language bridge between the Gallo-Romance and the Ibero-Romance dialects. Catalan was for many years considered a dialect variant of Provençal, and only around 1925 was there unanimity in placing Catalan in the category of an independent neo-Latin language. It should not be imagined that Catalan is a dialect of Castilian or Spanish merely because the latter is the official language of all Spain. There are two opinions as to which of its Romance neighbors Catalan resembles more: one holds that Catalan should be classed with the Gallo-Romances (W. Meyer-Lübke, *Das Katalanische*, 1925); the other, that it be classed with the Ibero-Romances (R. Menéndez Pidal, *Orígenes del español*, 1926). Catalan is a language fundamentally Hispanic in origin, but with the developing Reconquest the territory of this incipient Romance was more oriented towards the north, and consequently it developed many linguistic traits similar to those of Provençal.

The basis of Catalan is, of course, the Latin spoken by the masses and the Roman middle classes. In the different zones that can be outlined in Vulgar Latin, Catalan sometimes coincides with the Hispanic Romances (*cova*, Sp. *cueva*, "cave," Lat. *cova*); other times it coincides with the central portion of Rumania (*parlar*, Sp. *hablar*, "to speak," Lat. *parabolare*); and still others it has forms found in neither neighboring group (*desar*, Sp. *guardar*, "to keep," Lat. *densare*). The Catalan lexicon, in addition to the Vulgar Latin fund, was enriched by many contributors: classical Latin (learned words), Greek (ancient

and medieval words, modern technical terms), pre-Romance languages (words from Iberian, Celtic, Ligurian, Phoenician), Germanic (Latinized Germanic words, proper names), and Arabic (many terms and a great number of toponyms). Following its constitution as a language Catalan has received elements from Provençal, Spanish (and through it, from the American Indian languages), French, Italian, and to a lesser degree English and German.

Catalan is spoken in an area comprising: Catalonia, except the Valley of Arán (where Gascon is spoken); Valencia, excepting some regions in the west; the Balearic Islands; almost all the French department of Pyrénées Orientales; Andorra; the city of Alghero (Sardinia); a strip along the east of the provinces of Huesca, Zaragoza, and Teruel. To the north Catalan is bounded by Provençal and Gascon dialects, and to the west by the surviving forms of Old Aragonese and by Castilian. The total population in the domain of Catalan exceeds 5 million inhabitants: 4,775,000 in Spain; 238,000 outside Spain. In spite of the centuries of decadence, and in spite of the fact that it is not the official language, Catalan has maintained its vitality. This is a very important factor since the modern revival and the great work in purifying and fixing of the literary language would serve nothing if the people, individual speakers of the language, felt it to be foreign to them. Medieval Catalan of the chanceries was used in literature to the exclusion of latent dialectal forms and the latter did not manifest themselves until the 16th century. In the mid-20th century the dialects can be defined as (1) the eastern dialects: central (Barcelona, Girona, Tarragona), Balearic (in the Balearic Islands), Roussillon (in Roussillon, France), Algherian (Sardinia); and (2) the western dialects: Leridan (Lérida), Valencian (Valencia).

Linguistic Features.—**Pronunciation.** Catalan distinguishes the open vowels *e*, *o* as phonemes distinct from the corresponding closed vowels. (Castilian has only open and closed variants of the single phonemes, *e*, *o*.) In the speech of Barcelona unaccented *a* and *e* are pronounced as an indistinct neutral vowel, and unaccented *o* and *u* are pronounced as *u*; but the western dialects distinguish clearly between *a* and *e* and between *o* and *u*. Catalan has the apico-alveolar articulation of the *s*, as in Castilian (and as opposed to the European predorsal *s*). It has a series of palatals based on *x* and *j*; an articulation of *l* with strong velar resonance; and the Old Romance affricates *ts*, *dz*, *tx*, *tj*. In syntactic phonetics, voiceless consonants (except occlusives and liquids) become voiced in word final position and before a following vowel (*els astres* "the stars" is pronounced *elastres*).

Phonetics.—Catalan is distinguished by the absence of spontaneous diphthongization of short Latin vowels: where Castilian has *bien*, *buena*, Catalan has *bé*, *bo* (Lat. *bēne*, *bōnu*); in principle it preserves the original vowels *a*, *i*, *o*, *u*; Vulgar Latin *e*'s produce mixed results, differing according to dialects; the vowels tend to combine with a palatal (the yod) or a velar (the wau) with which they are in contact and close their articulation, thereby reducing the diphthong: Lat. *laicu* gives Cat. *llec* "lay," Lat. *auru* gives or "gold," so that it may be said that there is a vocalic closing due to the effect of the yod or wau. The Catalan consonant system is characterized by the palatalization and assibilation of

consonants in contact with the vowels *e* and *i* (*ciutat* "city," Lat. *civitate*), or in contact with a yod (*acer* "steel," Lat. *aciariu*); by the relaxation of consonants whereby the voiceless become voiced (*nebot* "nephew," Lat. *nepote*), the voiced consonants at times disappear (*suor* "sweat," Lat. *sudore*). This relaxation explains the vocalization of the final (or equivalent to final) consonant into *-u* (*hereu* "heir," Lat. *herede*). In groups of two consonants the first is weakened and at times tends to be assimilated by the second (*neta* "granddaughter," Lat. *nepta*), and at times tends to be converted to a semivowel *u* or *i*; the semivowel thus formed then either combines with the preceding vowel or is absorbed by it (*om* "elm," Lat. *ulmu*, which presupposes in intermediate form **oum*; *fet* "deed," Lat. *factu*, which presupposes **fait*), or it may palatalize the second consonant of the group (*cunyat* "brother-in-law," Lat. *cognatu*, which presupposes **coinat*).

Morphology.—The derivation of the words from Latin is based on the Latin accusative forms, although there are unquestionably some words derived from other Latin cases, especially from the nominative (*res* "thing"). Latin adjectives with only one form tend to take on a specific ending for the feminine, generalized in a few instances (*fort*, *forta* "strong," Lat. *forte*), but with greater extension in the popular speech (*fàcil* "easy" has the popular feminine form *fàcila*, not recognized as correct). The article normally comes from Lat. *ille* (*el*, *la*), but in preliterary Catalan there existed, with wide usage, the article derived from Lat. *ipse* (*es*, *sa*), still used in the Balearic Islands and on the Costa Brava in Catalonia, and can also be found fossilized in toponyms in much of Catalonia (*Collsacabra*, *St. Joan Despi*). The four Latin conjugations have been preserved in Catalan, although in different proportions: *cantare* > *cantar*, *habēre* > *haver*, *perdere* > *perdre*, *venire* > *venir*. Characteristic of the Catalan perfect tense is its almost universal replacement by a periphrasis with the present of the verb *anar* "to go" (*vaig* "I go," *vas* "you go"); *vaig cantar* means "I sang" (the same as *canti*), *vas cantar* "you sang" (as *cantares*).

Syntax.—Catalan constructs the determinatives of quantity with a partitive: *molt de temps* "much time" (compared to Sp. *mucho tiempo*). Catalan admits some adverbs for the expression of pronominal relations, such as *hi* "in it" (Lat. *ibi*) and *en* "of it" (Lat. *inde*). It distinguishes, as does Spanish, between the two intransitive copulative verbs *ser* and *estar*, but the languages do not coincide in the distinction; for example, temporary state is expressed in Catalan with *ser* and in Spanish with *estar*. In opposition to the use, waxing since the Middle Ages, of the subjunctive mood in Spanish, Catalan prefers other expressions, such as the future (*quan tornaràs* "when you return," Sp. *cuando vuelvas*), the imperfect (*si tu volies* "if you wanted," Sp. *si tu quisieras*), the conditional (*no t'ho hauria dit* "I should not have told you," Sp. *no te lo hubiera dicho*). The past participle in compound tenses, invariable in Spanish, agrees in Catalan with the direct object: *l'ha conegut* "he has known him," *l'ha coneguda* "he has known her," compared to Spanish *lo* or *la* *ha conocido*.

Modern Catalan Philology.—This work began with the endeavors of A. Alcover and his *Bolletí*

* The asterisk indicates a hypothetical intermediate form.

del *Diccionari de la Llengua Catalana* (since 1901), directed toward the collection of material to comprise the *Diccionari Català-Valencià-Balear*, which began to be published in Majorca in 1930. Impetus was further given to the study of Catalan by the *Primer Congrès Internacional de la Llengua Catalana* in 1906, and by the interest on the part of many publishers to print editions of medieval Catalan texts. The Institut d'Estudis Catalans, founded in 1907, fixed Catalan orthography in 1913, and such important works were undertaken as the *Butlletí de Dialectologia Catalana* (since 1913) and the *Atlas Lingüístic de Catalunya* (1923) by A. Griaer, and there was an active personal and scientific participation in international Romance studies. Almost 50 years after the Congress of 1906, Barcelona was the scene of the Seventh International Congress of Romance Linguistics (April 1953), which saw a recapitulation of more than half a century of Catalan philology, focused the attention of the more than 250 delegates on the problems of Catalan and marked a new stage in recent studies.

Professor of the University of Barcelona.

CATALAN LITERATURE. Literature in the Catalan language has two periods of development: the first extends from the beginning of the 13th century to the end of the 15th, and the second begins around 1833. Collaborators in this literature are not only writers born in Catalonia but also those from the old kingdoms of Majorca and Valencia and the province of Roussillon (the latter now a part of France), regions in which Catalan is the vernacular. A collection of sermons, *Homilies d'Organyà*, of the beginning of the 13th century, is considered the oldest literary text in Catalan, although its principal value is linguistic. In that period Provençal, another Romance language and a neighbor of Catalan, was studiously cultivated in Catalonia by learned or aristocratic Catalan poets, owing to the frequent historical and political relations the counts of Barcelona and the kings of Aragon had with the lands of southern France. The court of Barcelona received many Provençal troubadours and as a consequence the Catalan courtiers wrote their verses in Provençal, among them being King Alfonso II of Aragon (1152-1196), whose dominions extended north of the Pyrenees. Among the troubadours born in Catalonia should be mentioned the cynical and brutal Guilhem de Berguedan, the refined and delicate Pons de la Guardia, and Guilhem de Cabestanh (12th century), and the prolific and varied Guilhem de Cervera, called in troubadour fashion Cerverí (13th century). This poetry exercised a strong influence in the learned Catalan poets of the 14th century, who followed faithfully the themes, the style, and in part the language, of the classic Provençal troubadours.

Medieval Period.—Genuinely Catalan prose reached its greatest perfection in the extensive work of that important figure, the Majorcan Raymond Lully (Cat. Ramón Llull, Lat. Raimundus

Lullus, 1233-1315). Some 250 authentic works of Lully have been preserved in which are expounded his ideas of philosophy and his missionary zeal. From the point of view exclusively literary he is a true artist of Catalan prose, in which language he wrote books on science and philosophy at a time when these subjects were normally treated in Latin. His principal works are his lengthy *Libre de contemplació . . .* (*Book of Contemplation . . .*), an impressive climax to his mystic experiences, his Utopian novels *Libre de meravelles* (*Book of Marvels*) and *Blanquerna*, and his collection of short prayers called *Libre d'Amich e d'Amat* (*Book of the Lover and the Beloved*), an ejaculatory of Christian lyricism. In his verse Lully used a language closer to Provençal than to Catalan, as can be seen in *Lo Desconhort* (*Despair*), a poem written in a moment of acute pessimism, and in the *Plant de Nostra Dona . . .* (*Lament of Our Lady . . .*), a sort of *Stabat Mater*. A contemporary of Raymond Lully was the famous doctor and visionary from Valencia, Arnau de Vilanova (Arnaud de Villeneuve, c.1238-1311), who, although generally using Latin, wrote brief treatises in Catalan in the form of disputes or debates, of which four have been preserved.

Historiography constitutes the most important element of Catalan prose of the 14th century. Four great chronicles stand out: the oldest of these is the *Libre dels feyts* (*Book of Deeds*), in the redaction of which King James I of Aragon (1208-1276) took a leading role (the extant text is a later revision dated between 1313 and 1327). This chronicle narrates principally the conquests of Majorca and Valencia and is the prosification of epic poems now lost. Bernat Desclot wrote between 1285 and 1295 a *Crònica* devoted for the most part to the deeds of King Pedro III the Great; it is strongly dramatic in the description of early events in the expansion of Aragon through the south of Italy, and especially in describing the war of Catalonia against the invading French. The *Crònica* (written in 1325) of Ramon Muntaner (1265-1336) is unforgettable for its familiar and colorful style, as it narrates with detail and emotion the Catalan expedition to Greece and Asia Minor, the chronicler having been one of the leaders of the expedition. The last of the four chief chronicles is that written by King Pedro IV the Ceremonious (with several collaborators) and which has a more political character; it was finished in 1388, a period in which Catalan prose was being renewed thanks to Humanism.

An excellent narrator and the writer of pleasant and attractive prose is the Franciscan Francesch Eiximenis (1340-1409), author of *Lo Chrestia*, a monumental encyclopedia similar to the medieval *Summae*, and of a didactic work, the *Libre de les dones* (*Book of Women*), a very colorful work abounding in odd bits of information. The chanceries of the kings of Aragon (counts of Barcelona), thoroughly organized by the mentioned Pedro IV, formed a sound intellectual center in which the royal secretaries of the end of the 14th century occupied themselves with the Humanistic and Ciceronian editing of Latin documents. This style immediately was adapted to Catalan documents, thereby giving to the prose an elegant Renaissance form. One such notable royal secretary was Bernat Metge (1350-1413) of Barcelona, who was much influenced by the Latin works of Petrarch and Boccaccio. In his

Lo somni (*The Dream*), a treatise written in 1398, Bernat Metge incorporated the new ideas of the Italian Renaissance and at the same time gave a Humanistic cultured and measured elegance to Catalan prose. His followers were a large number of Humanists, strongly influenced by Italy, most of whom were translators of the Latin classics. Worthy of note towards the end of the 15th century is the prose of the Valencian Joan Rois de Corella (1430-1500), an elegant adaptor of Ovidian fables in an excessively rhetorical style.

In the lyric of the end of the 14th century the prominent poets are Andreu Febrer and Gilabert de Pròxita, still influenced by Provençal tastes. Jordi de Sant Jordi (beginning of 15th century) was a courtly poet of delicacy who united in his work the preciousness of Arnaut Daniel and the tenderness of Petrarch, imitating each at times. The best of the Catalan lyric poets was the Valencian Ausiàs March (1397-1459), falconer to King Alfonso V the Magnanimous (Alfonso I of Naples). Ausiàs March, writing in a Catalan free from Provençalisms, analyzed scholastically his fancies and his passions in a personal and vigorous style. He put poetry at the service of a profound introspection, tortured and obsessive, which secures for him a position of singular importance in the medieval Romance lyric. The principal qualities of his style are his many comparisons (frequently referring to the sea) and the proud, high-sounding tone that he acquires on occasion. The 15th century is brightened by a multitude of Catalan poets, at times influenced by the Italian or by the courtly French lyric; among these are Pere Torroella (also a cultivator of Castilian poetry under the name of Pedro Torrellas) and the refined Rois de Corella, already mentioned as a prose writer.

The Catalan novel began with versions of French prose texts concerning the Holy Grail and Tristan, novels of chivalry. In the mid-15th century two important novels of chivalry of Catalan origin appeared: the anonymous *Curial e Güelfa* revealing French and Italian influences, and *Tirant lo Blanch*. The latter was written by the Valencian knight Johanot Martorell and is one of the most interesting of medieval novels for its realism, its naturalness, and its exactitude in the creation of atmosphere, types, and situations. This novel was known and even imitated to a degree by Ariosto and Cervantes. Within the classification of the novel falls the satiric treatise by the renegade Majorcan Anselm Turmeda entitled *Disputa de l'Ase* (*Dispute of the Ass*) whose original text, written in 1417, has been lost, but which has been preserved through a French version printed in 1544. Although written in narrative verse *Spill* (*Mirror*), 1460, the work of the Valencian Jaume Roig (d. 1478), is really a novel in content: the protagonist, a hapless young man, relates his adventures with bandits and his marital misfortunes; in certain respects *Spill* is a forerunner of the Castilian picaresque novel.

Catalan oratory had many cultivators among the parliamentarians, and outstanding in this field were the discourses delivered by King Martín I. San Vicente Ferrer (1350-1419) was an impassioned and popular orator, making frequent references to daily life and customs and not disdaining to use the language of the people. (The Italian orator Bernardino of Siena openly imitated Ferrer.) A solemn and learned orator was Felip

de Malla, of whose works have been preserved some speeches and a rhetorical, allegorical treatise called *Memorial del peccador remut* (*Memorial of the Redeemed Sinner*).

Decadence and Revival.—From the beginning of the 16th century until the middle of the 19th Catalan letters languished, due chiefly to the disappearance of the court, the real nucleus of medieval Catalan literature, which was essentially courtly. Catalan and Valencian authors increasingly wrote in Castilian, attracted by the splendor of Golden Age Spanish. Notwithstanding, Catalan continued as the official language in Catalonia with no governmental interference until 1714, when Philip V of Spain, grandson of Louis XIV, imposed absolutism of the French type. In the following century Romanticism produced a revival of Catalan literature (called *Renaixença*, which began with *Oda a la Pàtria* (1833), a perfect ode composed in Madrid by the erudite Buenaventura, Carlos Aribau. There immediately followed a series of attempts directed toward reviving the ancient Catalan literature and restoring to the language a literary dignity. In this effort Catalan writers received the collaboration of Majorcans, to a lesser degree of Valencians, and sporadically of Roussillon writers. Poetry contests, called *Jocs Florals*, initiated in 1859 and still held throughout Catalonia, gave great popularity to the *Renaixença*. The most important figure of later 19th century Catalan literature was Jacinto Verdaguer (1845-1902), a poet of fecund and overflowing imagination as much in his epic, exemplified by his poems *L'Atlàntida* (in which he joined classic mythology to the discovery of America) and the *Canigó* (a medieval legend of the Pyrenees), as in his mystic Franciscan lyric. The poet Joan Maragall (1860-1911) displayed a sincere accent of intimacy in committing his delights, his sorrow, and his impressions to a suitable elevated lyric. The Majorcan poets, especially Joan Alcover (d. 1926) and Miquel Costa y Llobera, gave to Catalan poetry of the beginning of the 20th century an exquisite elegance.

The Catalan novel of the end of the 19th century and early 20th is represented by the names Narcís Oller, Joaquim Ruyra, Víctor Català (pseudonym of the authoress Catalina Albert i Paradís), and especially Eugeni d'Ors, author of *La ben plantada*. A younger generation includes the novelists Miquel Llor, Sebastià Juan Arbó, and the short-story writers J. E. Martínez Ferrando and Salvador Espriu. The theater suffered from overuse of the popular tone and routine ruralism. Nevertheless, worthy of note are Angel Guimerà (1849-1924), whose drama, *Terra baixa* (*Lowlands*), was an international success, and Josep Maria de Sagarra (b. 1894), important also as a lyric and epic poet and author of an excellent translation in verse of the *Divine Comedy*.

Perhaps one of the most significant events in the Catalan literature of the third decade of the 20th century was the surrealist manifesto called the *Full groc* (*Yellow Leaf*), one of whose signers was the painter Salvador Dalí. Published in 1928, it introduced the ideas of André Breton and was directed against the reactionary popularism of some Catalan authors of that period.

A rich personality characterizes Carles Riba (b. 1893), who as a poet, beginning with his *Estances*, renewed themes and images and carried the language to a lofty and serene dignity, values he maintained in his later books, among them

Salvatge cor (Savage Heart) published in 1952. Riba has exercised a decisive influence over younger generations of poets. Professor of Greek, Riba has made fine translations of the *Odyssey* (in long verse imitating the Homeric hexameter) as well as the work of Aeschylus, Sophocles, of Plutarch, and others. It should be realized that the most cultivated expression of modern Catalan prose is to be found in the translations and adaptations, nearly all of them excellent, of Greek and Latin authors that are published by the Fundació Bernat Metge, which numbers among its collaborators some of the finest Hellenists and Latinists.

The originality of the poetry of Josep V. Foix (b. 1894) is extraordinary. He has managed to join the more positive results of surrealism with a traditional Catalan inspiration (an echo of Raymond Lully and Ausiàs March), in a full form which is as well virile and bold and in an expression disturbingly metaphoric or consciously automatic. His book *Les irreals omegas (The Unreal Omegas)*, published in 1949, is one of the most important in the Catalan lyric of the first half of the 20th century. Other outstanding poets of this half century are Josep Carner, "Guerau de Liost" (pseudonym of Jaume Bofill i Mates), Joan Salvat Papasseit, Josep Maria López-Picó, Marià Manent, Tomàs Garcés, Sebastià Sánchez Juan, and the Majorcans Maria Antonia Salvà and Llorenç Ribet (the last named also an excellent writer of prose and fine translator of Latin authors).

The creation of multiple literary awards for the production of books in Catalan (City of Barcelona Prize for Catalan Poetry, established in 1951; Johanot Martorell Prize for the novel, in 1949), the legally sanctioned teaching of Catalan philology and literature in Spanish universities (laws of 1944 and 1952), the great increase in the editorial output in Catalan since 1947 (part of which is dedicated to the publication of medieval Catalan authors), these facts indicate that in the mid-20th century there has been a new resurgence of this literature in Catalonia proper and in Majorca, and, to a lesser degree, in Valencia; while in Roussillon (France) the literary production is scant and practically nothing is being published.

Rubió Balaguer, "Literatura catalana" in *Historia general de las literaturas hispánicas* (Barcelona 1949 and 1953).

MARTÍN DE RIQUER,

Professor of the University of Barcelona.

CATALANI, kă-tă-lă'ně, **Alfredo**, Italian composer: b. Lucca, Italy, July 19, 1854; d. Milan, Italy, Aug. 7, 1893. He was graduated at the Paris Conservatory and settled in Milan, where he achieved fame with brilliant operas, especially *Dejanice*, *Loreley*, and *Wally*.

CATALANI, kă-tă-lă'ně, **Angelica**, Italian singer: b. Senigallia, Italy, May 10, 1780 (although several other years are given); d. Paris, France, June 12, 1849. At the age of 12 she was sent to the convent of Santa Lucia at Gubbio, where her voice commanded attention. At 16 she was compelled by family misfortunes to turn her talents to account and made her first appearance on the stage at Venice. She continued with phenomenal success in leading soprano roles in the opera houses of Milan, Florence, Rome, Naples.

Madrid, Paris, London and the principal towns of Great Britain, in all of which her success and profits were immense. In 1814 she returned to Paris to take the management of the Italian opera there, but sustained thereby severe pecuniary losses from the injudicious interference of her husband, Valabrégue, formerly a captain in the French Army. On Napoleon's return in 1815 she was obliged to resign the direction of the opera, but resumed it again on the second restoration. In 1818 she again resigned the direction of the opera and subsequently made repeated professional tours through the Continent and Great Britain until 1828. In 1830 she retired from public life to a villa in the neighborhood of Florence; here she resided with her family and gave instruction to girls who manifested indications of local talent. She was a woman of majestic appearance and her voice displayed a wonderful degree of power, flexibility, and compass. She rather astonished and overpowered an audience by her marvelous execution rather than touching or subduing their hearts.

CATALAUNIAN PLAIN, the ancient name for the wide plain south of Châlons-sur-Marne, France, famous as the field where Aëtius, the Roman general, and Theodoric I, king of the Visigoths, gained a complete victory over Attila and the Huns in 451 A.D.

CATALCA, chă-täl-jä', or **CHATALJA**, town, Turkey, in Europe, 27 miles northwest of Istanbul. Cement and glass are manufactured, and it is famous for its watermelons. Here the Turks stopped the Bulgarian advance on Istanbul in the Balkan War in November 1912. As a result of the Treaty of Sèvres in 1920, Catalca marks the boundary of European Turkey and is therefore a center of heavy fortifications. Pop. (1950) 22,141.

CATALDI, kă-täl'dě, **Pietro Antonio**, Italian mathematician: b. Bologna, April 15, 1552; d. there, Feb. 11, 1626. He began his mathematical studies at the Academy of Design in Florence, was professor of mathematics at Perugia in 1572 and at Bologna in 1584. He is chiefly known as a pioneer in the use of continued fractions, the common form of which he invented (1613) and employed in the extraction of square roots. However, his method is more novel than practical and is far inferior to that of Cardan. He published more than 30 works on mathematics of which the most important is *Trattato del modo brevissimo di trovare la radice quadra delli numeri* . . . (Bologna 1613).

CATALDUS, Saint, the second bishop and patron saint of Taranto, Italy. He lived in the 6th century.

CATALEPSY, kăt'ă-lěp-sī, in medicine and psychology, a trance-like, morbid state of consciousness in which there is a loss of voluntary muscular control and a peculiar plastic rigidity of the muscles, which retain any position in which they are placed for an indefinite time. Artificially it can be induced by hypnotism; but frequently it is a symptom of hysteria (q.v.), dementia praecox (q.v.), catatonia (q.v.), and stuporous melancholia—all of which have much in common, being affections superimposed on the hysterical nervous organization, a type of make-up of a character, whose main features

are assuming a definite recognition by students of the functions of the nervous system. The normal functions of respiration, digestion and circulation continue. Prolonged cases demand forced feeding. Between attacks cold baths, tonics and various remedies are recommended. An emetic or a pinch of snuff may sometimes avert an attack. The disease still demands investigation, as its immediate cause is not known.

Consult Janet, Pierre, *Mental State of Hystericals* (Paris 1894); Dana, Charles Loomis, *Textbook of Nervous Diseases* (New York 1901); Ferraro, Armando, and Barrera, S. E., *Experimental Catalepsy* (Utica 1937); Cecil, Russell L., ed., *A Textbook of Medicine* (Philadelphia 1944).

CATALONIA, kăt-ă-lôn'yă; -lō'nī-ă (Spanish CATALUÑA, kă-tă-lōō'nyă; Catalan CATALUNYA, -lōō'nyă), a region of Spain, at one time a principality. Covering 12,431 square miles, and bounded on the east by the Mediterranean Sea, on the north by France, on the west by Aragon, and on the south by Valencia, it comprises the four provinces of Barcelona, Tarragona, Lérida, and Gerona. The 240-mile coastline on the Mediterranean has good harbors at its former capital, Barcelona (q.v.), and at Rosas, Palamós, Tarragona, and San Carlos de la Rápita. Other urban centers are Gerona, Mataró, Vich, Manresa, Sabadell, Tarrasa, Reus, and Tortosa.

Physiography.—The terrain is in general rugged. A spur of the Pyrenees extends through the region and in the northern part several peaks exceed 9,500 feet and form alpine-type valleys in which important rivers have their sources. In the northwest corner of the region is the *Valle de Arán* where the Garonne River has its source; in the center of the Pyrenean section is the Andorra valley and adjoining it, the Cerdaña, traversed by the Segre River. The Pyrenees descend to *Coll de Perthus*, the best of the passes in the chain, and meet the coast at Cape Creus. From the Pyrenees many minor chains descend to the south, such as Cadí, Montseny, Gabarras, Montsech, Montserrat, Llena, Montsant, and Prades, forming fertile valleys and connecting in the south with the Iberian mountain system. A plain opens to the northeast—the Ampurdán. In the southwest the tertiary basin of Lérida forms another plain which is very dry and linked geologically with Aragon.

Aside from the Ebro River—navigable in the lower part of its course—which receives the waters of the Spanish Pyrenees, the chief rivers in Catalonia are the Segre, the most important affluent of the Ebro, with its own affluents, the Noguera Pallaresa and the Noguera Ribagorçana; the Fluvià; the Ter; the Llobregat; and the Froncoli. Some form deltas, the largest being located in the mouth of the Ebro.

Along the Mediterranean coast southward, the peninsula of Cape Creus, its most eastern point, is followed by the Gulf of Rosas and Cape Bagur. Further south the magnificent rocky *costa brava*, leads to a succession of beaches and cliffs which extend to the delta of the Ebro River.

Agriculture and Industry.—The region of Catalonia is rich in agricultural products. In the mountainous areas cattle are raised and in the drier parts, goats and sheep. Cultivation is varied: grain, vine and olive fields cover a great part of the country and in the swampy zones of the deltas rice is grown. In the last hundred

years many industries have been developed. Chief among these are mining (iron, coal, potash, salt), metallurgy (see CATALAN FURNACE), paper mills, and in particular, textiles (cotton and wool). Because of its agricultural and industrial richness, Catalonia has become the first region of Spain. The Catalonians have been renowned as good traders throughout their history, and in the present century, they have developed a flourishing mercantile life.

History.—Through the centuries Catalonia has maintained a strong regional unity and its own language (see CATALAN LANGUAGE; CATALAN LITERATURE). Paleolithic man left his traces here in his migrations between glacial Europe and Africa and the fossil jaw of Bañolas is evidence of the early presence of Neanderthal man. The race which still forms the ethnic substratum of Spain arrived here in the Paleolithic period. During the Neolithic period invasions from the south brought people with new inventions (agriculture, pottery, metallurgy) from the Nile Valley, and from the north, people of eastern origin, who settled in the Pyrenees, becoming a pastoral race with a culture not wholly forgotten today.

The first Indo-Europeans arrived in the region about 1000 B.C. and two centuries later Celtic tribes intermixed with the indigenous population. Although it is doubtful whether the Phoenicians ever visited the Catalonian coast, it is probable that the Greeks (Rhodians) were early settlers. In the 6th century B.C., Phoenicians from Massalia (Marseille) founded a colony in the Gulf of Rosas, which they called Emporion (market). The site of Emporion has some of the most impressive archeological remains of the Greek settlements in the west, and its name survives in the name of the district of Ampurdán.

The Carthaginians under Hannibal attempted to master this region on their way to Italy; but a Roman army debarked at Emporion in 218 B.C. and after a prolonged struggle under Scipio succeeded in expelling the invaders in 206 B.C. In this war the native Iberians assisted the Romans against the Carthaginians, but subsequently fought for their independence from Rome until they were finally subjugated by Cato the Elder in 196 B.C. The country was soon Romanized and became prosperous. Roman authors describe the peoples of Catalonia as consisting of the *Ilergaones* in the south, the *Ilergetes* in the Segre plain, the *Cosetani* in Tarragona, the *Indigetes* in the Ampurdán, the *Ceretani* in the Pyrenees, and the *Ausetani*, *Laetani*, and *Lacetani* in the center. Tarraco (Tarragona) was the capital of the most important province of Roman Spain and many evidences of the Roman occupation still survive (temples, circus, theater, amphitheater, and aqueducts). Barcino (Barcelona) did not become important until after the 1st century A.D.

The decline of the Roman Empire and finally the invasion of the Visigoths put a check on the prosperity of the country. Barcelona became the capital of the Visigothic king, Ataulphus, who was murdered there in 415 A.D. Subsequently the Visigothic power passed to Toledo, and Catalonia preserved a Roman tradition until the Arab invasion in the early 8th century. Overrunning all but a few Pyrenean valleys, the Arabs moved across the Pyrenees into France, but in the last years of the century, the forces of Christianity liberated the Pyrenean region,

and, with the help of Charlemagne, the Saracens were driven out from Gerona and Barcelona.

After the formation of the *Marca Hispanica*, the Carolingian kings favored the independence of the counts of the *Marca*, and by the 12th century the counts of Barcelona had extended their holdings north of the Pyrenees. In 1137 Catalonia and Aragon were united by the marriage of Ramon Berenguer IV to Petronilla, daughter of the king of Aragon, thus further expanding the Catalonian power which was only curtailed north of the Pyrenees by the Battle of Muret in 1213.

The next two centuries were the most glorious for Catalonia; after many conflicts with the French kings as well as with the popes, both Sicily and Sardinia were annexed to the realm; Catalan knights invaded and ruled Athens and other Greek territories (see CATALAN GRAND COMPANY); and Naples came under the control of a Catalan dynasty. With the end of the Middle Ages, however, the opening of new trade routes caused Mediterranean trade to decline, and Catalonia to lose its dominant position as a trading center. The Aragon crown passed to a Castilian branch in 1410 and, after the marriage of Ferdinand of Aragon and Isabel of Castile in 1474, a united Spain soon developed imperial designs in America. The political and economic decadence of Catalonia began at this time.

In 1640, during the reign of Philip IV, Catalonia revolted with the help of King Louis XIII of France. During the reign of Louis XIV, by terms of the Treaty of the Pyrenees (1659), Roussillon was detached and incorporated in the kingdom of France. In the War of the Spanish Succession, it took a stand against Philip V and after a fierce resistance, Barcelona was captured (1714) and all the privileges of home government were suppressed.

During the 18th century Catalonia developed economically and became in time the richest of the Spanish regions. It fought gallantly in the wars against Napoleon (Siege of Gerona, 1808) and in the numerous internal conflicts during the 19th century.

In the 20th century, anarchistic and national movements developed side by side. Agitation for home rule led to the establishment of an autonomous government in 1932, and two years later an unsuccessful revolution was spurred by extremists. During the civil war of 1936–1939 Catalonia suffered severely, being for the most part on the republican side. In February 1939 Catalonia was reincorporated in united Spain by General Franco's army which included many Catalan contingents. Pop. (1950) 3,240,313.

LUIS PERICOT.

CATALPA, ká-tál'pá, a genus of trees of the family Bignoniaceae, consisting of about 10 species in North America and Asia. They have large, entire or lobed leaves, large panicles of showy white, yellow or pink flowers, and fruit of long, slender, cylindrical pods. *C. catalpa*, the common catalpa or Indian bean, is a native of the southern United States. *C. speciosa*, a similar species, the western catalpa, ranges from Illinois and Indiana to Louisiana and Mississippi.

The wood of these two species is coarse-grained and soft but very durable in the ground, consequently it is much valued for fence posts and railroad ties. These species and some of the Asiatic ones are very widely used as shade trees.

CATALYSIS, or **CATALYTIC ACTION** (Gr. *Katalyein*, to dissolve) an acceleration of the rate of a chemical action due to the pressure of a small quantity of a substance (the catalyst) which remains unchanged at the end of the reaction. For example, cane sugar is inverted (changed into a mixture of dextrose and levulose) in the presence of acids with a velocity that increased with the strength of the acid. This phenomenon is called catalysis, and the acid is said to be a catalyst. Water, which delays the reaction, is said to be a negative catalyst. Again, it is possible by the formation of an arc under water to obtain ultramicroscopic suspensions of many of the metals, such as gold, silver or platinum. These suspensions have the remarkable property of decomposing hydrogen peroxide very rapidly into water and oxygen, while they themselves remain unchanged.

A similar action is shown by certain organic substances, the enzymes. In the case both of the enzymes and of the ultramicroscopic colloidal metallic suspensions, the catalytic action is immensely diminished by the presence of very slight quantities of certain poisonous substances such as hydrocyanic acid or hydrogen sulphide. Another interesting example of catalysis is the action of platinum—black or sulphur dioxide and oxygen, which unite in its presence to form sulphur trioxide. Water vapor is often a catalytic agent; dry ammonia vapor and dry hydrochloric acid will not unite. This example illustrates the fact that catalytic agents accelerate both halves of a reversible reaction, for dry ammonium chloride can be vaporized without dissociating into ammonia and hydrochloric acid.

Catalysis is an extremely common phenomenon in chemistry. Its nature is not well understood; it is agreed that in certain reactions which appear catalytic the "catalyser" enters into the reaction and is ultimately regenerated, but this explanation does not cover all the cases found. In the case of platinum black, which acts as a catalyser in many reactions, Faraday considered that the action was due to the approximation of the molecules of absorbed gases. This case, however, has also been explained as due to the formation of intermediate products into which platinum enters. See also CHEMISTRY—*Catalysts*; ENZYMES.

CATAMARAN, kät-à-mà-rän', a kind of raft used in the East Indies, Brazil, and elsewhere. Those of the island of Ceylon, of Madras, and other parts of the Indian coast are formed of three logs. These are secured together by means of three spreaders and cross lashings through small holes. The center log is much the largest, is pointed at the fore end, and above it are lashed the two others to form a hollow for the crew and cargo, the center log acting as keel.

The name is also applied to any double-hulled craft, many of which have been built for experimental and recreational purposes.

CATAMARCA, kät-à-mär'ká, province, Argentina, a mountainous region in the Andes covering 45,829 square miles, next to the Chilean border. A salt desert. *Salar de Antofalla*, extends about 100 miles along the western foot of Sierra de Calalaste, at an altitude of 11,350 feet. The main rivers are the Santa María, the Belén, and the Colorado, and since every valley has its

mountain stream, the whole province is well watered. Most of the smaller streams are dry in the summer, but overflow in the winter. There are also a number of salt lakes. The soil is fertile, producing large crops of maize and wheat and supporting large numbers of livestock, especially goats. The vine is also cultivated and yields wine and spirits which bear a high name in the surrounding countries. The principal exports are beasts of burden, horned cattle and hides and goatskins, raw or tanned. The principal mineral is iron, but gold, silver, and lead are also found. The capital is Catamarca. Pop. (1943) 162,115, chiefly of Indian extraction, with a considerable mixture of Spaniards.

CATAMARCA, Argentina, the capital of the province of Catamarca, situated on the Valle River, 82 miles northeast of La Rioja and about 250 miles northwest of Cordoba. It is connected by rail with La Rioja and all the chief towns of the republic. It is regularly and moderately well built and contains a fine town hall, a Franciscan monastery, a national college, and a normal school for women. There are considerable imports of European goods and the place is the center of distribution for a flourishing district. Dried figs, wines, brandy, and cotton are the principal articles of export, together with the curious form of embroidery for which the women are celebrated. The city is a mining and agricultural center. It was founded in 1683. Pop. 22,000.

CATAMOUNT, a short form of the phrase "cat of the mountain," frequently found in the older books about America and still occasionally used as a name for the lynx of the eastern United States, and sometimes for the puma, or panther, once common in New England. The term is so indefinite that it is well that it has fallen into disuse.

CATANDUANES, kă-tăn-dwă'nās, island, Philippine Republic, lying northeast of the province of Albay, Luzon, with which it was administratively connected as a subprovince until organized as the republic's 50th province (1947). Its length is 44 miles north and south; width, 29 miles at the southern end; area, 704 square miles. The mountain system consists of three ranges that radiate from Mount Cantilamo near the center of the island; the rest of the surface is irregular, with low hills. The most important rivers are the Oco and the Bató or Cabugao; there are also a number of smaller rivers and the island is well watered. Its soil is fertile, and rice, cotton, corn, and hemp are raised; indigo and coconuts are exported. Gold is found in the gravel beds of some of the rivers. The capital and largest town is Virac (pop. 22,000). The governor and one congressman are elected by the people. Pop. 120,000.

CATANIA, kă-tăn'ya, (ancient CATANA), city, Italy, in the province of Catania, Sicily, on the borders of the valley of Noto. It is the see of a bishop, the suffragan of Monreale, 47 miles south-southwest of Messina, 85 east-southeast of Palermo. It is situated on a gulf of the Mediterranean, at the foot of Mount Etna. This city has been repeatedly visited by violent earthquakes, and partially laid in ruins by lava from eruptions of Mount Etna. The most disastrous eruption

was that of 1669, by which many of the antiquities of Catania were overwhelmed, and the worst earthquake was that of 1693 when 18,000 people were destroyed. Although again greatly injured by the earthquake of 1783, Catania is now reviving with great splendor and has much more the features of a metropolis than Palermo. The principal streets are wide and well paved with lava. Most of the edifices have an air of magnificence unknown in other parts of the island, and the town has a title to rank among the elegant cities of Europe. An obelisk of red granite, placed on the back of an antique elephant of touchstone, stands in the center of the great square, which is formed by the town hall, seminary, and cathedral. The cathedral, a fine building, was founded in 1091 by Count Roger, but required to be mostly rebuilt after the earthquake of 1693. It is dedicated to Saint Agatha, the patroness of the city. The suppressed Benedictine monastery of Saint Nicholas, comprising a church (with splendid organ), library, museum and other extensive buildings, was long celebrated for wealth and splendor. The university, founded about 1444, has about 1,200 students, a school of pharmacy, a library of over 130,000 volumes and a fine collection of shells. The ruins of the amphitheater, which was more extensive than the Coliseum at Rome, are still to be seen, as are also the remains of the theater, baths, aqueducts, sepulchral chambers, hippodrome, and several temples. The industries include the manufacture of silk, linen, and cotton goods, and objects in lava, wood, marble, and Sicilian amber, and the mining of sulphur. The harbor was formerly a good one, but by the eruption of 1669 its entrance was almost entirely choked up, and it is only in recent times that it has been improved, a considerable amount of money having been spent on it. The trade of Catania is of some importance, the principal export being sulphur, next to which come oranges and lemons, almonds and other fruits and wine. Cereals, textiles, and other manufactures are the chief imports. The exports have an average annual value of about \$5,000,000. A circular railway runs from Catania round the base of Mount Etna. The classic Catana was founded by Greeks from Chalcis about 729 B.C. and soon became prosperous. It was the Athenian headquarters in the war between Athens and Syracuse 432 B.C. It flourished under the Romans, by whom it was taken in 263 B.C. It was plundered by the Saracens and fortified by the Normans and, in 1169 A.D., almost destroyed by an earthquake. It was restored in 1232 and fortified by Frederick II, and again flourished for four centuries until the great earthquake and eruption of 1669. Pop. (1936) 244,972.

CATANZARO, kă-tăn-dzā'rō, (ancient CATACIUM), city, Italy, capital of the southern province of the same name, on a height, eight miles from the Gulf of Squillace. It suffered severely from the great earthquake of 1783, but is still a place of some importance, defended by a citadel, and containing a cathedral and various other churches, an academy of sciences, one of the four great civil courts of the kingdom, a lyceum, and three hospitals. The climate being cool and healthful in summer, many wealthy families reside here. The manufactures consist chiefly of silk and velvet,

and there is some trade in wheat, wine, and oil, Pop. (1931) 41,888 (commune); 26,976 (town).

CATAPULT, an engine of war, which had considerable vogue among the ancients. It somewhat resembled a crossbow, and was operated by means of a string or rope, suddenly freed from great tension, which gave a powerful impulse to an arrow placed in a groove. There were various modifications of catapults, but in essential purpose and construction they were all alike. Thus, there were catapults fixed upon a scaffold with wheels, which were used for hurling huge stones in sieges; smaller machines that were readily portable were employed in field operations.

In *acronautics*, a device, such as a truck accelerated on a track by a powerful springs or by the explosion of powder, for launching an airplane at flying speed from the deck of a ship.

CATARACT. The name given to an opaque condition of the crystalline lens of the eye or its capsule. Although recognized from ancient times as a cause of blindness there is little in literature to suggest that early civilizations, as for example the Egyptians, appreciated its real nature. Probably the first to demonstrate the true nature of the condition was Michel Brisseau (1676-1743) who published his observations in 1709. Jacques Daviel (1693-1762) of Paris had the honor of originating the modern treatment of extraction of the lens (1755). Samuel Sharp (1700-1778) of London was first to use the modern cataract knife. Up to the time of Albrecht von Graefe (1828-1870) of Berlin, who achieved phenomenal success in cataract operations, the loss of eyesight in surgical treatment had been about 10 per cent. This was lowered by von Graefe to a little over 2 per cent. The next great advance in the cataract operation was made by Henry Smith of the Indian Medical Service, of Jullundur, India, who perfected his operation of extraction of the cataract within the capsule, one of the most important innovations of modern ophthalmic surgery (1900-1901).

The opaque cataract lies behind the cornea and is not to be confused with an opacity of the cornea, by those unfamiliar with the disease. Cataracts are divided into several classes, the simplest division being into primary and secondary. Primary cataracts develop independent of any other disease, such as diabetes for example. Under these are classed cataracts occurring in young persons (juvenile) or in old persons (senile). Secondary cataracts may develop in the course of diabetes, or from injury (traumatic). Cataracts are also classed as partial or complete the latter involving all of the lens. The condition is painless, being characterized only by gradual loss of vision although the sensation of light persists.

Treatment.—Traumatic cataract due to perforation of the lens may present a complete opacity which is often recovered from without operation, leaving perhaps slight cloudiness with little interference to vision. In some cases surgical measures are necessary for absorption to take place. Senile cataract is the commonest variety and the most important. It occurs generally in persons over 50 and may be several years in developing. Eventually the fluid portion of the lens is absorbed leaving an opaque substance which on further solidification separates easily from the capsule. This marks the stage of ripening, or the point beyond which further delay in operating is unnecessary. The classic operation consists in opening the cornea along nearly half its circumference, with or with-

out removing a portion of the iris, after which the lens is expelled by pressure. After a considerable period, special reading glasses of high refractive power are supplied to take the place of the lens which has been removed. Senile cataracts are generally bilateral but progress at different rates so that one is usually ready for operation before the other. At present the percentage of cases in which useful vision is restored by operation, followed by suitable training and proper glasses, is very large.

HAROLD W. JONES.

CATARACTS, a waterfall, one of the names given to sudden descents in streams of water, the more general English term being fall or falls. A considerable declivity in the bed of a river produces rapids. When it shoots over a precipice it forms a cataract. If it falls from steep to steep, in successive cataracts, it is often called a cascade. In rocky countries rivers abound in falls and rapids. In alluvial districts, falls, of course, are very rare. Rapids and cataracts are often a blessing to rugged countries, since they furnish the cheapest means of driving machines in manufactories. Waterfalls are also utilized in the furnishing of electric power in addition to ordinary water power. Many cataracts are remarkable for their sublimity. Among the grandest and most picturesque in North America is Niagara Falls on the Niagara River dividing Canada and the United States.

The Montmorency River, which joins the Saint Lawrence a few miles below Quebec, forms a magnificent cataract, 250 feet high. The Missouri, in the upper part of its course, descends 357 feet in 16½ miles. There are four cataracts, one of 87, one of 19, one of 47 and one of 26 feet high. The Yosemite River in California forms a series of magnificent falls, with a total descent of 2,600 feet. The first of them is a plunge of 1,500 feet, and is followed, after a series of beautiful cascades, by a final plunge of about 400 feet. Fully 200 miles from the mouth of the Hamilton River in Labrador there is a magnificent series of cataracts known as the Grand Falls, the largest having a height of over 300 feet. In Colombia, South America, a great cataract, that of Tequendama, is formed by the Bogotá River. The river precipitates itself through a narrow chasm, about 36 feet broad, to the depth of over 600 feet. On the Potaro River in British Guiana, the Kaieteur Fall, 740 feet high, and about 370 broad, is a splendid spectacle, and just below it is a second fall of 88 feet.

The most remarkable waterfall in Africa is one with which Dr. Livingstone's missionary travels first made us acquainted. This is a cataract on the Zambesi, called by the natives Mosioatunya ("smoke sounds here"), named by him Victoria Falls. The stream, about 1,860 yards broad, flowing over a bed of basaltic rock, is suddenly precipitated into a tremendous fissure, extending across the bed of the river from the right to the left bank, to the depth of about 370 feet. The breadth of this fissure or crack is only from 80 to 90 yards, and the pent-up waters, from which immense columns of vapor are continually ascending, are then hurried through a prolongation of the chasm to the left with furious violence. The so-called Cataracts of the Nile are not, properly speaking, cataracts. A more correct designation for them would be rapids. The Stanley Falls on the Congo comprise seven cataracts. On the Tugela River in Natal there are the Tugela Falls. On the Umgeni River,

in the same country, are the falls of the Umgeni (364 feet) and the Karkloof Falls (350 feet). There seem to be no waterfalls of more note in Asia than those of the Cauvery (Kaveri) River of India (320 feet).

One of the most striking falls in Europe is the Vettis in Norway. The height of the cataract is 850 feet. In Sweden, on the Göta River, a few miles below its outlet from Lake Vänern, are the celebrated falls of Trollhättan, which have a height of 108 feet. The cascade of Gavarnie, in the Pyrenees, is reputed the loftiest in Europe, being 1,385 feet high. Its volume of water, however, is so small that it is converted into spray before reaching the bottom of the fall. Another waterfall in the Pyrenees is that of Seculėjo, in the neighborhood of Bagnères de Luchon. It descends from the Lac d'Espingo, into the Lac de Seculėjo, or d'Oo, a singularly romantic mountain reservoir, from a height of 820 feet, and is the most copious of the Pyrenean waterfalls. The Swiss Alps likewise contain some falls of great sublimity. At Lauterbrunnen, in addition to numerous other cascades, is the renowned Staubbach Fall, about 1,000 feet high, which, however, from its small volume of water, has none of the terrific adjuncts of a cataract, and resembles, in front, a beautiful lace veil suspended from the summit of the precipice. Near Martigny is the picturesque waterfall of Pissevache, the cascade being 215 feet high. The Falls of the Rhine near Schaffhausen are renowned over Europe. The Rheinfall is 370 feet broad and 100 feet high. In Italy the falls of Terni, or the Cascata delle Marmore on the Velino, have been immortalized by Lord Byron, and, though artificial, are justly regarded as among the finest and most picturesque in Europe. They consist of three falls, the aggregate height of which may be estimated at 650 feet. The falls of the Aniene or Teverone, near Tivoli, are likewise very beautiful. They, too, are artificial, and have a fall of about 80 feet. See also **WATERFALL**.

CATARMAN, kä-tär-män', municipality, Philippine Islands, on the north coast of the island of Samar, situated on the Catarman River, 55 miles north-northeast of Catbalogan. It has a good anchorage ground. In 1871 the town was destroyed by a volcano which burst forth in July from low land on the west side of the island, and in two months had thrown up a hill two-thirds of a mile long, one third of a mile wide and about 450 feet high, destroying all vegetation for miles around. At the time of the visit of the *Challenger*, January 1875, the volcano had attained a height of 1,950 feet, and was still active, there being visible columns of smoke by day and series of small fires at its summit by night. Pop. (1948) 33,153.

CATARRH, kä-tär', a term once in common medical usage to designate inflammations of mucous membranes, in particular those of the nose, throat, and air passages, and accompanied by a discharge or exudate. In modern medical teaching the term is practically abandoned except to indicate occasionally the consistency of a mucous discharge and to distinguish it from one that is frankly purulent. At best it is inexact, and therefore useless to the study of pathology.

CATASAUQUA, borough, Pennsylvania, Lehigh County, altitude 342 feet, on the Lehigh

River, and located on and served by the Jersey Central, the Lehigh Valley, and the Lehigh and New England railroads, and the Reading System, three miles north of Allentown. Anthracite pig iron was made here about 1839. Catasauqua has textile factories, cement works, foundry and machine shops, and flour mills. Incorporated as a village in 1736, it became a borough in 1853. Here is the home of George Taylor (1716-1781), signer of the Declaration of Independence. Burgess and council government. Pop. (1950) 4,923.

CATATONIA, a phase of dementia precox (schizophrenia) in which the individual lacks the will to talk or to move, stands or sits in one position, assumes fixed postures, and resists attempts to activate motion or to elicit speech. Once regarded as a muscular phenomenon, it is now applied to certain types of maniacal outbursts. It is present in many psychoses but is best observed in dementia precox, constituting about 10 per cent of all cases. The stupor is usually of a harmless character, but may be succeeded by a violent outburst in which panic and hallucinations are manifest. In this stage the patient may be dangerous to those about him. Physically, the mental disorder is extremely exhausting. Those afflicted may remain in a strained position for hours, days, or even longer. Instances are known in which a patient has lain rigid in bed for as long as a year without taking any notice of what has gone on about him. Such a case was described most dramatically in one of Guy de Maupassant's stories.

Urination and defecation may take place in bed and food may have to be given through a tube. Two types of catatonia are distinguishable: (1) catatonic stupor in which immobility and mutism are the prominent features; (2) catatonic excitement, in which the patient makes incessant stereotyped movements, walking to and fro within his room or going through the motions of a trade or occupation. He may talk without ceasing, repeating a meaningless jargon over and over, hour after hour. In the most violent forms, the individual may become extremely destructive, making wild dashes and attempting to break everything within reach. If unsuccessful in reducing furniture to bits he may attack with his fists the walls or bars of his room and if not restrained he may be injured. He may even kill anyone who crosses his path. Since he is inaccessible mentally he may be thought to have a completely blank mind. Nevertheless if such a patient recovers from the delirium he may be able to give an intelligent account of what happened and of what was said to him. In general, the chief difficulty of the individual is his inability to make adjustments to the demands of society and especially to those of a normal love life. This incapacity is revealed in distorted behavior which reflects internal conflict. For the most part those who manifest well-developed catatonia of the maniacal type, and who exhibit symptoms for a number of years, are fit subjects for confinement in an institution where proper restraint may be imposed. HAROLD WELLINGTON JONES, M.D.
Editor, "Blakiston's New Gould Medical Dictionary."

CATAWBA, ká-tó'ba, a light and sparkling American wine. See WINE AND WINE MAKING.

CATAWBA RIVER. See WATEREE.

CATAWBAS, a tribe of Indians of the great Siouan family, formerly living on the Catawba River in the Carolinas. They were noted for their courage in fighting the Cherokees, the Iroquois, and the "French Indians" from north of the Ohio; and for their fidelity to the English and later the American interest. Numbering probably 5,000 in 1600, the tribe dwindled through war and epidemics. A few joined the North Carolina Cherokees; others joined the Creeks and Choctaws in Oklahoma; and some, converted to Mormonism, settled in Utah and Colorado. A remnant remains on a small reservation in South Carolina.

Consult Milling, Chapman J., *Red Carolinians* (Chapel Hill 1940); Wright, Muriel H., *A Guide to the Indian Tribes of Oklahoma* (Norman, Okla., 1951).

ANGIE DEBO,
Oklahoma Agricultural and Mechanical College.

CATBALOGAN, kät-bä-lô'gän, municipality, Philippines, capital of the Province of Samar. It is situated on the west coast of Samar Island. A bay at the mouth of the Antigas River, protected by small islands, provides a fair harbor. A trading center for an agricultural area producing rice, hemp, and coconut, its chief exports are copra and hemp. Pop. (1948) 26,839.

CATBIRD, a common songbird (*Dumetella carolinensis*), found in the eastern two thirds of North America and in Bermuda. It receives its name from its mewing catlike alarm note. Related to the mockingbird and brown thrasher, it is an accomplished singer as well as a mimic. The song is bright and varied but somewhat disjointed, melodious notes being intermixed with harsh and squeaky ones. About 10 inches long, it is a trim and slender slate gray bird with blackish crown and a touch of chestnut beneath the tail. The catbird lives in bushes or hedges sometimes in close proximity to residences. The nest of stems and rootlets is well concealed in a bush or dense hedge usually only a few feet above the ground. Four or five dark grayish blue eggs are laid. The old birds scold very aggressively when the nest is approached; at other times the catbird is lively and inquisitive. The catbird feeds upon insects and berries, and is migratory in the northern parts of its range, travelling chiefly at night.

In Australia the name catbird is applied to one of the bower birds (*Ailuroedus crassirostris*), which, like the American catbird, has a mewing cry.

DEAN AMADON.

CATCH, a term applied to the English musical rounds of the 17th and 18th centuries. They were in effect short canons, with each part repeating the phrase another has just sung. The first collection of catches to be published was *Pammelia* (1609), and the most famous was John Hilton's *Catch as Catch Can* (1652-1658). Generally the words sung to the catches were humorous and during the Restoration some were notoriously indecent. The English composer Henry Purcell has numerous catches among his works, and in 1761 a Catch Club was founded in London. Its members, including often royalty, composed or played glees and canons besides catches.

CATCHFLY, the common name for several plants of the family Caryophyllaceae that are characterized by a sticky exudation of the flowers or stems that is presumed to trap insects. Species of the genus *Lychnis* and of the closely related genus *Silene* in particular are called catchflies, but both also have the common name of campion. The German catchfly is *Lychnis viscaria* (sometimes separated into the genus *Viscaria*). Occasionally the Venus flytrap is called Carolina catchfly.

CATEAU, Le. See LE CATEAU.

CATECHESIS, kät-ê-kê'sis (from the Greek *katechiso*, to teach by word of mouth), is applied to the body of Christian truths and precepts which was taught to prospective converts in the early church. Catechization during approximately the first six centuries of Christianity was essentially concerned with the preparation of adults for reception of baptism. It was an initiation into the mysteries of the Christian religion. Early catechesis is best illustrated in the discourses of Peter and Philip (Acts 2:4-36; 8:35-38), and by the preaching of Paul (Acts 17:22-31). Cyril of Jerusalem has left us a remarkable example of patristic catechesis consisting of 24 lectures delivered to aspirants for baptism. By the medieval period it became embodied in formal texts of Christian doctrine, and of such is the content of our modern catechism.

CATECHETICAL SCHOOLS, kät-ê-kê't'i-käl, were institutions for the elementary education of Christian teachers, of which there were many in the Eastern Church from the 2nd to the 5th century. They were different from catechumenical schools, which were attached to almost every church and which were intended only for the instruction of proselytes and children. The catechetical schools, born from the conflict of Christian doctrine with Greek philosophy, were intended to provide a knowledge of Christianity.

The first and most renowned was established about 175 for the Egyptian Church at Alexandria, on the model of the famous schools of Greek learning there. Teachers such as Pantaenus, Clement, and Origen gave them splendor and secured their permanence. They combined instruction in rhetoric, oratory, music, literature, and philosophy, with the principal branches of the theological study, exegesis, the doctrines of religion, and the traditions of the church; distinguished the popular religious belief from the gnosis, or the thorough knowledge of religion; established Christian theology as a science; but, by blending Greek speculations and gnostic phantasies with doctrines of the church and by an allegorical interpretation of the Bible, they contributed to the introduction of heresies. The distraction of the Alexandrian Church by the Arian controversies caused the destruction of its catechetical school c.336.

The catechetical school at Antioch appears not to have been a permanent institution like the Alexandrian, but only to have been formed around distinguished teachers, when there happened to be any in that city. Although some famous men taught in Antioch about 220, we have no certain information of the theological teachers there, such as Lucian, Diodore of Tarsus, and Theodore of Mopsuestia, until the latter part of the 4th century. These teachers were distinguished from the Alexandrians by more sober views of Chris-

tianity, by confining themselves to the literal interpretation of the Bible, by a cautious use of the types of the Old Testament, and by a bolder discussion of doctrines. The Nestorian and Eutychian controversies in the 5th century caused the ruin of the school at Antioch.

Of a similar character was the school instituted at Edessa in 363 and closed in 489, and the school afterwards established at Nisibis by the Nestorians in its stead.

To these schools succeeded, at a later date, cathedral and monastic schools, especially among the western Christians, who, as late as the 6th century, were educated in heathen schools and never had established catechetical schools except possibly at Rome.

P. R. COLEMAN-NORTON.

CATECHISM, kăt'ê-kîz-m (from the Greek *katechesis*), applied originally to religious instruction given orally, has come in modern usage to refer to a treatise in the form of question and answer planned for teaching the elements of religion. In the early Church religious instruction was developed during the period of the catechumenate as to texts and method in the famed catechetical schools of Alexandria, Antioch, Jerusalem, and Rome. The fathers of the church, among them Clement of Alexandria, Origen, and Cyril of Jerusalem, have left us examples of their teaching which are in effect brief compendiums of Christian doctrine. A precise methodology for use in expounding religion to candidates for baptism was the subject of Augustine's treatise *First Catechetical Instruction* (*De catechizandis rudibus*), which appeared c.405 A.D. This work, which exerted a profound influence on subsequent catechetical method, contained three "lectures" graded to the capacity of three different classes of pupils. The subject matter of the catechetical teaching from the early beginnings of the church was divided according to the four major headings: the Apostles' Creed, the Ten Commandments, the Sacraments, and Prayer. This division of the entire field of Christian doctrine still prevails in practically all modern catechisms of the Christian churches.

Since the time of Martin Luther, the term "catechism" has been used to designate a compendium of Christian doctrine for children and youth that is arranged in the form of question and answer. The question and answer form of religion text was in use much earlier. The first manual resembling our modern catechism that is extant is a treatise by Alcuin or a member of his school at Aachen and is dated about the year 800. The title of this work is *Disputatio puerorum per interrogationes et responses*. It is an extensive explanation of Christian truths from the creation to the Lord's Prayer. The 16th century witnessed the publication, made possible by the invention of printing, of a large number of catechisms both with and without the question and answer form. Luther brought out his *Primer of Religion* in 1520 and his *Smaller Catechism* appeared in 1529, followed shortly afterwards by his *Larger Catechism* intended for the clergy and schoolteachers. The latter two works were arranged in questions and answers. The catechism of John Calvin for children was published in 1537, and an Anglican catechism was printed with the first *Book of Common Prayer* in 1549. Graded catechism became the rule: for beginners, for youth, and an advanced text for adults and teachers. The

Shorter Catechism used by Presbyterians was printed and adopted in 1648. St. Peter Canisius published the first popular Catholic catechism in three grades in 1555 and the catechism of St. Robert Bellarmine appeared in 1597. The newly defined doctrines of the Council of Trent (See TRENT, COUNCIL OF) were incorporated in what has been known as the *Catechism of the Council of Trent* which was published without the question-answer arrangement in 1565.

The catechism today retains its place as a basic text for teaching the tenets of the various faiths. No longer merely a formal exposition of truths and practices, it is graded and tested as to vocabulary range to fit the age and learning capacity of children and youth. It is embellished with pictures and apt illustrations together with such study aids as exercises, cases of conscience, and tests. Recent development of audio-visualization has brought about widespread use of catechetical films, both motion pictures and slide films, incorporating in whole or in part the content of the catechism.

JOSEPH B. COLLINS,
Director, Confraternity of Christian Doctrine,
National Center, Washington, D.C.

CATECHU, kăt'ê-chōō, the extract prepared from the wood of some trees of the West Indies, especially from the *Acacia catechu*. It is used in dyeing and tanning; also in medicine as a powerful astringent. Catechu, usually sold in solid form, can be dissolved in hot water or alcohol. It contains about 25 per cent catechutannic acid, the main factor of its effectiveness.

CATECHUMEN, kăt'ê-kū'mĕn (from Greek *katechoumenos*, instructed), is the name applied during the early centuries of the church to one undergoing instruction in Christian belief and precept. The word appears in Galatians 6:6. The system of instruction and discipline which gradually developed for reception of converts from paganism was called the catechumenate. Since apostolic times there had been a practice of preparing individuals for admission into the Christian community by a preliminary instruction. This can be seen in the informal teaching and preaching of the apostles as found in the Acts. By the end of the 2d century the catechumenate was well established, and reached its highest point of effectiveness during the two following centuries. The period of probation or initiation into the Christian mysteries varied in length for different communities. It consisted of two classes: the catechumens, properly so called, or *audientes* (listeners); and the competents or elect, that is, those seeking or chosen for reception of baptism. The neophytes or those who had completed their preparation and were baptized are improperly included as a third category of the catechumenate.

The adult who expressed a desire to become a Christian was subjected to a kind of novitiate which included instruction on the doctrines of the church, its moral precepts, and its life of prayer; hence it was an intellectual, moral, and ascetical education. Cyril of Jerusalem has left us a series of 24 lectures which he delivered to catechumens and neophytes in the middle of the 4th century, and the technical pedagogy of the catechists in preparing catechumens is illustrated in the famed treatise of Augustine called the *First Catechetical Instruction* (*De catechizandis rudibus*).

The catechumens were not bound by the

Christian rule of life in all its full severity, but they were outwardly associated with and enjoyed all the privileges of the Christian community. They participated in most of its services, although only in that part of the Mass which included the opening ceremonies and the sermon, called the Mass of the catechumens. They were not permitted to be present for the recital of the Creed and the solemn canon of the Mass with the reception of the Eucharist. All this was a remote preparation for baptism; and a prospective convert could remain in this state as long as he desired. Sometimes a catechumen remained for years, even to the end of his life, with only a formal desire to become a Christian in order to benefit at the last possible hour by the baptismal absolution of all his sins. The Emperor Constantine remained a catechumen until his deathbed baptism.

If a catechumen decided to complete his period of preparation and the church authorities approved his motives and qualifications, he gave his name to the local pastor and he was formally enrolled among the "competents." A rigorous period of instruction was then begun which usually took place during Lent. It included explanations of the Creed and the Lord's Prayer as well as the principal duties of a Christian. An examination, called the scrutiny, was held around the end of Lent and the elaborate ceremonies of baptism were held on the vigil of Easter or in some places on the vigil of Pentecost. The newly baptized neophyte was clothed in a white garment, a sign of purity of soul, the Sacrament of Confirmation was solemnly administered, and he partook of the Holy Eucharist for the first time—all on Easter morn.

The custom of admitting children to baptism and the necessity of receiving large numbers of individuals into the church after the onset of the barbarian invasions caused a gradual decline of the discipline of the catechumenate; its disappearance in most places was marked by the end of the 5th century. It remains today only in vestiges of the rite of baptism and reception into the church as found in the ritual of the Christian church.

JOSEPH B. COLLINS,
*Director, Confraternity of Christian Doctrine,
National Center, Washington, D.C.*

CATEGORICAL. In traditional logic, a statement is called categorical if it makes a single assertion, unconditionally and without alternatives. Thus "Columbus discovered America" is a categorical statement as distinguished from such hypothetical statements as "If the Norse did not arrive first, Columbus discovered America" and the disjunctive statement "Either the Norse discovered America or Columbus did." As may be seen from these illustrations, hypothetical and disjunctive statements contain components which are categorical. In this sense, also, a syllogism is called categorical if its premises and conclusion are categorical statements.

Kant made use of this notion in ethics by dividing injunctions to act, or *imperatives* as he called them, into hypothetical and categorical. A hypothetical imperative gives a command conditionally, on the assumption of a certain aim or purpose. Thus "If you wish to arrive on time, hurry!" is a hypothetical imperative and has no force for one who does not wish to be on time. Such imperatives can never form the basis of a universal ethics since the injunction can be escaped by deny-

ing the aim stated in the condition. If there is to be any ethic binding on all rational beings it must, Kant argues, be based on a categorical imperative, i.e., one without conditions. Kant claims there is such an imperative most frequently stated as follows: "So act that you could will the maxim of your action to be a universal law." The maxim here is simply the principle on which a person acts and the force of the injunction is to claim that one should act when and only when he could wish that the principle of his action be adopted universally. This command is unconditionally binding and so is categorical.

PAUL HENLE.

CATEGORY. In the philosophy of Aristotle, categories represent the ultimate types of being. Thus one may say of something that it is a chair, of a chair that it is a piece of furniture, of a piece of furniture that it is an artifact, and so on going to broader and broader characterization until one comes to substance. Here one can give no broader description, hence substance is a category. In a similar fashion one may say of red that it is a color, of color that it is a quality, and here one stops; hence quality is a category. Aristotle gives varying lists of categories, the most complete in the *Categories* includes: substance, quantity, quality, relation, space, time, situation, state, action and passion (being acted on). Situation is differentiated from place in that it refers to such characteristics as being right side up or upside down rather than merely giving a location. Similarly state (for example, is shod) differs from quality (for example, is red) in applying most specifically to one part of a whole.

Aristotle's treatment of the categories strikingly differentiates substance from the other categories. It is distinguished from them principally by not being in anything else (that is, not being a characteristic of anything else) and by its ability to take on contrary characteristics. Thus a chair may have its color changed without ceasing to be that chair, but nothing falling under one of the other categories can undergo similar change. Substance, moreover, is divided into two sorts: *primary substance* or individual things (for example, individual men or chairs) and *secondary substances* (for example, the species, man, or the type, chair). Primary substances may only be subjects of discourse and may never be predicated of anything. Secondary substances may be predicated of primary (for example, one may predicate "man" of Socrates, but one cannot predicate Socrates of anything).

Kant also made use of the term "category" in reference to a different problem. The British philosophers of the Enlightenment, from Bacon through Hume, had tried to show that knowledge derives entirely from experience. The attempt was a failure and, in Hume's development, the result was skepticism. Kant accepted Hume's reasoning, agreed that if experience were the only source of knowledge the result would be skeptical, but argued, since there is knowledge, it must have some source in addition to experience. This source he found in certain forms of perception and in certain concepts by means of which we organize our experience. These concepts he called "categories."

A parallel to Kant's general view of the categories is given by some contemporary accounts of the influence of needs and mental sets upon perception. It is generally admitted that per-

ception is not a simple recording of effects upon the sense organs, but rather is influenced by the state of the individual as well. Thus a hungry person is more likely to notice food than a well-fed one, and a coin looks larger to a poor child than to a richer one. In somewhat the same way, Kant claims that our experience of the world is not simply given from without, but is the result of a process of organizing our sensations by means of certain concepts. Thus, we think of the world in terms of cause and effect not because there is any direct sensation of causes in the way that there is of colors and shapes, but because causation is one of the ideas which the human mind inevitably uses in the interpretation of experience. Kant holds that causation and the other categories are the same for all people and that the objectivity in our judgments depends upon their use.

In the *Critique of Pure Reason* Kant sets himself the task of discovering a complete list of categories and of showing that they must apply to all experience. In the former inquiry he discovers 12 categories in all, arranged in four groups of three—the categories of quality, quantity, relation, and modality. Of these, the individual categories of cause and substance are most important. The proof that the categories apply to all experience attempted in the "transcendental deduction of the categories" is one of the most difficult arguments to be found in any philosophy.

As a result of this doctrine, Kant distinguishes between things as they are in themselves and things as they appear when organized by the categories. The latter he calls *phenomena* and he argues that scientific knowledge is confined to phenomena.

These two conceptions of category, Aristotle's as the basic types of being and Kant's as basic forms of thought, have been most influential in the history of philosophy. Other views have been intermediate between these. In contemporary philosophy, however, the term is used loosely to refer to any generic concept.

PAUL HENLE,

Professor of Philosophy, University of Michigan.

CATENA, kă-tă'nă, **Vincenzo di Biagio**, Venetian painter: b. Venice, Italy, c.1470; d. there, 1531. He was probably a pupil of Giovanni Bellini, whose style he closely follows in his earlier pictures, as in the *Madonna and Child* (Walker Gallery, Liverpool). In 1505 he worked in Giorgione's studio, and the pictures of his later period are strongly influenced by that famous painter. His masterpiece from that time is the *Martyrdom of St. Christina*, painted in 1520 for the altar of the Church of Santa Maria Mater Domini, Venice.

CATERPILLAR, kăt'ēr-pīl-lēr, the young or larva of a moth or a butterfly that hatches from the egg and when full grown develops into the pupa or chrysalis followed by the adult stage. The head is usually large and bears from two to six simple eyes on each side, and a pair of very small, three-segmented antennae. The segments of the thorax each bear a pair of true legs: these are chitinized, tapering and jointed. They are used not only for crawling but also for holding food in position during feeding. In most caterpillars there are five pairs of pro-legs, false legs or stump legs, situated on the third

to sixth and the 10th abdominal segments: however in some, such as the measuring worms (*Geometridae*), all but the two hind pairs of body legs may be missing. The pro-legs are short and stumpy and terminate in a circle of crochets or hooks which is usually entire, but interrupted in the Microlepidoptera.

There has been no agreement among entomologists as to the correct designation of the proper common names for lepidopterous larvae. In the literature we note caterpillars referred to as appleworm, budworm, cabbage worm, cankerworm, case-bearer, fireworm, fruitworm, hayworm, hornworm, girdlers, leaf rollers, leaf-tiers, looper, meal worm, miner, perforator, podborer, silkworm, skeletonizer, spanworm, tentmaker, webworm, woolly bear and other similar designations. With so many different common names used to designate a particular species, no wonder the layman finds entomological nomenclature confusing. These various designations also give some idea of the characteristics and habits of caterpillars.

Since the Lepidoptera (q.v.) is generally considered to be one of the largest orders of insects, estimated at about 150,000 species, it is reasonable to expect that there are innumerable kinds of caterpillars. These larvae vary in length from 3 millimeters in the small miners, up to 150 millimeters for the largest. In shape they may be elongated, cylindrical, slender, or robust, or they may be flattened or otherwise adapted to fit a particular environment. The colors are usually cryptic so as to match immediate surroundings, but some may be brightly hued and beautifully ornamented with remarkable designs. The surface may be smooth, velvety, shiny or wrinkled and may be clothed in fine, scarcely visible hairs or spines, as is the case with the many cutworms and other caterpillars, or they may be slightly to densely hairy or even spiny like the so-called woolly bears, the tussock and brown tail moths. The larvae of many of the butterflies are rather smooth and naked, but this is by no means true of all species. They may also have various kinds of body tubercles or filaments, and the caterpillars of the swallowtail butterflies of the genus *Papilio* have a pair of delicate tentacle-like or hornlike processes or so-called "scent horns" which are retractile and which when protruded give off a very pungent odor which is believed to be a protection against birds and other enemies.

Caterpillars, which are the growing developing condition of butterflies and moths, are voracious feeders, for they must, in a relatively short time of a few weeks, store up enough food supplies to carry them over through the resting and transformation period known as the pupa or chrysalis stage and the final development into the adult moth or butterfly, which is one of the most remarkable phenomena of the living world.

Caterpillars and the larvae, pupae, and adults of most insects furnish food for many animals, including primitive man. A great many birds are wholly dependent upon this means of subsistence and especially for rearing their young. To destroy the insects would be a fatal blow to these wonderful creatures, and we should be mindful of this fact when appraising the values of insects and especially caterpillars to the economy of man and many other animals.

Much has been written concerning the value

of insects, and especially caterpillars, as food for primitive man. In a recent work 435 separate papers have been listed on this subject, which gives some conception of the importance of insect larvae, in particular, as a source of food.

Modern travelers to Mexico will tell you that one of the delicacies offered to the elite is called "Gusana de maguey," or caterpillars of the maguey, which are prepared by frying them in their own fat.

The most important caterpillar in history is the silkworm (q.v.) which is only now being gradually pushed into oblivion by man-made synthetic silk and substitutes thereof. Silk was first obtained from the cocoons of wild silkworms. The first domesticated caterpillar was the Chinese silkworm, which antedates recorded history, and this insect has been so long in captivity that it can no longer live without the experienced care of man. There are many varieties of this particular species, *Bombyx mori*, and there are also some nine or ten other species of caterpillars that have produced a variety of kinds of commercial silk. Recent wars and the use of synthetic fabrics have greatly reduced the production of silk.

E. O. ESSIG,

Author of "College Entomology."

CATESBY, kâts'bî, Mark, English naturalist: b. probably London, England, c.1679; d. London, Dec. 23, 1749. After studying natural science in London he traveled in North America in 1710-1719 and 1722-1725. He was the author of *Natural History of Carolina, Florida, and the Bahama Islands, with Observations on the Soil, Air, and Water*, 2 vols. (1731, 1743). Others of his books contain the fruits of his studies of bird migration, and of fishes, reptiles, and insects of the Isle of Providence. Catesby influenced the introduction of many American trees and shrubs into English gardens by publishing his *Hortus Britanno-Americanus* (?1737).

CATFISH, a fish of any one of about two thousand species of more than twenty families of fishes of the suborder Siluroidei, order Ostariophysi, representatives of which are found in all warm and temperate seas and in the rivers and streams of all continents. They are extremely varied in size, ranging from creatures an inch long to those of 10 feet and 600 pounds weight. They are extremely varied in specialized structures which enable some to live for long periods out of water; others to live, blind, in caves and in the bottoms of rivers; at least one species protects itself and perhaps secures food by using electric discharges it can produce from a layer of skin. Some can travel overland. Others live in the gills of larger fishes. Some live in waterfalls and others gnaw holes in the sides of larger fishes. From these they draw blood on which to live. A number of them construct nests of one sort or another for the reception of their eggs, burrowing out holes under rocks or simply in the river bottoms; some blow masses of frothy bubbles for their eggs, and some carry the eggs about in their mouths, while still others carry the eggs in a layer attached to their bellies. Some are reported to develop folds of tissue from the lips in which the eggs are carried, and others attach them to a solid surface and apparently forget them.

The body is naked, or covered by bony plates,

and has no true scales. About the mouth are two or more barbels, the longest being at the corners of the mouth. There is usually a stout, generally serrated, spine in front of the dorsal fin, and often another in front of the pectoral fins. These spines are likely to inflict considerable injury if carelessly handled. Some small species, such as the madtoms of North America, have venom glands at the base of the pectoral fin spines. Wounds caused by these can be extremely painful. This is one of the most widely distributed groups of fishes, and is especially abundant in South America and in Africa.

Catfish are sluggish in movement and are mostly bottom feeders, where they eat whatever they find. Some concentrate on algae which they scrape from the stones on which it grows. Because of their size and abundance they form an important food item in the countries in which they are found, but because of their feeding habits their flesh is not considered of high quality. North and Middle America contain about one hundred species, of which a third may be found in the United States and Mexico. The majority are not of much commercial importance but a few have considerable local value. Of these the channel cats of the genus *Ictalurus* are the most sought. They range from the Prairie provinces and the Hudson's Bay region of Canada through most if not all of the Mississippi Valley and southward to Florida and northern Mexico, typically in lakes and larger rivers. The method of capture is usually by "trot lines," which sometimes are a mile long. The catfish move with the seasons, north in spring and summer, south in fall and winter, spreading over swamps and adjacent land at the time of the spring floods. At this time they may be caught on "brush lines." Along the southern Mississippi the blue catfish, *I. furcatus*, is the most important. This averages about twenty pounds but reaches 150 pounds. The range of the white cat of the Potomac, *I. catus*, crosses that of the blue, but this fish is smaller and may be distinguished by the very wide head and the deeply forked tail. Several species have been successfully transplanted into Californian waters. The bullheads, *Ameiurus*, found only in North America, afford considerable sport to anglers, and are edible.

The armored catfishes are peculiar to South America and some of the smaller species, such as the *Corydoras*, and smaller specimens of other families are well known in domestic aquaria. There are also some freshwater catfishes in Australia, the only representatives of the order Ostariophysi found there.

Malapterurus, the electric catfish of the fresh waters of tropical Africa, has been known for many years as a peculiar fish. It was pictured in Egyptian hieroglyphics, and one of its names, translated, means "he who frees many," possibly referring to the fact that a fisherman with one in his net would probably be so shocked by the electricity that he would drop his net and thus release the entire catch. The electricity is produced by chemical means in a layer of tissue between the outer skin and the muscle tissue. It has been recorded as exceeding 400 volts, but most specimens probably do not reach this.

Best known of marine catfishes, or Ariidae, are the gaff-topsail catfish, *Bagre marinus*, found from Panama to Cape Cod, and the sea catfish, *Galeichthys felis*, which runs from Texas to Cape Cod. Usually found near river mouths, they are

more plentiful in the southern parts of their range. They are naked, with long barbels and an adipose fin. Large eggs of the gaff-topsail, as well as young fry, are carried in the male's mouth. Another sea catfish, *Arius*, rather abundant in the West Indies and along the Atlantic coast of South America, is often called the crucifix fish because of the formation of the bones of the inner wall of the skull which resembles a crucifix. The outer skull bones were thought to look like a shield or breastplate, which gave the fish its name, *Arius*, meaning martial. This fish has also been known under the generic name, *Sciadeichthys*.

C. W. COATES.

CATGUT, a tough cord made from the intestines of different quadrupeds, particularly those of sheep, but never from those of the cat. The manufacture is chiefly carried on in Italy and France. The texture from which it is made is that which anatomists call the muscular coat, which is carefully separated from the peritoneal and mucous membranes. After a tedious process of steeping, scouring, fermenting, and inflating, the material is twisted, rubbed with horse-hair cords, fumigated with burning sulphur to improve its color, and dried. Cords of different size, strength, and delicacy are obtained from different domestic animals. The intestine is sometimes cut into uniform strips with an instrument made for the purpose. To prevent offensive effluvia during the process, and to get rid of the oily matter, the French make use of an alkaline liquid called *eau de javelle*. Catgut for stringed instruments, as violins and harps, is made principally in Rome and Naples. For the smallest violin strings three thicknesses are used; for the largest seven; and for the largest bass viol strings 120. It is well known that the membranes of lean animals are tougher than those in a high-fed condition, and there can be no doubt that from the lean and small-sized Italian sheep strings superior to all others are produced. In Naples, whence the best treble strings, commonly called "Roman," are obtained, there are large manufactories of this article. Catgut is also used for surgical sutures and for bowstrings.

CATHA, kăth'ă, a genus of plants belonging to the order Celastraceae, or staff-tree family. The species are mostly natives of Africa, forming small shrubs, sometimes with spiny branches. *Catha edulis* is a native of Arabia, and from the leaves the Arabs make a beverage possessing properties analogous to those of tea or coffee. Under the name of *kât* or *kafta*, the leaves form a considerable article of commerce among the natives. Chewed, they produce wakefulness and hilarity of spirits.

CATHARI, kăth'ă-rî, the name given to themselves by the adherents of numerous heretical sects, undoubtedly of Gnostic and Manichean origin, which swarmed in western Europe, and particularly in northern Italy and southern France, in the 12th century. At that period society had much advanced in wealth and power, which brought their concomitant vices. There were many abuses prevalent in the church, and some of the clergy led scandalous lives. The numerous heretical sects won adherents by violently and indiscriminately denouncing the entire hierarchy, from the pope down to the monastic or-

ders; but their tirades were not more emphatic than the philippics launched against the same scandals by sincere Roman Catholics, their contemporaries, such as Saint Bernard, Saint Hildegarde, Saint Malachi, archbishop of Armagh, and others. But while these sought to procure the eradication of the current abuses by a reformation from within the church, the Cathari (Gr. *katharos*, Lat. *mundus*, *purus*, and *puritanus*, pure, clean) aimed at nothing short of the total destruction of the dominant religion, of its whole system of belief and even of its moral teaching. For not only were the sects styled Cathari (including a host of offshoots of eastern Manichæism), heretics, and reformers, but in their inner circles, dualists, believers in the existence of two supreme principles, the one a good principle, God, and the other an evil principle, the creator of the material world. But open profession was not made of this tenet; it was communicated only to the inner circle in the several Manichean sects, to the elect ones, the *perfecti*, but withheld from the mass of their followers, the *credentes*, the faithful vulgar. To these latter and to outsiders the adepts of the *arcana* of catharism made profession of being strictly reformers of a corrupt ecclesiastical system, and of profound regard for the letter and spirit of the moral law as taught in the apostolic writings. As already said, they enthroned the evil principle as creator of the physical universe; they believed in the divine mission of Jesus Christ, the Son of God, that is, of the good principle; but with the Docetæ they denied that the Son of God had assumed human nature really, and held that his humanity was phantasmal only. In conformity with their tenet of a supreme principle of good and a supreme principle of evil, the initiates condemned as works of the flesh the sacraments of the church as a whole, and looked on the contract of marriage as sinful. They held absolute predestination: that all men belong to one or other of two classes, those who will infallibly be saved, and those who cannot possibly attain holiness: hence their doctrine that an infant dying immediately after birth, if it belongs to the class of those predestined to be lost, is punished as is Judas in hell.

CATHARINE. See CATHERINE.

CATHARTIC, purgative, a medicine used to produce evacuation of the bowels. A laxative is a mild cathartic or purgative tending more to loosen the bowels without the production of watery evacuations. Cathartics may be given by the mouth or by rectum. The effect of cathartic drugs is to stimulate peristalsis of the intestine. This may occur by an increase in bulk of the contents of the intestinal tract through the ingestion of substances containing a large proportion of indigestible matter such as bran or coarse vegetables; by ingesting substances which absorb water and swell, such as agar, psyllium seed, etc. (demulcents); or by drinking salines, that is, magnesium sulphate, which draw fluid into the intestinal tract by osmosis. Certain cathartics act by direct irritation of the intestinal mucous membrane, an example being calomel. A simple and well recognized classification of cathartics on a basis of their action contains 3 general groups. The first includes the laxatives which are mild and act rather slowly with production of a movement within 24 hours. The

second includes the purgatives which are either vegetable cathartics or salines which produce a copious movement in from 1 to 12 hours. The third group is made up of the drastic purgatives of vegetable origin which exert a powerful irritant effect in a short time and are in fact seldom used.

Laxatives.—Classed with laxatives are certain diets containing a large amount of fruit, vegetables, whole wheat, bran, etc. Other laxatives are agar, mixed generally with cooked cereal. Most of the agar is excreted in a large movement within 24 hours. *Plantago seed* (*psyllium seed*) contains a mucilaginous principle producing bulky stools. Liquid petrolatum or mineral oil forms a waterproof coating in the intestine and increases the bulk of the fecal mass by slowing absorption of water. It has the objection of interfering with vitamin absorption.

Simple Purgatives.—These compose most of the cathartic drugs. Among the most widely used is *cascara sagrada*, the dried bark of a shrub containing anthraquinone derivatives. It is intensely bitter unless taken as the aromatic extract and its effect is almost entirely on the colon. It acts within 12 hours, producing a slight griping and is extremely effective. *Cascara* can be repeated and is possibly the best laxative since it is not particularly habit-forming and can be discontinued after regular bowel habits are established. Other laxatives contain *aloe* and *belladonna* in pill form. *Aloe* is likely to cause severe griping. *Senna* is more irritant than *cascara* but is in wide use. *Rhubarb* is efficient in about 8 hours but may have the after-effect of constipation. *Phenolphthalein* is a white powder of synthetic origin acting in 8 to 12 hours. It is efficient even after repeated use but irritates the colon and causes skin rashes. *Castor oil* is of value in emptying the bowel rapidly if the intestine contains toxic matter. *Calomel* (mild mercurous mercury) is a powerful irritant cathartic acting slowly with griping. The saline purges are milk of *magnesia*, *magnesium carbonate*, *magnesium sulphate* (Epsom salts), *sodium phosphate*, and *Seidlitz powders*. Drastic purgatives—these form a small group such as *Jalap* and *Podophyllin*. They are extremely irritant, acting on the small intestine, and are not often used. See also CONSTIPATION.

HAROLD WELLINGTON JONES, M.D.

CATHARTIDAE, ká-thār'tí-dē, in zoology, the American vultures, a family of birds of the order accipitres or Raptores, differing from the more eagle-like Old World vultures (*Vulturidae*) in having the beak comparatively slender, straight, and blunt, the complete absence of a septum between the nostrils, the much more largely naked head and neck, and the weak feet with elevated hallux and but slightly curved claws. Altogether they are less predaceous birds, which feed exclusively on carrion or attack weakling animals. Five genera, each with but one or a few species, are found in America, more especially in the warmer parts. Among them are the carrion crow, the condor, and the turkey buzzard (qq.v.).

CATHAY, ká-thā', name used in the Middle Ages by Marco Polo and others to designate China. It is derived from the Persian *Khitai*, a

kingdom in north China established in the 10th century by the Khitans, a Tatar race. In modern Russian, the name for China is *Kitai*.

CATHCART, Sir George, British army officer: b. London, May 12, 1794; d. Crimean Peninsula, Russia, Nov. 5, 1854. The 3d son of William Schaw, 1st Earl Cathcart (q.v.), he joined the army in 1810, and during 1812-1814 he served as his father's attaché in Russia. From 1815 to 1818 he was aide-de-camp to the Duke of Wellington; and in 1838 he went to Canada in command of the King's Dragoon Guards. Appointed governor and commander in chief at the Cape of Good Hope in 1852, he subdued the rebellious Kaffirs and Basutos. With outbreak of the Crimean War (q.v.) he was given command of a division. He was killed at the Battle of Inkerman. His *Commentaries on the War in Russia and Germany in 1812 and 1813* was published in London in 1850.

CATHCART, Sir William Schaw (1st EARL CATHCART), British army officer and diplomat: b. Petersham, Sept. 17, 1755; d. Glasgow, Scotland, June 16, 1843. He was the son of Charles Cathcart, 9th Baron Cathcart (b. 1721), and succeeded him in 1776. Entering the army, from 1777 to 1780 he served in North America in command of the "British Legion," an irregular corps, and during 1793-1795 he took part in the campaigns against the French in the Low Countries. In 1801 he reached the rank of lieutenant general, and from 1803 to 1805 he was commander in chief in Ireland. He led the expedition to Hannover in 1805, and in 1807, after commanding the land forces in the attack on Copenhagen, he was created a viscount for his services. In 1812, with the rank of general, he was sent to Russia as ambassador and military commissioner. He accompanied Emperor Alexander I in the campaigns against Napoleon, and in 1814 he received an earldom. Until 1821 he continued as ambassador at St. Petersburg.

CATHEDRAL. See CATHEDRALS AND CHURCHES.

CATHEDRAL, The, a novel by Hugh Walpole, published in 1922.

The central figure of the story is Adam Brandon, archdeacon of the great English cathedral of Polchester, and the theme is the archdeacon's fateful decline from the heights of dignity, authority, and esteem to the depths of isolation, humiliation, and bitterness. His greatest enemy is himself, in that he suffers, much as did Greek tragic heroes, from the deadly blindness of pride. Through a series of misadventures, most of which could have been minimized or even avoided altogether by a more humble and perceptive man, Brandon loses his only son to a girl of whom he cannot approve; his wife to another man; his influence to a clerical rival; and ultimately both his mental balance and physical health to the gradual inroads of corrosive rage and frustration. His death from a sudden attack of apoplexy takes place at a routine meeting of the cathedral chapter just after he has suffered his final, cumulatively symbolic defeat at the hands of his rival.

Important characters of the novel, apart from Brandon, are his lonely, colorless wife, Amy; his rebellious son and loyal daughter; and his shrewd, deceptively benign, clerical adversary, Canon Ronder. Always in the background, Polchester

Cathedral broods like a sacerdotal sphinx over the cathedral town and its inhabitants.

Considered Walpole's most important work, *The Cathedral* tells a highly dramatic and impassioned tale of minds both noble and mean, of emotions both lofty and base, in prose which now and again rises to poetic power.

CATHEDRAL, The, a poem by James Russell Lowell, published in Boston in 1869. The particular cathedral which suggested the thought of the poem is that of Chartres.

CATHEDRAL OF SAINT JOHN THE DIVINE. See CATHEDRALS AND CHURCHES.

CATHEDRAL PEAK. (1) A mountain of the Sierra Nevada range, 10,933 feet in height, situated in the northeastern part of Mariposa County, Calif. It is in Yosemite National Park, and contains the source of the Merced River. (2) A mountain in Pitkin County, Colo., in the west central part of the state, 14,100 feet high. (3) A mountain in Yellowstone National Park, northwest Wyoming, having a height of 10,600 feet.

CATHEDRAL SCHOOLS. See ALMONRY SCHOOLS.

CATHEDRALS AND CHURCHES. A cathedral (from Greek *καθέδρα*, "seat") is the administrative church of an ecclesiastical diocese presided over by a bishop and usually located in a town or city. It customarily includes the *cathedra*, or chair, of the bishop. Since the Reformation the word has sometimes been used by nonepiscopal faiths to designate churches of exceptional size or importance. Differentiated from cathedrals are monastic and parish churches, which will be discussed later.

The great period of cathedral building in Western Europe was the late 12th and the 13th century, when episcopal centers tended to shift from the rural monasteries to towns, many of these newly founded. Between 1170 and 1270 approximately 80 cathedrals were constructed in France alone. In form these Gothic cathedrals evolved from the wood-roofed Early Christian basilicas in response to physical, liturgical, and administrative requirements, and some knowledge of the requirements is necessary to an understanding of this cathedral form.

The liturgical activities within a Gothic cathedral were similar to those of the earlier monastic cathedral, although its canons or priests were not bound by such specific rules of common life. These activities centered in the almost continuous celebration of divine worship with its varied round of services, processions, and festivals. *Matins* began the canonical hours and were observed as early as midnight in some cathedrals—at sunrise in others. *Lauds* followed, after which the Mass of the Virgin was celebrated. The bell announcing *prime*, or the first of the canonical hours, was rung soon after. *Tierce* was said about 9 o'clock, with *High Mass* at 10 followed by *sext* and *nones*. Evensong might be said about 3 in the afternoon, with *vespers* and then *compline* at 7 or 8 P.M.

The most important daily service was that of High Mass, but many special services, such as those of Christmas, Easter, and Pentecost, and those on anniversaries of particular saints, in-

volved special features. Most services culminated at the high altar and were conducted primarily in the presence of the clergy. Elaborate processions played an important part in the services and these necessitated easy entrance and exit to several sections of the cathedral and easy circulation about it. Provision had to be made for the display of relics either to those assembled in the nave or to pilgrims visiting the several chapels. The circulation of pilgrims from chapel to chapel and to the crypt beneath posed a formidable architectural problem. The safeguarding of the relics and of the cathedral treasure was also of high importance, as was the need for the instruction of the faithful by visual as well as auditory means. Above all, however, was the need for fire resistance, since the cathedral was often situated in the midst of closely packed combustible houses and there was no adequate fire-fighting equipment. Added to these requirements were others relative to various needs and activities of the residentiary canons and vicars, a meeting place for the conduct of ecclesiastical business, space for the accommodation of penitents and alms seekers, a school, and a library. With this sample view of life within a medieval cathedral, we are better prepared to examine its architectural form and setting.

The physical location of a cathedral was usually impressive. One might cite the massive bulk of Durham rising from a granite ledge above the valley of the Wear or the upspringing silhouette of Chartres surmounting a geometric melange of rooftops.

In general form the cathedral of western Europe followed the long rectangular shape of the Early Christian basilican church, was entered from the west, and reached its climax in the high altar at the east. Its central space or nave might be flanked by single or double aisles. In France, Flanders, Germany, and Spain these continued in a semicircular ambulatory about the high altar. In England, the aisles formed a rectangular eastern termination. An example of this simple type may be seen in the cathedral at Bourges, its impressive length visually emphasized by the lack of any cross arms.

Most cathedrals incorporated in the general rectangular shape described above a cross arm or transept—slightly emphasized, as at Notre Dame in Paris, or vigorously expressed, as at Ely in England. Such a single transept formed a Latin cross in plan. Where two such transepts were employed, as was common in England, their double arms formed a patriarchal cross.

Towers served as high platforms for the ringing of bells and when capped with spires, as was usually intended, they served as vertical symbols of the faith—harmonious aesthetic elements of a dynamic whole. Simplest in tower arrangement was the cathedral with but a single western tower placed over the entrance, as at Ulm, Germany, or over the crossing of nave and transept, as at Norwich, England. Notre Dame, Paris, illustrates the more usual French arrangement, with two western towers and a slender spire or *flèche* over the crossing. Laon in France was planned for seven towers, two flanking the western façade, and each transept façade, and a *flèche* over the crossing. Chartres was planned for nine towers. The dramatic role played by the crossing towers in admitting a flood of top light is strikingly illustrated in some English cathedrals, where large central towers were especially featured.

The continental cathedrals usually fronted on an open square. It was there that the drama of the miracle plays was partly or wholly enacted. It was there that goods were often sold in open stalls on market days. It was there that the narrow but principal streets of the town often debouched. Small wonder that the town felt itself a vital part of the visible church: the people lived in its presence, contributed to its fabric, and participated in its liturgical drama. For their instruction, the portals and façade were adorned with saints and sinners, enhanced by gilt and color. Feudal lord and market woman were alike reminded of the horrors of hell by the Last Judgment over the central door. The Wise and Foolish Virgins warned them of the penalty of unpreparedness. At Notre Dame, Paris, the lamb giving its own wool bespoke the Virtue of Charity. And although the western façades of the English cathedrals played a less important role than those of France, their didactic imagery was similar and abundant.

Entrance to the cathedral for the people was usually through a narthex or vestibule. The canons customarily entered from the cloister, if there was one.

The interior space, suffused by jewel-like color from multitudinous windows, was divided into three major parts: nave, choir, and sanctuary. Supplementary to these were the retrochoir, the ambulatory, and the chapels containing subordinate altars and shrines.

The nave on the west or entrance side was for the laity, although sometimes regarded by the canons as a prelude to the choir and the more sacred area beyond. It frequently had its own altar, located on the west side of the choir screen and used primarily for the lay congregation, though also used for some of the minor services of the canons. The baptismal font was found at the opposite end, near the entrance. Sermons received diverse emphasis in the medieval cathedral and varied in length from brief meditations to lengthy exhortations. Sermons to the clergy were ordinarily delivered in Latin from a lectern within the choir. Those to the people were delivered in the common tongue from a pulpit located west of the choir screen. Worshipers in the medieval cathedral stood or knelt and benches for the laity only appear in western Europe from the 14th century.

The choir space containing the stalls of the clergy might begin at a point several bays west of the crossing—a common practice in Spanish cathedrals—or at the eastern side of the crossing. It was usually at a higher level than the nave. The choir stalls, whether or not accompanied by a choir screen, served to separate this space from the side aisles. These stalls were often assigned according to the rank of the canons. In many cathedrals, the dean was the immediate head under the bishop, served as the executive authority of the cathedral, and occupied the first stall to the south of the choir. In some cathedrals, the provost or archdeacon occupied this position. The opposite stall was assigned to the precentor, who had charge of the singing. If the bishop was present he might occupy his throne, the dean's stall or, in some instances, a special stall. The high altar, the most sacred element of the cathedral, usually stood at the east end of the sanctuary and was elevated by one or two steps. This altar alone was required to stand free so that it might be asperged from all sides and

was planned with ample space before it for the celebrants and his assistants. It was often flanked by richly embroidered riddel curtains to protect the flickering candles and was sometimes dramatically backed by a decorative screen or reredos.

The development of the space around and behind the altar provided for the easy circulation of canonical processions and pilgrim visitors and for chapels and shrines containing the relics of saints, kings, and bishops. At Canterbury, England, it was the shrine of Thomas a Becket which attracted thousands of pilgrims and a kingly treasure of gold and jewels. At Le Mans, France, the circling ambulatory was studded with thirteen radiating chapels. At Reims the generous ambulatory space facilitated the coronation ceremonies traditionally held there.

Structurally the Gothic cathedral was based on the principle of arch and vault, a dynamic mode of construction, as the arch and the vault are constantly tending to thrust themselves apart. Only the opposition of the powerful external stone buttresses maintained the necessary balance. Such a stone covering as was provided by rib and vault made the cathedral relatively secure against fire, although the lead-covered timber roof above the vault remained vulnerable. This was demonstrated by the fire at Reims in 1481, in which the lead of the roof melted and ran through the gargoyles to the ground and the roof timbers were consumed, but the 20-inch thick stone vault remained intact. The demonstration was repeated during World War I, when the bombardment of Reims was followed by fire. Again the lead covering was melted and the timber trusses burned, but the stone vault survived.

Separate from the cathedral but closely related to it were the canonical residences, the chapter house, the library, and other necessary buildings. It is regrettable that so few of these auxiliary structures still stand, for such ensembles gave the cathedrals their maximum exterior effects.

Cathedrals in eastern Europe developed in contrast with those of the west. The Byzantine empire centered in the teeming city of Constantinople, and Constantinople is located at the mouth of the Black Sea, where east and west do meet. In the eastern church the bishop was known as the patriarch or metropolitan. The requirements of his ecclesiastical seat were similar to those of his western counterpart—calling for narthex, central space or nave, choir, and sanctuary, usually arranged in ascending levels. However, the form of the eastern cathedral was symmetrical about a central point rather than along a central line as in the west; the eastern cathedral was a circular, octagonal, or square building rather than a rectangular one. Separation of the sexes was customary in the eastern church, with women frequently assigned to the gallery, which was in consequence called the gynaeceum. The altar of the eastern cathedral was more completely separated from the choir than the altar of the Gothic cathedral. This more complete separation was accomplished by an iconostasis, or image-bearing screen, which was pierced by three doorways.

The supreme achievement of the Byzantine builders was the cathedral of Hagia Sophia, or Divine Wisdom, in Constantinople. In plan, this cathedral combined a suggestion of western rectangularity with eastern centrality. It was

erected between 532 and 537 by two architects from Asia Minor, Anthemius of Tralles and Isidorus of Miletus, and featured a great central brick dome (107 feet in diameter) shouldered by half domes on the east and west. Massive buttresses rose above the aisles and galleries on north and south to absorb the outward thrust of these domes. The entrance was from the west through an open court, an outer and inner narthex. Within, the light from the 40 windows at the base of the central dome, augmented by that from 174 others, reflected the myriad colors and golden glow of the mosaic which sheathed the walls and vaults.

The type of the later Byzantine cathedral and church was established by the Nea Ekklesia, or new palace church, in Constantinople. This church had five domes rising from a square plan, the highest above the center at the crossing of two

vision for them and stimulated the study of mathematical relations in space. Harmonic proportions drawn from musical analogies, symmetry, and the precise use of classic columns, pediments, and ornament gave the Renaissance cathedrals a temple-like appearance. On their interiors the same elements governed and Roman vault types replaced the ribbed vaults of the Gothic era. Major worship and administrative requirements differed but little from those of the medieval period, although the work of the preaching friars and of such fervent spirits as Savonarola had increased the importance of the sermon. In music, Gregorian plain song had been developed into part singing and then into harmonic compositions. And although the Post-Reformation saw the building of numerous Protestant churches and some changes in worship, the Renaissance cathedral form persisted even in Protestant churches.

barrel vaults. Four lower domes surmounted the four corners. Although nothing remains of the Nea itself, its general form is reflected in hundreds of cathedrals and churches in Russia and Greece and throughout the Balkans. Among these one of the most beautiful is the 12th century Cathedral of the Assumption at Vladimir, Russia. This cathedral was built of white sandstone and capped by five helmet-shaped domes. It has long been regarded as the crowning achievement of the Russian builders and was taken as the model for later cathedrals.

The Renaissance cathedrals of western Europe illustrate the change of ideal wrought by the classical studies of the Humanist scholars. To the Renaissance architects Gothic cathedrals seemed barbaric. They had been won over by the classic geometry of antiquity. The discovery of the laws of perspective opened a new world of

St. Peter's, Rome, is the outstanding representative of the period. In the 120 years of its building, successive architects alternated between central and basilican plans. The final form, that of a Latin cross, was achieved by the architect Carlo Maderna. Both nave and transepts of St. Peter's are covered by semicircular barrel vaults, 150 feet high, and above their intersection rises Michelangelo's vast dome, 138 feet in diameter. This dome is visually supported on the exterior by a drum of coupled columns. However, its real stability depends, as does the stability of most Renaissance domes, on girdling chains embedded in the walls. Such concealed construction differs markedly in external expression from the construction of the Gothic cathedrals, in which the visible buttresses act in contrapuntal rhythm to oppose the concentrated thrusts of the internal vaulting. Very different also are the classical

columns, mouldings, and pediments in comparison with the slender colonnettes, pinnacles, and pointed arches of the Gothic builders. With the Renaissance a new architectural world had dawned and its form was determined by new ideals rather than by new requirements.

England at the beginning of the 18th century saw Christopher Wren's masterpiece, St. Paul's Cathedral, nearing completion in London. In St. Paul's, as in St. Peter's, Rome, the dome at the crossing is the dominant element, but that of St. Paul's seems more serene in its studied simplicity. Two towers flank the two-story façade, while within, a series of saucer-domed bays leads to the 112-foot dome at the crossing.

In Europe few complete cathedrals were built in the rich Baroque style which flourished during the 17th century probably because the diocesan centers were already established. However, in South America and Mexico a number of cathedrals did come under this Baroque influence, often in combination with Gothic vaults or classic interiors. Such is Cuzco (Peru) Cathedral, begun in 1560 but only completed in 1653. It is rectangular, with three Gothic vaulted naves of equal height carried on immense classic piers. The façade has a full Baroque portal set against the bare reddish-brown stone.

In the 19th century two revival styles, Gothic and Classic, vied for supremacy. In 1789, the same year in which George Washington took his oath of office as president of the new American republic, the numerous Catholic parishes in the United States were constituted into a diocese and Baltimore became the episcopal see. A new cathedral was imperative and Benjamin Henry Latrobe, a London-trained architect, was commissioned to prepare designs. He presented two, one Gothic and one Classic. The latter was accepted and finally erected, although Latrobe made many modifications during the period of construction (1806-1821). Built of granite on a cruciform plan, Baltimore Cathedral was probably the first domical church of any kind in the eastern part of the United States. The present onion domes capping the towers, the Greek Ionic portico, and the eastward extensions were all built later.

Russia in the 19th century took pride in the erection of the classic Cathedral of St. Isaac in St. Petersburg (Leningrad). This was designed and built by the French architect Richard de Montferriand. Magnificently placed in the great square which extends some 1,800 feet from the river, it presents a huge rectangular mass surmounted by a dome and four corner cupolas. Porticoes extending from the four faces modify the central block into a cruciform shape. The columns of each portico are of rose granite and, with their bronze capitals, attain a height of 56 feet. Because of the marshy nature of the site, the dome was constructed of cast and wrought iron, an example of lightened construction undoubtedly known to the American architect, Thomas Ustick Walter, when he designed the iron dome of the national capitol in Washington, D.C., in the face of similar soil conditions.

Most 19th century cathedrals in the United States were Gothic or Gothic Revival, as the style is commonly called. St. Patrick's Cathedral (1858-1879) in New York is a famous example. It was designed by James Renwick, probably with Cologne Cathedral in the back of his mind, and was the first major Gothic Revival cathedral

to be built in the country. Granite is the major material. However, the vault is of wood and plaster, eliminating the necessity for flying buttresses, although external pinnacles suggestive of buttresses are employed.

A second example in New York City rises from Morningside Heights. This is the Cathedral of St. John the Divine, originally designed in an eclectic medieval style by George Lewis Heins and Christopher Grant LaFarge in 1888 but transformed into French Gothic by Ralph Adams Cram in the years following 1911. It is comparable to the largest European cathedrals in size, surpassed only by St. Peter's and the cathedral at Seville. Its vault is poised 124 feet above the floor and its nave has the immense span of 100 feet. The total length is 601 feet.

In Washington, D.C., the Episcopal Cathedral of St. Peter and St. Paul by Henry Vaughan and George F. Bodley is similar in general form, although more English in its vaulted interior. It occupies a splendid site above the Potomac and it will have a total length of 504 feet when completed. Since the death of the original architects the work has been carried on by Frohman, Robb, and Little.

Christ's Cathedral, Liverpool, designed by Sir Giles Gilbert Scott, was begun in 1904. Also magnificently located, on an abandoned quarry high above the city, its red sandstone bulk is clearly visible to ships approaching the harbor. The cathedral is cruciform with double transepts. Although Gothic in inspiration, it is not copyistic and incorporates massive walls and piers in place of the customary Gothic lightness. The interior vaults, 116 feet high, rise to 176 feet in the central space under the tower. Heating is of the radiant type, with warm air circulated in under-floor concrete flues—the first large-scale installation of this type of heating in England.

Churches.—Churches may be broadly classified under two main headings, monastic (including collegiate and friars' churches) and parish. Both categories might be further subdivided according to allegiance, geography, chronology, and other differentiations. However, geographical and chronological variations resembled those of the cathedrals, and cathedrals by reason of their importance were usually the major influences in the architectural expression of any given time and place.

The great period of monastic church building was the 11th and 12th centuries, the pre-Gothic period commonly called Romanesque. It was in the late 11th century that the third abbey church at Cluny was begun and the influence of this church spread far and wide among the 2,000 dependencies of the Cluniacs. The church was a big one, 615 feet long, with massive walls seven and one-half feet thick. It stood to the north of the cloister around which the life of the Cluniac brothers revolved. Its plan was that of a double-armed or patriarchal cross, with double aisles on either side of the central space. It bristled with nine towers. Its eastern termination included the semicircular ambulatory with radiating chapels for Cluny, and its dependent churches were pilgrimage churches with many relics and many altars. Nine major services were celebrated during each 24-hour period and, as in the cathedrals, processions played an important part. The interior of Cluny was vaulted by a 100-foot catenary barrel vault reinforced by transverse arches and lighted by round-arched windows. Space was divided into nave,

choir, and sanctuary in an ascending order of importance, though the nave was seldom used. The Cluniacs delighted in carving, color, and windows of jewel-like glass.

The Cistercians, on the other hand, were anti-decorative. Their churches, although contemporary with those of Cluny, bespeak their extreme asceticism. Their abbey at Fontenay has no towers. Its interior, covered by a pointed barrel vault, is relatively low and bare. Its eastern termination is rectangular. The conventional buildings around the cloister share this atmosphere of severity. Nevertheless, the relationship of building to building, the relationship of landscape elements, and the absence of decorative detail usually resulted in an effect of peaceful and beautiful simplicity. Years diminished the Cistercian architectural asceticism, however, and after 1200 ornamental features were used with

Both attached great importance to preaching. The consequences of these beliefs are to be seen in their churches. Usually located in the poorer, more crowded districts of the cities, they sought to provide maximum clear space at minimum cost.

The Franciscan Church of Santa Croce (1294-1442) in Florence, by Arnolfo di Cambio, is an example. Its interior volume is about double that of the Cathedral of Notre Dame, Paris, but its vast nave is covered by timber trusses instead of vaults and its exterior is of brick instead of stone. Even Franciscan austerity did not endure, however, and with the accumulation of wealth, elaboration of their churches inevitably followed.

For the Dominicans a church with a double nave divided by a row of columns, a "hall church," became the accepted type. It is illustrated by the Dominican church in Toulouse, France.

Fountains Abbey, near Ripon, England. A Cistercian abbey, begun in 1132, now in ruins. This artist's reconstruction shows relation of abbey church to monastic buildings. greater freedom. A classic example of this relaxation of austerity in Cistercian architecture is the Abbot Huby tower which was added to Fountains Abbey, Yorkshire, in 1494-1526. A specimen of late and rather coarse Perpendicular, it contrasts strikingly with the austere 12th century nave. Though the order was never as large as the order of Cluny, the Cistercians' abbeys numbered 1,800 by 1260, and it was the Cistercians who carried the new Gothic style to Italy.

Succeeding the Benedictines and Cistercians and, in one sense, the bishops and canons of the cathedrals, were the friars of the late 13th and the 14th centuries. Of the orders of friars the Franciscans and Dominicans were chief. Both believed themselves called to work among the masses. Both began in austerity, with the Franciscans placing special emphasis on poverty.

The change in ideals introduced by the Renaissance, of course, affected monastic churches as well as cathedrals. A key example in the so-called Mannerist style (i.e., post-Renaissance style of the 16th century) appears in Il Gesù, Rome. It was built for the Society of Jesus, an order especially identified with the Counter Reformation. Begun in 1568, this church combined the medieval longitudinal scheme with the central scheme of the early Renaissance—by no means a new conception. The two-story façade of Il Gesù had likewise been anticipated a century or more before. What was new was the dramatic handling of light in the interior space, the purposive contraction and darkening of the vaulted bay preceding the crossing space in order that the light pouring down from the dome above would bring a sense of fulfillment. Another feature was the development of the two transept altars, one dedi-

cated to St. Ignatius of Loyola, the founder of the order, the other to St. Francis Xavier. Above the lower arcade of the nave, balustrades and grilles were incorporated. These permitted the novices to hear the sermons and participate in the services without being seen, an arrangement which became characteristic of Jesuit churches.

In the 18th century Baroque monasteries of South Germany and Austria, the abbey churches were brought to a dazzling crescendo of undulating walls, complex interior spaces, and sparkling decorative compositions carried out in pink, gold, and white and employing a full orchestration of all the arts. In such monastery churches as Weingarten (1723), near Lake Constance, and Melk (1702), overlooking the Danube, one is invariably charmed by the delicacy, the vivacious movement, and the illusory effects attained.

Parish churches, though less important in establishing architectural trends, are omnipresent in the western world. Almost every medieval village and hamlet had its parish church. York, England, with a population of 11,000 in the 14th century had 45 parish churches. Thousands of medieval parish churches still remain to us and to these have been added tens of thousands in other styles.

The function of the parish church was to serve the religious needs of the people of the parish, the district within reasonable distance of the church. In doing this the church usually served a broad social purpose as well and won a large place in the affections of the people. Within the pre-Reformation English parish church mystery plays were performed, property deeds were stored and, at certain festivals, dancing was allowed in the nave. Fairs were held in the parish churchyard and contracts were often signed under its entrance porch.

Parish churches range through every conceivable type and style. Some are like rustic huts; others are as large as cathedrals. Some were built in one great campaign, while others literally grew bay by bay as needs developed. Some have aisles, some do not.

Representing the survival of the Gothic tradition is St. Thomas's Church in New York City, designed by Bertram Grosvenor Goodhue in 1906 and splendidly comparable with its medieval prototypes.

In complete contrast, yet beautifully expressive of simplicity and studied relationships, is the Chapel of the Transfiguration at Moose, Wyoming, designed by the Reverend R. H. Balcom. In this the breath-taking view of the Tetons becomes the reredos against which the altar is placed.

In the struggle toward the more economical and efficient spanning of space with the relatively new material of reinforced concrete two examples seem especially worthy of citation. One is the church of St. Jean l'Évangéliste, Paris, designed by Anatole de Baudot in 1894, when the theory of reinforced concrete was just being formulated. The other is Auguste Perret's Notre Dame du Raincy (Paris), designed in 1922. Both are pioneer expressions of the material and, as such, experimental.

Many other new notes have been sounded in the design of churches to meet contemporary needs with contemporary materials and technology: the Church of Christ in Columbus, Indiana, by Eliel Saarinen; St. Ann's, Normandy, Mis-

souri, in which the architect, Joseph D. Murphy, received whole-hearted collaboration from the stained glass craftsman-designers, Frei and Harmon; the small and highly adaptable Methodist church which Schweikher and Elting built in Plainfield, Iowa; the highly imaginative Unitarian church in Madison, Wisconsin, by Frank Lloyd Wright; and the churches of Pietro Beluschi in Portland, Oregon. These and scores of others attest that the 20th century is making its contribution to the house of God and is significantly symbolizing the creative spirit of man's devotion.

versity of Illinois.*

CATHELINEAU, kât-lê-nô', Jacques, French Vendean general: b. Pin-en-Mauges, Maine-et-Loire, Jan. 5, 1759; d. St.-Florent-le-Vieil, July 4, 1793. In March 1793 he helped assemble a band of local recruits for an insurrection against the Republicans and led them thereafter. The storming of Cholet was the greatest of his military exploits. He combined with other Vendean leaders in the taking of several more towns and became the commander in chief of the whole force after the taking of Saumur in June. In the decisive attack on Nantes Cathelineau was mortally wounded and the army was repulsed. He was often referred to as the Saint of Anjou.

CATHER, kăth'ēr, Willa Sibert, American author: b. Winchester, Va., Dec. 7, 1876; d. New York, N. Y., April 24, 1947. When she was still a child, her family moved from Virginia to Nebraska, where she lived until she completed college. She attended high school in Red Cloud and was graduated from the University of Nebraska in 1895. Her love for music and literature helped her decide to leave the country and live in a city. She went to Pittsburgh, Pa., and worked on the staff of a newspaper, later teaching English at Allegheny High School. It was at this time that her first writing was published: a volume of poetry, *April Twilights*, in 1903 and a collection of short stories, *The Troll Garden*, in 1905. From 1906 until 1912 she was an editor of *McClure's Magazine* in New York City, becoming managing editor in 1908. After the publication of her first novel, *Alexander's Bridge*, in 1912, she devoted all her time to creative writing. She traveled widely in Europe and the United States and once tried to make France her permanent residence. Her love for the prairies brought her back to America. Miss Cather was often considered one of three or four outstanding novelists whom the United States produced in the first half of the 20th century. She was given honorary degrees from Columbia, Princeton, Michigan, Nebraska, California, and Yale universities. The last years of her life were spent in New York City; she was buried at Jaffrey, N. H.

The beauty of style in her writing as well as

the selection of narrative material made her work widely appreciated and admired. Her earliest success came from stories of the Nebraska plains: *O Pioneers!* (1913), *The Song of the Lark* (1915), and *My Antonia* (1918). She was interested in immigrant families who were living in Nebraska at the close of the 19th century and especially admired the pioneering spirit. In the majority of novels she wrote of the sensitive person or artist who finds himself unable to compete in a mercenary world. She also used this theme in such successful short stories as *A Wagner Matinee* and *The Sculptor's Funeral* which are in the collection *Youth and the Bright Medusa* (1920). Her great love for music is evident in the choice of characters as well as in the writing.

A Lost Lady (1923) is frequently judged her finest novel. In a study of the decline of a woman of refinement Miss Cather pictured the changing social pattern and the commercializing of America's Middle West in the early days of the 20th century. Two of her most popular novels are *Death Comes for the Archbishop* (1927) and a story of Quebec, *Shadows on the Rock* (1931). *One of Ours* (1922) was awarded a Pulitzer Prize for fiction. In *Sapphira and the Slave Girl* (1940) for the first time she used her birthplace, a farm in Virginia, as a setting, but the novel was not considered one of her major achievements. Her other published work includes: *The Professor's House* (novel, 1925); *My Mortal Enemy* (novel, 1926); *Obscure Destinies* (short stories, 1932); *Lucy Gayheart* (novel, 1935); *Not Under Forty* (essays, 1936); and *The Old Beauty, and Others* (short stories, published posthumously, 1948).

CATHERINE, Order of Saint, the name of two organizations of very different character: (1) The Knights of Saint Catherine on Mount Sinai, a medieval military order, instituted for the protection of the pilgrims who came to visit the tomb of Saint Catherine of Alexandria on this mountain. (2) A former organization in Russia, constituting a distinction for ladies, and instituted by Catherine, wife of Peter the Great, in memory of his signal escape from the Turks in 1711.

CATHERINE, Saint. (1) **SAINT CATHERINE OF ALEXANDRIA**, Christian virgin and martyr: b. Alexandria, Egypt; d. about 307. According to legend, she publicly confessed the Gospel at a sacrificial feast appointed by Galerius Valerius Maximinus, at that period governor of Egypt, and was put to death by beheading after a vain attempt to torture her on a spiked wheel. Hence the name of Catherine wheel (q.v.). Her body was conveyed by angels to Mount Sinai, where the monastery of Saint Catherine was built. No less than 50 heathen philosophers who were sent to convert her in prison were themselves converted by her winning eloquence, whence she is the patroness of philosophers and learned schools. Having steadily rejected all offers of earthly marriage, she was taken in vision to heaven, where Christ plighted his troth to her with a ring. This subject has been a favorite one with many artists (as signifying the union of the redeemed soul with Christ), the Christ being usually represented as an infant. It has been suggested that the attributes of the unhistorical Saint Catherine seem to have been derived from those of the ac-

tual Hypatia, a heathen who suffered death at the hands of Christian fanatics. Her festival falls on November 25. (2) **SAINT CATHERINE OF SIENA**, one of the most famous religious of Italy: b. Siena, Italy, March 25, 1347; d. Rome, April 29, 1380. At the age of 16 she took the habit of a Dominican Tertiary, that is, the third order, living under the rule of Saint Dominic while remaining at home. Therefore, afterward she was a patron saint of the Dominicans. Gifted with extraordinary spiritual insight, she felt conscious of a divine message to take part in public affairs. Acting on this belief, she corresponded with the principal rulers of Italy, and in 1377 she was able to prevail upon Pope Gregory XI, for the sake of the church, to leave Avignon and return to Rome. In 1378 Pope Urban VI summoned her to Rome, where she labored until her death. Her last public work was the reconciliation of the papacy with the Roman people. She was given, it was said, extraordinary tokens of favor by Christ, whose stigmata were imprinted upon her body. She wrote devotional pieces, letters, and poems. In 1461 she was canonized. Her festival falls on April 30. (3) **SAINT CATHERINE OF BOLOGNA**, abbess of the Order of Poor Clares: b. Bologna, Italy, 1413; d. there, 1463. She founded the Poor Clares' Convent of the Holy Sacrament at Bologna. Pope Benedict XIII canonized her. Her festival is on March 9. (4) **SAINT CATHERINE OF SWEDEN**, Swedish religious: b. about 1330; d. March 24, 1381. She was the daughter of St. Bridget (q.v.) and Ulf Gudmarsson. In 1373 she succeeded her mother as abbess of the convent of the Order of the Brigidines at Vadstena. Her festival is commemorated on March 22. (5) **SAINT CATHERINE OF GENOA**, an Italian mystic: b. Genoa, Italy, 1447; d. there, Sept. 14, 1510. A member of the noble family of Fieschi, she devoted her life to work among the sick and poor, notably during the plague epidemics at Genoa in 1497 and 1501. She was canonized in 1737. Her festival is on July 22. (6) **SAINT CATHERINE OF RICCI**, an Italian nun: b. Florence, Italy, April 23, 1552; d. there, Feb. 2, 1590. She entered the Dominican Order at Prato in Toscana, and became its prioress. Her wisdom made her widely known. She was canonized in 1746. Her festival occurs on February 13.

CATHERINE I (Russian, **EKATERINA ALEKSEEVNA**; original name, **MARFA SKAVRONSKAYA**), empress of Russia; b. near Dorpat (Tartu), Livonia (Estonia), (?) April 15, 1684; d. St. Petersburg (later Leningrad), May 17, 1727. She was the daughter of a peasant who died when she was a small child. Reared as a foundling at Marienburg by a clergyman named Glück, Marfa was instructed in the Lutheran religion. There she was married to a Swedish dragoon, who abandoned her when the Swedes evacuated Marienburg in 1702. When the Russians entered the city she fell into the hands of General Sheremetiev, who relinquished her to Prince Aleksandr Danilovich Menshikov. At the latter's house in Moscow Marfa was first seen by Peter the Great, who made her his mistress in 1703. Although illiterate, she had exceptional good sense, patience, and good nature. In 1708 and 1709 she bore the emperor the Princesses Anna (d. 1728) and Elizabeth, the first of whom became the wife of Charles Frederick of Holstein-Gottorp (and the mother of Emperor Peter III);

and the second became empress of Russia in 1741. Marfa was received into the Greek Orthodox Church in 1710 and rechristened as Ekaterina Alekseevna, and in 1711 Peter the Great, having divorced Eudoxia, his first wife, married her. Besides the daughters named above, she bore the emperor five more children, all of whom died early; the Princesses Anna and Elizabeth were declared legitimate. After marriage, Catherine was the companion of the emperor on most of his campaigns. When Peter, with his army, seemed irreparably lost on the Pruth in 1711, she saved his life and extricated his forces by bribing the leaders of their Turkish adversaries with her jewels. Afterward she received many proofs of the gratitude of her husband. In 1722 she was proclaimed his successor, and in 1724, in an impressive ceremony in the cathedral at Moscow, she was crowned empress consort. Later in 1724, however, she fell under the emperor's displeasure because of a too intimate relationship with Moens, the chamberlain of her household. Peter had the man decapitated and the severed head placed in her apartments as a warning. Menshikov had continued to manifest much attachment to her; and though he had been for some time viewed with disfavor by the emperor Catherine appealed to him for aid when her husband had recurrent attacks of illness, with intervals only marked by dreadful explosions of rage. With the aid of others a reconciliation with Peter was effected, and the empress and the favorite were laboring to strengthen their improving prospects when her husband died on Jan. 28, 1725. Catherine and Menshikov, together with their supporters, considered it necessary to keep the death of the emperor secret until, by judicious arrangements, they had ensured that succession to the throne would actually pass to the empress. Theophanes, archbishop of Plescow, swore before the people and troops that Peter, on his death bed, had declared Catherine alone worthy to succeed him in the governing of the country. She was then proclaimed empress and autocrat of all the Russias, and the oath of allegiance to her was taken anew. During her short reign Menshikov was her principal counsellor. Nevertheless she desired to curb his power, and to this end established a supreme privy council in which a leading figure was Count Pëtr Andreevich Tolstoi. In foreign affairs she relied largely upon the guidance of Count Andrei Ivanovich Ostermann, one of Peter's most able diplomats. The Russian Academy of Sciences was founded with her approval and support.

CATHERINE II or **CATHERINE THE GREAT** (Russian, EKATERINA ALEKSEEVNA; original name, Anglicized, SOPHIA AUGUSTA FREDERICA OF ANHALT-ZERBST), empress of Russia: b. Stettin, Prussia (later Szczecin, Poland), May 2, 1729; d. Saint Petersburg (later Leningrad), Nov. 17, 1796. Member of a petty German princely house, at the age of 15 she was taken to Russia by her mother, Johanna Elizabeth of Holstein-Gottorp, at the request of Empress Elizabeth, to be affianced to the Grand Duke Peter, the latter's nephew and designated heir. Her faith was changed from the Lutheran to the Greek Orthodox, and on Sept. 1, 1745, the marriage was celebrated at Saint Petersburg. The union was not a happy one, for Peter was mentally weak and she was endowed with uncommon strength of character. The ardor of her

temperament and the ill treatment of her vicious husband led her into errors which had the most injurious influence on her whole political life. The couple became estranged, and much scandal was associated with her at the imperial court because of her numerous lovers. With the death of the Empress Elizabeth in January 1762 Catherine's husband ascended the throne as Peter III. He lived in the greatest dissipation, and on such intimate terms with a lady of the court that it was generally thought that he would repudiate Catherine and marry his mistress. Catherine, at the same time, condoned his infidelities since he did not oppose her own love affairs. Because of Peter's irrational conduct there was a conspiracy among certain nobles to depose him, and to this plot Catherine gave her support. Count Grigori Grigorievich Orlov, Catherine's chief paramour, and his three brothers were leaders in the movement to place her on the throne, and through their influence the regiments of the guard were the first to swear allegiance to the empress when she presented herself to them at Peterhof on the morning of July 9, 1762. Peter was seized with his wife's connivance, and, having formally abdicated, he was taken in custody to the castle at Ropsha; there, a week later, he died under unexplained circumstances, though Aleksei Grigorievich Orlov, his chief custodian, is believed to have strangled him. Thereupon Catherine was proclaimed empress and was crowned at Moscow with great pomp. During her reign of 34 years Russia was greatly enlarged and her power strengthened. In 1767 the empress assembled in Moscow deputies from all the provinces to draft an advanced code of laws, but discord soon arose and the project had to be abandoned the next year. A Cossack adventurer named Emelyan Ivanovich Pugachev proclaimed himself Peter III in 1773 and excited a revolt in several provinces of eastern Russia, but the movement collapsed following his capture on Sept. 14, 1774. The empress directed her own foreign policy and, although German by birth, identified herself completely with the interests of Russia. Through her influence Stanislas II Augustus was made king of Poland in 1764, but that country's condition became anarchic and she joined with Austria and Prussia in effecting the three partitions of that country (1772, 1793, and 1795). Her armies waged war against the Turks from 1768 to 1772, and by the Treaty of Küchük Kainarja Russia gained free navigation of the Black Sea. Grigori Aleksandrovich Potëmkin, who had become Catherine's chief favorite in 1771, conquered the Crimea in 1784 and commanded the forces which, from 1787 to 1791, waged a second victorious war against Turkey. The Treaty of Jassy, concluded in 1792, still further strengthened Russia's might.

Catherine II has been equally censured and praised. With all the weakness of her sex, and with a love of pleasure carried to licentiousness, she combined the firmness and talent of a powerful sovereign. Two passions were predominant with her until her death—love and ambition. She was never without her favorite, yet she never lost sight of her dignity. She was distinguished for her activity, working with her ministers, writing letters to Voltaire and Denis Diderot, and signing an order to attack the Turks or to occupy Poland, in the same breath. She favored distinguished authors, and was particularly partial to the French. Baron Melchior von Grimm,

her literary agent at Paris, was sheltered by her in Saint Petersburg when driven from France in 1792 by the Revolution. She several times invited Voltaire to her court; and she proposed to Jean Le Rond d'Alembert that he finish the *Encyclopédie* at Saint Petersburg and undertake the education of the grand duke—her son by Peter III. Diderot visited her at her request, and she often allowed him the privilege of familiar conversation with her. By these means she gained the favor of the literati of Europe, who called her the greatest of rulers. In fact, she was not without claims to this title. She protected commerce, improved the laws, dug canals, and founded towns, hospitals, and colleges. Peter Simon Pallas and other naturalists and travelers visited Russia at her expense. She endeavored to put a stop to the abuses which had crept into the administration of the various departments of government; but she began without being able to finish. Her anxiety to enlighten her subjects ceased when she began to entertain the idea that the French Revolution had been brought about by the progress of civilization. Despite her good intentions, there is no doubt that at her death serfdom and general misery had increased in Russia. Her son succeeded her as Paul I.

CATHERINE DE MEDICIS, kà-trên' dē mā-dē-sēs' (Italian CATERINA DE' MEDICI), queen regent of France: b. Florence, Italy, April 13, 1519; d. Blois, France, Jan. 5, 1589. She was the only daughter of Lorenzo de' Medici, Duke of Urbino, and the niece of Pope Clement VII. The latter arranged her marriage in 1533 at Marseilles to Henry, second son of Francis I of France. Three of their four sons became kings of France in her own lifetime, and two of her five daughters married ruling monarchs. At the French court she flattered alike the Duchesse d'Etampes, her father-in-law's mistress, and Diane de Poitiers, the mistress of her own husband, though these two ladies hated each other. With the accession of her husband as Henry II in 1547 her influence was eclipsed by that of his mistress; and when her eldest son came to the throne in 1559 as Francis II her authority was surpassed by that of his uncles, François de Lorraine, Duc de Guise, and Charles, Cardinal of Lorraine. Her second son was still a minor on becoming king as Charles IX in 1560, and as regent during the next three years she was actual ruler of the kingdom. After he came of age in 1563 he continued completely under her domination, and her influence remained undiminished throughout his reign. Her policy was to secure the welfare of her family and preserve the unity of France, and to this end she labored to keep the balance between the Huguenots and the Guises. Wavering between the Guises on the one side, who had put themselves at the head of the Roman Catholics, and Louis I de Bourbon, Prince de Condé, and Gaspard de Coligny, the powerful leaders of the Huguenots, she was constantly obliged to resort to intrigues. She insured toleration for the Huguenots by the edict of January 1562; but when they seemed too powerful she ordered the assassination of Coligny and, when this failed, sanctioned the Massacre of Saint Bartholomew (see BARTHOLOMEW, SAINT, MASSACRE OF). With the death of Charles in 1574, her third son, who had been elected king of Poland the preceding year, became, in turn, king of France as Henry III. Despite the designs of her fourth son,

Francis, Duc d'Alençon (who became Duc d'Anjou), she continued to exert considerable influence at the French court. At her death France was in a state of complete dismemberment. Her manners were elegant, and she took a lively interest in the sciences and arts. She procured valuable manuscripts from Italy and Greece, and caused the Tuileries and the Hôtel de Soissons to be built. In the provinces, also, several castles were erected by her order, distinguished for the beauty of their architecture, in an age when the principles of the art were still unknown in France. Her daughter Elizabeth of Valois was married in 1560 to Philip II of Spain; and in 1572 her daughter Margaret of Valois became the wife of Henry III of Navarre (who ascended the French throne as Henry IV in 1589).

CATHERINE HOWARD. See HOWARD, KATHERINE (CATHERINE).

CATHERINE OF ALEXANDRIA. See CATHERINE, SAINT.

CATHERINE OF ARAGON, ār'a-gōn, first consort of Henry VIII of England: b. Alcala de Henares, Spain, Dec. 15, 1485; d. Kimbolton, Huntingdonshire, Jan. 7, 1536. The youngest daughter of Ferdinand and Isabella of Spain, in 1500 she was betrothed to Arthur, Prince of Wales, son of Henry VII, and she was married to him at Saint Paul's Cathedral, London, on Nov. 14, 1501. The prince died April 2, 1502, and a papal dispensation was obtained for her betrothal to the king's second son, Henry, now prince of Wales and heir apparent to the English throne. It was not until the latter's accession to the throne as Henry VIII that the marriage was celebrated, June 11, 1509, and she was crowned with her husband at Westminster Abbey 13 days later. He was then 18 years old and his queen 23, and this inequality of their ages and the capricious disposition of Henry were circumstances most adverse to the durability of their union; in fact, it seems surprising that Catherine should have acquired and retained an ascendancy over the affections of the king for nearly 20 years. The only one of their five children to survive was Mary (who became Mary I), and the lack of male issue proved a source of disquietude to him. Moreover, he wanted Anne Boleyn for his wife. She served as regent during the king's invasion of France in 1513, and she visited France with Henry in 1520, when the monarch met Francis I at the Field of the Cloth of Gold (q.v.). In 1526 Henry refused further cohabitation with her on the grounds that his marriage with his brother's widow was invalid, and in 1528 Cardinal Lorenzo Campeggio, Italian papal legate, was appointed by Pope Clement VII colleague with Cardinal Thomas Wolsey to hear Henry's suit for divorce. On June 21, 1529, during the court hearing in London, Catherine appealed to her husband in person before the colleagues, denying the court's jurisdiction and asking that the matter be referred to Rome. Campeggio subsequently adjourned the court, and the papal refusal of the appeal made to it caused the downfall of Wolsey and provoked Henry to create a national church separate from the Roman Catholic Church. On July 14, 1531, at Windsor, Henry finally left Catherine, who was separated from her daughter, Mary. Thomas Cranmer, archbishop of Canterbury, declared in 1533 that

her marriage to Henry was null and void; and with the king's marriage to Anne Boleyn, Catherine, no longer considered queen consort, was compelled to spend the rest of her life in close confinement. On March 23, 1534, Rome at last declared the marriage of Catherine and Henry to be valid, and to the end the queen refused to acknowledge her deposition. Her last years, spent in solitude at Buckden and Kimbolton, in Huntingdonshire, were occupied chiefly in prayer and needlework. Shortly before her death she wrote a letter to the king, recommending their daughter to his protection, praying for the salvation of his soul, and assuring him of her forgiveness and unabated affection. The pathos of this epistle is said to have drawn tears from Henry. He had never presumed to call the virtues of his injured wife in question, and she certainly acted throughout with eminent dignity and consistency. She was buried in Peterborough Cathedral.

CATHERINE OF BOLOGNA. See CATHERINE, SAINT.

CATHERINE OF BRAGANZA, brā-gān'zā, consort of Charles II of England: b. Villa Vicosia, Portugal, Nov. 25, 1638; d. Portugal, Dec. 31, 1705. The daughter of John IV, Duke of Braganza (king of Portugal from 1640), she was married to Charles II in London on May 21, 1662; her dowry included cession of Tangier and Bombay to England. She showed at first a natural resentment at the infidelities of Charles, but finding her bitter protests of no avail, she began to tolerate his mistresses—notably Lady Castlemaine and the Duchess of Portsmouth. As a Roman Catholic, she was viewed with suspicion. When Titus Oates (q.v.) was active she was accused of attempting to poison the king: Charles, however, stood by her and the danger passed away. The queen survived the death of her husband in 1685 and remained in England until 1692, when she departed for Portugal. During 1704-1705 she was regent for her brother, Peter II of Portugal, whose increasing infirmities rendered retirement necessary. In this position she showed considerable astuteness, carrying on the war against Spain with firmness and success.

CATHERINE OF GENOA. See CATHERINE, SAINT.

CATHERINE OF RICCI. See CATHERINE, SAINT.

CATHERINE OF SIENA. See CATHERINE, SAINT.

CATHERINE OF SWEDEN. See CATHERINE, SAINT.

CATHERINE OF VALOIS, vā-lwá', consort of Henry V of England: b. Paris, Oct. 27, 1401; d. Bermondsey, Jan. 3, 1437. She was the youngest child of Charles VI of France and Isabeau (Isabella) of Bavaria. In 1420 she was married to Henry at Troyes, and the next year she was crowned in Westminster Abbey. Their son became Henry VI. After Henry's death in 1422 she came under the influence of Owen Tudor, squire of an old Welsh family; an act passed in 1428 forbidding marriage with the queen mother without royal consent was apparently too late. She bore him a daughter and

three sons; Edmund, the eldest, became the father of Henry VII. After Tudor's imprisonment in 1436 Catherine withdrew to Bermondsey Abbey, near London.

CATHERINE PARR. See PARR, CATHERINE.

CATHERINE WHEEL, a window or compartment of a window of circular form, sometimes with radiating divisions or spokes, used in medieval buildings, called a rose, or marigold window. It is a memorial of Saint Catherine's martyrdom. The term is also applied to a kind of firework in the shape of a wheel, made to revolve automatically when lighted; a pin wheel.

CATHERWOOD, Mary Hartwell, American novelist: b. Luray, Ohio, Dec. 16, 1847; d. Dec. 26, 1902. She taught school prior to her marriage in 1877 to James Steele Catherwood. Her first book, *Cracque o' Doom*, appeared in 1881. Among her novels of French Canadian life were *The Romance of Dollard* (1889); *The Story of Tonti*; and *The Lady of Fort St. John*. Stories of the Middle West included *Old Kaskaskia* (1893) and *The Spirit of an Illinois Town* (1897). She also wrote historical works, among them *The Days of Jeanne d'Arc* (1897) and *Heroes of the Middle West* (1898).

CATHETER, kăth'ê-tēr, in medicine, a tubular instrument used to insert into a mucous canal or hollow organ, such as eustachian catheters for the internal ear, urinary catheters for the bladder, and nasal catheters for the nose.

CATHETOMETER, kăth-ê-tôm'ê-tēr, in physics, an instrument for the exact measurement of small vertical distances. Its usual form consists of a horizontal telescope which slides upon a fixed, graduated, upright post. The telescope is raised or lowered until its cross hairs coincide with one of the objects whose difference in height is to be determined, and the position of the telescope upon the graduated post is noted by means of a micrometer. The telescope is then brought to the elevation of the second object, in the same manner, and the difference in the two readings gives the desired difference in height. A cathetometer is especially useful for the measurement of two tubes of mercury or other liquids.

CATHODE, kăth'ôd, in physics and chemistry, the negative pole (opposed to the anode, or positive pole) of any portion of an electric circuit, such as a battery, electrolytic cell, or vacuum tube.

CATHODE RAYS. See ETHER; ELECTRON THEORY; MOLECULAR THEORY; RADIATION.

CATHOLIC APOSTOLIC CHURCH, a religious body which was founded in London, Eng. in 1832 by the Rev. Edward Irving (q.v.) and frequently referred to as Irvingite. It was a vision of religious ideas rather than a distinct theology, in which the subject of prophecy was important as well as the doctrine of the second advent. Irving maintained Christ's immunity from sin but stated that the humanity which Christ assumed was sinful. In addition to the faith in prophecy by fervent prayer the gift of healing was also claimed. A religious

group came into being, and churches were opened in England, Germany, and the United States, with an elaborate, formal service of worship. Irvingites were often members of other churches also; the ministry was conducted by persons of ordinary occupations. In 1936 there were 7 churches in the United States, with a total membership of 2,577.

CATHOLIC BENEVOLENT LEGION, a fraternal society for Roman Catholic laymen, designed to afford to the members facilities for intellectual improvement, social advancement, and such other advantages as are offered by similar non-Catholic fraternities. It was organized in 1881 and incorporated under the laws of the state of New York with 11 charter members. The organization has the approval of the archbishops and bishops in whose jurisdictions councils of the fraternity have been formed.

CATHOLIC CHURCH, a phrase signifying universal church, the whole body of true believers in Christ; but the term is commonly used as equivalent to the Roman or Western Church. Like most other words used in ecclesiology, the term "Catholic" was borrowed at first from the New Testament. It occurs in some editions of the Greek original—including that issued in connection with the last revision—in the titles prefixed to the Epistles of James, I and II Peter, I John and Jude, and is the word translated general in the King James Bible. The first to apply it to the church was the Apostolic Father, Ignatius of Antioch (q.v.). When he and his successors used it they meant to indicate that the church of which they constituted a part comprised the main body of believers, and was designed, as it was entitled, to be universal. In this sense, the church was opposed to the sects and separate bodies of heretics who had separated themselves from it and were now outside its pale. When, in the 9th century, the separation between the Eastern and Western churches took place, the latter retained as one of its appellations the term Catholic, the Eastern Church being contented with the word Orthodox, long used by the Russian emperors in their politico-ecclesiastical manifestos. When the Protestant churches separated from communion with Rome in the 16th century, those whom they had left naturally regarded them as outside the Catholic pale. They, on the other hand, declined to admit that this was the case, and the term Catholic Church is used in the English liturgy apparently in the sense of all persons making a Christian profession.

CATHOLIC CHURCH, Roman. By this name is designated the large body of Christians, united in doctrine and worship under the supreme jurisdiction of the pope, the bishop of Rome. (See PAPACY.) The members of this communion are wont rather to speak of it as the Catholic Church, but admit the term "Roman" in the sense that "to be Roman is to be Catholic and to be Catholic is to be Roman." They hold that their church alone possesses in its fullness the system of truths, laws, and practices for the worship of God which was instituted by Jesus Christ (q.v.). Hence a brief statement of Catholic teaching on the origin, nature, and properties of the Church of Christ is necessary in order to understand why

the Roman Catholic Church demands that all men submit to her authority as a teacher, divinely appointed to make known with absolute certainty the conditions of salvation.

For the convenience of the reader, this article is divided into the following sections:

1. Doctrine
2. Organization
3. History
4. Catholic Church in the United States
5. Catholic Education in the United States
6. Catholic Press in the United States
7. Catholic Church and Science

1. DOCTRINE. From the four Gospels, considered as trustworthy historical documents, we learn that Jesus Christ was certainly a divine messenger to all mankind, and that therefore all men are bound to receive His message with implicit submission. The doctrine which He teaches may be an enforcement of truths which man might have learned, however imperfectly, by the use of his natural powers, or may include new truths which his natural powers would never have discovered.

The Apostles.—As Christ did not remain on earth to teach all men in person, He chose a band of apostles, whom He commissioned to preach to all nations the truths He had taught them, promising His assistance unto the end of the world, and imposing upon all men, under penalty of losing their souls, the obligation of receiving His doctrine. The presence of the Holy Spirit was to preserve the apostles from error and keep them perfectly united in their teaching.

Besides the gift of infallibility (q.v.), He conferred on them jurisdiction over all believers, the right to govern with threefold power, legislative, judicial, and executive. Moreover, they were to sanctify men by certain religious rites, called sacraments (q.v.), and for this purpose received the gift of holy orders (q.v.). To Peter (see SAINT PETER), one of the 12 apostles was granted a primacy, not merely of honor, but of jurisdiction. On him was Christ's Church to be built; he was to feed the entire flock, the lambs and the sheep. By thus organizing a body to teach, govern, and sanctify men under the primacy of St. Peter, Christ founded a religious society, supernatural in aims and means, and He chose for it the special name, the Church. (See CHURCH.)

This society was to last even unto the day of judgment; its duty was to teach all men; wherefore the apostles appointed their successors and transmitted to them the authority received from Christ. As the primacy of St. Peter was the first foundation, necessary to ensure the unity and stability of the church, it too was to last forever. The power he received was for him and his successors. There never should come a time when the doctrine of Christ would be lost through corruption.

Christ's Church.—Whence we gather that there exists today a religious society, empowered to teach with certainty all the truths of Christianity, and that it is a visible body, united in its government and religious teachings. The members of this society submit to its infallible teaching by profession of the faith, to its sacred ministry by the reception of baptism (q.v.), and to its ecclesiastical rule by obedience. If all men are obliged to enter this society, it is evident that Christ provided some signs, notes or marks by which His church can become known to all

earnest inquirers, by which it can be distinguished from other associations. Christ intended that His church should be known by unity. It was to be one in faith, one in government, one in worship, and one in the charity uniting all its members. It was to be known by holiness. The church is holy in its Founder; in its aim to lead men to God; in its means of sanctification, in the heroic virtue of many members, and in the permanence of miracles among them. It was to be catholic; that is, conspicuously diffused everywhere. Finally it was to be apostolic. The governing and teaching body is the continuation of the apostolic body to which Christ gave His mission and with which He promised to remain until the end of time. Whoever is not in communion with the successor of St. Peter cannot possess union with the apostolic body. The obligation of becoming a member of the church is often expressed in these words: "Out of the Church, there is no salvation." They do not mean that all who die out of the visible communion are lost. God does not inflict punishment but for a willful fault, and those who without fault cannot see their obligation of joining the church are not to blame. If, however, anyone, knowing this obligation, refuses to comply with it, he puts himself out of the way of salvation. The same holds true for those who neglect to examine properly into a matter of so great importance.

Catholics hold that the marks of the true Church of Christ are found only in the church in which the bishop of Rome holds the primacy. The bishops of this church all over the world are the successors of the apostles, possessing the right to teach, to rule, and to sanctify. The gift of infallibility, that is, the right to declare that certain doctrines have been revealed by God, is not personal to each bishop, but belongs only to the whole body of bishops, whether gathered in general council or not. The consent of the universal church, according to Christ's promise, is a sure criterion of revelation. To the bishop of Rome, as the successor of St. Peter, belongs the primacy of jurisdiction over the whole church, complete, supreme, ordinary, and immediate over each and all the churches of the world, over each and all the bishops and the faithful.

Papal Authority.—In this primacy is included the supreme authority as teacher of the church, or the prerogative of papal infallibility. By virtue of a special supernatural assistance of the Holy Spirit promised to St. Peter and his successors, the pope cannot err when, as supreme teacher of the universal church, he defines a doctrine concerning faith or morals to be held by the whole body of the faithful. Only when these four conditions are fulfilled is the pope infallible: (1) he must speak not in his private capacity, not merely in his official character, but as supreme teacher; (2) the matter defined must concern faith or morals; (3) the judgment must be delivered with the manifest intention of commanding intellectual assent; (4) the definition must be given to the whole body of the faithful. It is clear that infallibility has absolutely no connection with the pope's personal qualities and is entirely distinct from impeccability, or incapability of sinning. The extent of papal infallibility is the same as that of the church's infallibility. It embraces all the truths that God has revealed as the object of faith, and extends

to other truths and matters of faith without assurance of which it would be impossible, or very difficult, to preserve the deposit of revealed truth.

Scripture and Tradition.—It follows from what we have hitherto said that whoever wishes to know Christ's doctrine must appeal to the living authority. The church as teacher, that is, the bishops now living in union with the pope, can alone tell us what doctrines were revealed. This knowledge is not acquired from new revelations, but with the assistance of the Holy Ghost (q.v.) from various sources, chief among which is the preaching of the Gospel, by which the doctrines of Christ are handed down as a sacred heritage from age to age. Thus, even if nothing had ever been written, we should have today, incorrupt and infallible, the means of preserving religious truth which Christ established, namely tradition. However, it was natural that those who were commissioned to teach should also set down their teaching in writing. Hence we possess many documents and monuments from which we learn what the church taught in past ages and what it now teaches; the truths revealed remain unchanged. Moreover, we learn from the church that God Himself provided, by means of men, certain writings, containing revealed truth, and gave them to the church for the instruction and direction of the faithful. (See BIBLE.) From it alone we learn what books have been so inspired and constitute Holy Scripture; the church alone can authoritatively interpret these writings. Tradition, therefore, is prior to the Christian Scriptures both in time and in thought. It is wider in its scope, for it embraces Scripture as an instrument by which tradition is handed down and, on the other hand, contains matters which are not in Scripture. First and principally, tradition teaches us the authoritative character of Scripture itself. Even were all the copies of Scripture destroyed, the living voice would still proclaim the entire Christian teaching. Catholics yield to none in their esteem of Holy Writ as the inspired word of God, but they so esteem it because of what they learn concerning it from tradition. The chief sources from which this tradition is learned are the acts of councils, the writings of the popes, of the fathers of the church, inscriptions, monuments, pictures, liturgies, rites, and pious customs, in a word, every way in which the church is wont to profess her faith. See also APOSTOLIC FATHERS; FATHERS OF THE CHURCH; TRADITION.

Chief Doctrines of the Catholic Faith.—Catholics believe in one, true, living God, the Creator and Lord of heaven and earth and of all things visible and invisible, almighty, eternal, immense, and incomprehensible; infinite in will and intellect, and in all perfection, who, being one, singular, absolutely simple and unchangeable spiritual substance is to be regarded as distinct really and in essence from the world, infinitely happy in and from Himself, and unspeakably elevated above all things that exist or can be conceived. He knows all things in the most perfect manner, by one all-embracing act of His intellect, from eternity to eternity ever the same. He knows his own being, all things that are possible, past, present, and future, and all things that are not and never have been nor will be, but which would be, if some condition were fulfilled. He is all-wise, all-holy, all-just, true, faithful, and bountiful. Moreover, in God as there is one divine nature, so there are three divine persons, Father, Son,

and Holy Ghost, really distinct from one another, perfectly equal to one another. Nevertheless there are not three Gods, but one God. The Father is unbegotten, the Son is begotten of the Father, and the Holy Ghost proceeds from the Father and the Son. (See also TRINITY, DOCTRINE OF THE). This one true God of His goodness and by His omnipotent power, not in order to increase His happiness, not to acquire perfection, but to manifest it by the good which He imparts to His creatures, in accordance with His absolutely free decree, at once from the beginning of time framed out of nothing as to the whole of their substance, two kinds of creatures, spiritual and material, the angels and the world, and then man, in whom spirit and matter were united. God preserves and governs by His providence all things that He has created.

To the angels He gave sanctifying grace and with it the power to merit eternal happiness by free service. Many of them rebelled and were cast into everlasting fire, the rest were confirmed in grace and admitted to the beatific vision of God "formed the body of the first man out of the slime of the earth." He created his soul immediately, as He creates the soul of every man; the soul is a spirit, endowed with intellect and free will, and immortal. All men are descended from Adam (q.v.) and Eve. Like the angels, our first parents were also raised to a supernatural state by the infusion of sanctifying grace into their souls, being made adopted children of God, destined to the enjoyment of the beatific vision. This is the principle of supernatural life, whereby man can produce works that merit a heavenly reward. Moreover, God bestowed on man other preternatural gifts: great powers of mind and infused knowledge, complete control of the passions, immortality, and exemption from suffering and decay. This original justice our first parents lost by mortal sin, that is, by a grievous, willful violation of God's law; in consequence of Adam's sin all of his descendants are deprived of those privileges, are conceived in original sin and cannot of themselves enter the kingdom of heaven.

To atone adequately for the grievous insult to God and to repair the evil done to mankind, the second person of the Trinity became man. Jesus is true God and true man, one Divine Person subsisting in two natures, divine and human, not by the conversion of divinity into flesh, but by the assumption of humanity unto God. He was born of the Virgin Mary, who was truly the mother of God and remained a virgin in conceiving and bearing her divine Son and ever after till the end of her life. By singular privilege of God through the merits of Christ, the Redeemer, the Blessed Virgin was preserved free from original sin (q.v.), that is, in the first moment of her conception, when her soul was created, it was endowed with sanctifying grace. By further privilege, she was never guilty of any actual sin, mortal or venial. See also MARY; IMMACULATE CONCEPTION.

Christ, the God-man, became our Redeemer not by the mere effect of His preaching and example, but by His bloody death on the cross. He made Himself our mediator with His Father, offering atonement for the sins of all men. This satisfaction is not applied to those who have use of reason without their free employment of the means ordained by Christ. He merited for us the remission of sins, sanctifying grace, and all other graces conferred on man. After His death. He rose again on the

third day, ascended into heaven, where He sits at the right hand of the Father, whence He shall come with glory to judge the living and the dead, and of His kingdom there shall be no end. He founded a church and confided to it the task of teaching His doctrines and applying to men's souls the means of sanctification. This church is the guardian and interpreter of revelation; for though the existence of God can be known with certainty by the light of reason, it has pleased the Divine Wisdom to reveal many natural truths, as well as all those regarding our supernatural life. This revelation is contained both in written books and in unwritten traditions. The books of the Old and New Testament, held by the church to be sacred and canonical, were written by the inspiration of the Holy Ghost and have God as their author. In matters of faith and morals, the true meaning of Scripture is that which is maintained by the church. All interpretations at variance with the unanimous consent of the fathers, when they speak as witnesses of tradition, are false and forbidden.

Whatever is presented to us by the church as revealed truth must be accepted by the free assent of the intellect, not because of its intrinsic truth seen by the light of reason, but on the authority of God who has given the revelation, and who can neither be deceived nor deceive. This divine revelation has been made credible by external proofs, especially by miracles and prophecies; yet as faith is a supernatural virtue, the act of faith requires the assistance of divine grace, enlightening the intellect and strengthening the will and making our act supernatural. Without faith there is no justification, but as God wishes all men to be saved, all receive, either proximately or remotely, the grace to believe. Among revealed truths some are mysteries that cannot be demonstrated by human reason, but must be believed. The demonstrations of reason cannot contradict revelation, hence any assertions of human science that are at variance with what the church teaches to be revealed must be false.

As grace is necessary for the beginnings of faith and even for the pious affection toward believing, so it is needed to make our good works deserving of a supernatural reward. Grace is needed even for the just to avoid sin. Final perseverance is a special privilege of dying in the state of grace. Apart from a special revelation, no one can know that he will receive this blessing. Without grace, however, it is possible to resist less urgent temptations and perform acts that have natural goodness; hence all works done before justification are not sins. According to Catholic doctrine, actual grace is a real influence exerted by the Holy Ghost upon the soul, but it does not destroy the free will of man. A grace may be fully sufficient for a supernaturally good act, but if a man refuses to act with it, the grace will not be efficacious. God will not save us without our cooperation. See also GRACE OF GOD.

Actual graces aid us to obtain habitual or sanctifying grace, that is, to be justified by the remission of original sin or of grievous actual sin. This sanctifying grace makes us like unto Christ, holy and supernaturally pleasing to God, and brings with it the infused virtues and the gifts of the Holy Ghost. There are many

grades of habitual grace; it may be increased by good works and, on the other hand, may be entirely lost by mortal sin. God in His mercy offers to man supernatural happiness and makes this offer known by the preaching of His church, which he accompanies by an interior stirring grace. When a man cooperates with this grace, he believes the truth with absolute certainty and is moved by the thought of God's love; he sees reasons to fear God's justice and throws himself on God's mercy, trusting in the merits of Christ; hence he conceives a love of God and a detestation of sin. Thus by the working of grace and the cooperation of man's free will, the way is prepared for justification; and, provided that man puts forth no obstacle, the Holy Ghost works this justification by infusing charity into his soul, thereby destroying sin. Thus purified, man enters on a virtuous life, hoping by the merits of Christ to enter heaven, but he has no absolute certainty of his salvation.

In the process of justification, the first grace cannot be merited at all; for no supernatural reward is due to natural acts. With the aid of grace, both sinners and just can merit further actual grace, but only congruously and not with any strict right in justice. The just, that is, those in a state of grace, can merit final perseverance congruously and, because of God's promises, can merit in justice the increase of habitual grace, eternal life, and increase of glory. By mortal sin, all merit is lost.

As a means of justification, Christ has entrusted to His church seven sacraments (q.v.), or sensible rites, instituted by Him to effect in the soul the grace which they signify. When the necessary conditions are placed, the sacrament works by its own efficacy and not through the piety of the minister nor of the recipient. The sacraments are baptism, confirmation, Holy Eucharist, penance, extreme unction, holy orders, and matrimony. Baptism and penance remit sin; the others cannot lawfully be received in mortal sin. Baptism, confirmation, and holy orders can be received only once, because they imprint on the soul an ineffaceable mark, called the sacramental character. All the sacraments, if properly received, give sanctifying grace or increase it, if already in the soul. Since the promulgation of the Gospel, justification cannot be obtained without baptism of water, which blots out original sin and all actual sin. Infants who die without baptism cannot enjoy the supernatural vision of God. In adults, when baptism of water cannot be received, pardon of sin can be obtained by the baptism of desire, which consists in a perfect love of God and a sorrow for sin, including, at least implicitly, the desire for the sacrament. Remission of sin is also granted to all who suffer martyrdom for Christ. Sins committed after baptism are remitted by the sacrament of penance (q.v.) in which the sinner confesses with contrition all his mortal sins to the duly authorized priests of the church, from whom he receives absolution. Sins are also remitted by perfect contrition, but the obligation of divine law requires that even then, if possible, they must be confessed. Penance pardons the guilt of sins confessed and repented of, infuses or increases sanctifying grace, remits eternal punishment, if it was due, secures actual graces to avoid sin in future, and may also remit, wholly or in part, the temporal punishment still to be

undergone for sins the guilt of which has been pardoned. The whole punishment is not always remitted with the fault; for the remaining debt, satisfaction is made to God by sufferings patiently borne or voluntarily inflicted. For this purpose also the church has the power of granting indulgences which are not a remission of sin, much less a permission to commit sin, but the remission of the whole or part of the temporal punishment which may be due for sins, after the guilt has been pardoned. See also *INDULGENCE*.

In the Holy Eucharist there is really and substantially present the Body and Blood, Soul and Divinity of our Lord Jesus Christ, under the appearances of bread and wine. (See also *EUCCHARIST*.) By the words of the priest at the consecration, there is effected a conversion of the whole substance of the bread into the Body and of the whole substance of the wine into the Blood, which conversion is called transubstantiation (q.v.). By force of the words, the Body is under the species of the bread and the Blood under the species of the wine, but in virtue of the natural connection and concomitance by which the parts of Christ are linked together, He exists whole and entire under each species and every part of the species. In the Mass (q.v.) there is offered to God a true, proper, and propitiatory sacrifice for the living and the dead. To offer up this sacrifice, Christ instituted a visible and external priesthood and the sacrament of holy orders (q.v.); the minister of this sacrament must be a bishop, who has received the fullness of the sacred ministry. The various orders constitute the hierarchy. Priests cannot ordain or confirm. Other orders are the diaconate, subdiaconate, and the minor orders (acolyte, exorcist, lector, and ostiary). Before the minor orders, the tonsure is conferred as a sign of enrollment among the clergy, who are separated from the rest of the faithful, called the laity. The right to exercise the sacred functions within appointed limits is called jurisdiction; it is required for the lawful performance of all functions and for the validity of some. The Roman pontiffs have, by divine institution, universal jurisdiction. The other bishops have power to govern the dioceses to which they have been assigned by the pope.

Marriage between Christians was raised by Christ to the dignity of a sacrament. Its essence lies in the contract freely made between man and wife; the grace conferred is, first, an increase of sanctity, and, second, actual grace to fulfill the duties of the married state. The bond of Christian marriage after consummation is absolutely indissoluble. It is also exclusive: no man can have several wives, no woman, several husbands, at the same time. Those who, with the aid of God's grace, fulfill the obligations of virginity or celibacy live in a state more holy and better than the state of matrimony. From the fact that Christian matrimony is a sacrament, it follows that it has been entrusted to the church and is subject to the laws of the church, not to those of the state; hence the church has the power of assigning conditions necessary for the validity or lawfulness of the contract between those who have been baptized. See also *MARRIAGE*, *THE LAW OF*.

The means of sanctification are given to men to enable them to live and die in the state of sanctifying grace. At the hour of death each soul is judged by Christ and, if in mortal sin,

is condemned to hell to be punished by eternal torments, varying in intensity according to the degree of guilt. Those who die free from all sin, mortal and venial, and from all the temporal punishment for sin, are admitted at once to life everlasting, to perfect beatitude in the vision of God. The saints and angels in heaven offer up prayers for men, and it is good and useful to invoke their intercession that we may obtain favors from God through Jesus Christ, who is our sole Redeemer and Saviour. Catholics honor and venerate the saints and angels, and especially the Blessed Virgin Mary, because God loves and honors them, and because of their own personal sanctity; not, however, with the supreme worship that belongs only to God. Because of their special connection with holy persons, honor is also given to relics of the saints, to images and paintings of Christ and His saints. If men die in venial sin, or temporal punishment be still due, their souls are detained in purgatory (q.v.) until expiation is made. In this state they can no longer merit for themselves, but can be assisted by the prayers and good works of the faithful and particularly by the holy sacrifice of the Mass. The church has the power to apply indulgences for their relief. In addition to the particular judgment, immediately after death, there will be a general judgment at the end of the world. The body will rise from the grave reunited to the soul, and share for eternity either happiness in heaven or punishment in hell.

The chief duties of Christian life are expressed in the Ten Commandments of God and the commandments of the church. Many laws have been imposed by the church on particular classes or for special purposes; all Catholics, however, are bound, under pain of mortal sin, to hear Mass and rest from servile work on Sundays and holydays of obligation, to fast and to abstain from certain food on the days appointed, to confess all mortal sins at least once a year, and to receive the Holy Eucharist during the Easter time.

A Catholic must believe all the truths God has revealed and teaches through His church. Denial of one such would mean either the denial of God's veracity or of the church's infallibility. But it is not necessary that he should know explicitly more than the principal truths; all others are included in his acceptance of the church as a divine teacher, alone capable of declaring what truths are contained in the *deposit of faith* handed down from the apostles. The definition of a dogma by the church brings no change in doctrine; for no truth once taught as of faith is ever given up nor can any point be added which was not contained, at least implicitly, in the original teaching. However, the church's infallibility is not limited merely to revealed doctrines; she can also speak infallibly on matters necessary to safeguard revealed teaching. Belief in such decisions is called ecclesiastical faith. Outside the domain of divine or ecclesiastical faith, there are many subjects of pious belief among Catholics. Some of these may perhaps belong to the deposit of faith, but they are not yet authoritatively proposed. Others depend on human testimony, and are accepted with that degree of certitude which the testimony warrants.

In the expression of revealed truths and in the defense of faith from the charge of conflict

with demonstrated truths of science and philosophy, the church makes use of terms derived from the philosophy current among its subjects. Thus it has come about that the dogmas are expressed in the terms of scholastic philosophy and officially in the Latin language. As its doctrines can be taught in any language, so, too, the expression of them may be harmonized with whatever is found to be true in any system of philosophy.

In the worship, liturgies, discipline, and practices of the church, some regulations may be of divine origin, others are of ecclesiastical origin, and still others arise from the voluntary piety of individuals. Besides the ordinary obligations of Christian life, the church invites those of her children who feel the call from God to bind themselves by vow to His service. The principal vows are those taken to observe the evangelical counsels of poverty, chastity, and obedience. Those who have thus bound themselves in approved congregations or religious orders are called *religious*. (See ORDERS, RELIGIOUS). As a matter of discipline, all those in sacred orders in the Latin portion of the church are bound to observe celibacy. In the Greek portion today, no priest can marry, but married men may receive holy orders, except episcopal consecration.

2. ORGANIZATION. Supreme jurisdiction resides in the pope; the bishops are the rulers of dioceses, which are subdivided into parishes or missions under a parish priest or rector, assisted by curates. The dioceses are united into provinces, over each of which is an archbishop or metropolitan, the other bishops being called his suffragans. The archbishop convokes provincial synods (q.v.) hears certain appeals from the episcopal court, watches over the observance of ecclesiastical law in some particulars, and, under certain circumstances, appoints an administrator when a suffragan dies. The rank of patriarch is now only honorary. The pope is represented in some countries by apostolic delegates, to whom are referred appeals from the lower courts and through whom the pope sends his communications. In some countries there are apostolic nuncios, who deal directly with the various governments that have their representatives at Rome.

The pope is assisted immediately by the sacred college of cardinals and by the sacred congregations. The college of cardinals, when complete, contains 70 members: 6 cardinal bishops of the suburban sees, 50 cardinal priests, and 14 cardinal deacons. The sacred congregations, 12 in number, are committees of cardinals to whom special affairs are entrusted. They were arranged almost as at present, by Pope Sixtus V. The cardinals alone cast votes for the final decisions, but they are assisted by secretaries and consultors. The pope himself acts as prefect of some congregations (the Holy Office, the Oriental Church and the Consistorial). A cardinal presides over each of the others. The acts of all congregations are submitted to the pope for his approval. These acts, unless promulgated in a solemn manner as the acts of the sovereign pontiff himself, are subject to change; though not infallible, they must be received by the faithful with an internal assent, such as is due to religious authority and obeyed as laws of the church. The more important congregations are: the Holy Office (the

supreme tribunal to guard the teaching of faith and morals), the Consistorial (which selects the matters that are presented and sanctioned by the college of cardinals assembled in the papal consistories), the Congregation for the Oriental Church, and the Congregation *De Propaganda Fide* (which cares for missionary countries), the Congregation of Sacred Rites, the Congregation of the Council, to which is committed the universal discipline of the secular clergy and the Christian people, and the Congregation for Extraordinary Ecclesiastical Affairs. See also CANON LAW.

The Church and Civil Authority.—The church was established by Christ as a perfect, independent religious society. Its authority depends on God's ordinances alone; wherefore it has always denied any right on the part of the state to interfere in its internal affairs. In Catholic countries, the church claims immunity for its officials from the authority of civil tribunals; in past ages this immunity was often absolutely necessary for their just protection. Sometimes the pope makes a concordat with temporal rulers; that is, a treaty whereby, in consideration of certain promises of these rulers, the pope abstains from urging certain of his rights. To exercise the prerogatives which we have described, the pope, his cardinals, and other officials must be exempt from the jurisdiction of any civil tribunals. Practically this cannot be secured without the temporal power (q.v.), or better, the temporal independence of the sovereign pontiff. It is not enough for the pope to be free, he must be known to be free; suspicion of being under the influence of a sovereign would be fatal to his influence. This independence he possessed for more than 15 centuries; it was assured by the recognition of his sovereign authority in the states of the church. From the annexation of these states by the Italian government in 1870 to the conclusion of the Lateran Treaty in 1929, by which an independent Vatican City with the pope at its head was set up, the popes proclaimed the seizure of the states of the church an act of injustice; that the pope did not possess the freedom, security, and independence necessary for the proper exercise of his authority; that the Holy See must insist on these facts and look forward to some efficient remedy. To deal rightly with Catholics of all nations, the pope must be extranational. As the seat of the United States federal government, the District of Columbia, is independent of all the states, so the seat of the general government of the church should be independent of all the countries of the earth.

3. HISTORY. The history of the Roman Catholic Church may be divided into three great epochs: (1) Christian antiquity, embracing the first seven centuries, during which Christian civilization was chiefly Greek and Roman, (2) the Middle Ages, from the 8th century to the 16th, characterized by the church's action among the various peoples of north and central Europe, who were molded into organized nations by her influence; (3) the modern age, from the rise of Protestantism to the present day, during which the Germanic nations separated from the church and attached themselves to various sects, and the church has had to struggle against the modern, infidel spirit in science and government.

The first epoch contains two periods. First comes an era of persecution, during the struggle

with paganism, which was terminated by the Edict of Milan (313); then, an era of development in definitions of dogma against the attacks of heresy. The second epoch embraces four periods: (1) the conversion of the barbarians; (2) the development of the Western Empire and the church's struggle to maintain her independence (800–1073); (3) the supremacy of the church maintained (1073–1300); (4) attacks on the church's supremacy, from Boniface VIII to Protestantism.

During the third epoch three periods may be distinguished: (1) the period of religious warfare, ending with the Treaty of Westphalia, 1648; (2) from 1648 to the French Revolution, the era of established churches; (3) down to the present day: neopaganism in science and life, the age of unrestrained freedom to accept or deny the truths of religion.

Even while the church was undergoing cruel persecution, she was also developing her discipline and defending her doctrines against the pagans and heretics. From the first three centuries have come down to us the valuable works of Ignatius of Antioch, Polycarp, Justin, Clement of Alexandria, Origen, Tertullian, Cyprian (q.v.), and many others. The mightier struggle with heresy, and her marvelous growth after she emerged from the catacombs, gave renown to Athanasius, Basil, the Gregories in the East and West, Chrysostom, the Cyrils, Hilary, Ambrose, Jerome, Augustine, Leo (q.v.), and a host of other Christian writers, of whose works the modern world knows very little. The growth of monasticism is one of the glories of this age. Monks and nuns consecrated their lives to God's service by prayer and study and labor, thus preserving the ancient civilization from utter destruction by the barbarians, and preparing for the church the means of converting these barbarians and transforming them into the civilized communities of Europe. The intimate union which existed between church and state gave rise to the Holy Roman Empire (q.v.) and to the great body of laws by which their mutual relations were regulated. Frequent attempts were made later to subject the church to the empire. They were frustrated by the popes, and especially by Gregory VII, after whom came the glorious period of vigorous life and eminent learning. Among the orders that were then founded we may mention the Carthusians, Cistercians, Franciscans, Dominicans, and Servites, fruitful in numerous saints and scholars. The church boasts of St. Anselm, Peter Lombard, Albertus Magnus, St. Thomas Aquinas, St. Bonaventure, John Duns Scotus, St. Bernard, and others. It was also the age of the Crusades (q.v.) for the recovery of Palestine. The 14th and 15th centuries are noted for the revival of interest in pagan literature, the sad exile of the popes at Avignon, and frequent movements to effect a much-needed reformation of morals. In this work, many rejected the divine authority of the church and were cast out as heretics; they are generally regarded as forerunners of Martin Luther (q.v.), who succeeded in separating whole sections of Germany from the church, and became the occasion for the Counter Reformation that was effected by men like Francis de Sales, Ignatius of Loyola, and Peter Canisius during the 16th century, and especially by the great work of the Council of Trent (1545–1563). In this same period, millions of pagans were brought into the church by the heroic labors

of her missionaries, notably in South America, India, Ethiopia, and Japan. England, under Henry VIII and Elizabeth, renounced the supremacy of the pope, made a state religion of its own, and by the penal laws almost annihilated the Catholics. France remained Catholic, but, becoming infected with Jansenism and Gallicanism (qq.v.), and later with atheism and socialism, brought about the utter disorganization of Continental society. In the reconstitution of the shattered nations, Napoleon (q.v.) thought to make the papacy his tool, and thus ruin the church; but he failed, and the 19th century witnessed the gradual revival of the church in almost all European countries, and its stupendous growth in the United States and other English-speaking countries. Catholic emancipation in England (1829), the Tractarian movement (see TRACTARIANISM) in the Established Church, that resulted in so many converts to Rome, and the restoration of the Catholic hierarchy (1850), gave Catholics prominence in English life. In France, though the people are loyally Catholic, the government engaged in controversy with the church and in the attempt to control Catholic education. When the French garrison was withdrawn from Rome in 1870, the Papal States and the city of Rome were annexed and added to the Italian kingdom. From 1870 to 1929 the pope never left the Vatican Palace. Shorn of their earthly kingdom, Pope Pius IX and Leo XIII (qq.v.) witnessed the attempt of Bismarck (q.v.), in Germany, to subject the Catholic Church to the state; but they witnessed also the failure of the attempt and the repeal of almost all the iniquitous laws. Persecution served only to unite all Catholics and revealed to them the power of united action. In continental United States the church grew from 244,500 in 1820 to 24,402,124 in 1946. This great increase was due mainly to immigration from Europe and Canada. Irish, Germans, French Canadians, Italians, Poles, and Bohemians have come in large numbers. Meeting with no official opposition, the church has prospered and is regarded by many non-Catholics as a strong power for the preservation of the republic from the new social dangers that threaten the United States as well as the whole civilized world.

The activity of the church in the mission field was almost destroyed by the wholesale confiscations of the French Revolution. As soon as order had been established in Europe, the missions revived, and especially since Gregory XVI, have spread to every land of the world. Dioceses are mapped out and bishops appointed as soon as the circumstances warrant. The reorganization of the Congregation De Propaganda Fide by Pius IX, with separate sections for the Latin and the Oriental churches, has been of great advantage. College, institutes, and special religious congregations have been founded in various cities of Europe for work in the foreign missions. The Society for the Propagation of the Faith is the largest of the societies among the laity for the collection of funds. Missions are also conducted with success in the Oriental churches in communion with the Holy See. These churches hold the same doctrines as the Latin church, but have special rites, discipline, and liturgical language. There are four chief groups: (1) the Greek, subdivided into Greek proper, Melchite, Slav (which is Ruthenian and Bulgarian) and Rumanian; (2) the Syrian, subdivided into Syrian proper, Syro-Chaldean (which also included the Malabar),

and Maronite; (3) the Coptic, which is Egyptian and Abyssinian or Ethiopian; (4) the Armenian. Pope Leo XIII was much interested in these Eastern churches, and had the joy of receiving many converts into communion. For bibliography, see article CATHOLIC CHURCH IN THE UNITED STATES.

(J.J.W.)

Recent Growth and Statistics.—In 1945 the Catholic Church contained within its fold over 393,400,000 members, or approximately one half of the entire Christian population of the globe. It is found in all continents and among all nations but is strongest in southern countries and among the Latin and Celtic races in Italy, Spain, France, Austria, Ireland, and South America. Its history during the 19th century discloses the remarkable fact that while it lost somewhat on its own ground, especially in France and Italy, these losses have been more than offset by the gains throughout the English-speaking world, especially in the United Kingdom, the United States, and Australasia. In England the conversion of Newman, Manning, and others was the beginning of a movement which brought and still brings thousands into the Catholic Church.

Pope Pius IX took official cognizance of the movement by re-establishing the Roman Catholic hierarchy in England in 1850. The growth of the church in Holland led to a similar re-establishment of the hierarchy there in 1853. The Irish emigration to Scotland after 1847 led to a great increase in the number of Catholics in that country, where the Oxford movement also exerted considerable influence; and in 1878, Leo XIII re-established the Catholic hierarchy there. Great and numerous, however, as were the gains in the Old World, they were greatly overshadowed by the vast growth and spread of the church in the New World and in the British dominions overseas.

No one can estimate precisely the number of Roman Catholics there are in the world. Statistics have regularly been given, but those familiar with the different locales and certainly those acquainted with the reliability of statistics have not found existing estimates trustworthy. The number of Catholics reported for some countries, particularly in southern Europe, is generally exaggerated, while in the case of other regions of the world Catholic statisticians believe that the reported data underestimate the actual number of Catholics. This is particularly true for the United States. The best statistics discoverable were prepared by Reverend Albert J. Nevins, a Maryknoll priest, and suggest that in 1945 there were 393,413,888 Catholics in the world. The distribution of these Catholics was as follows: Near East, 691,387; central and north Asia, which includes Mongolia and Manchuria, unknown; India, Burma, and Ceylon, 4,000,000; southeastern Asia, which includes Indochina, Siam, and the Malay States, 1,489,010; China, 3,500,000; Japanese Empire, which includes Korea, Formosa, and the mandated Islands, 283,491; North and Northeast Africa, 1,500,000; East Africa, 1,500,000; West Africa, 1,500,000; Central Africa, 3,000,000; South Africa, 500,000; insular South Africa, 1,000,000; North America, 30,000,000; Central America, 28,500,000; South America, 83,000,000; Australia and New Zealand, 1,850,000; East Indies, 600,000; Pacific Islands, 500,000; Philippine Islands, 10,000,000; Europe, 220,000,000.

The number of Catholics in the chief countries of Europe at the close of World War II was estimated as follows: England, 2,259,104; Czechoslovakia, 10,800,000; Belgium, 7,968,431; Netherlands, 2,293,563; Portugal, 5,612,000; Hungary, 7,131,398; France, 29,000,000; Italy, 43,513,329; Switzerland, 1,677,317; Spain, 25,000,000; Eire, 2,773,920; Germany, 45,000,000. In North America, there were approximately 4,986,552 Catholics in Canada and 19,400,000 in Mexico.

The Official Catholic Directory for 1947 reports that there were 25,268,173 Catholics in the United States, Alaska, and the Hawaiian Islands. These statistics are not completely reliable since they are based upon voluntary parochial reports. The writer, by the use of current birth and death rates, estimates that there were approximately 30,000,000 Catholics in the United States in 1940. He further concludes that more than half of these Catholics resided in what is known as northeastern United States, while the southeast contained but a little more than 1,000,000 Catholics.

The hierarchy consists of four cardinals, 18 archbishops, 98 diocesan bishops, 1 vicar apostolic, and 18 titular bishops, serving as auxiliaries.

The 1947 *Directory* lists a total of 39,980 ordained priests, most of whom belong to the diocesan clergy.

Priests belonging to religious communities include 3,472 Jesuits, 1,425 Benedictines, 2,159 Franciscans, 923 Redemptorists, 950 Dominicans, and thousands more in smaller communities. Professed religious included 6,721 brothers and 139,218 sisters, of whom 61,916 nuns were engaged in works other than teaching. There were, in 1946, a total of 14,523 parishes in the United States, Alaska, and Hawaii, of which 13,583 had resident pastors. In addition, there were 5,124 chapels, 5,084 missions, and 2,316 stations where Mass is offered more or less regularly. The total number of separate educational institutions (11,150) included 59 diocesan seminaries, 273 seminaries, scholasticates, and novitiates, 211 universities and colleges for men and women; 7,493 elementary parish schools, and 543 private elementary schools. There were a total of 22,950 seminarians, 102,655 college students, 477,090 high school students, 2,146,813 elementary school students. The total number of Catholic hospitals was 692 with a bed capacity of 86,919. In the year 1945 there were 87,430 American converts to the Catholic Church.

4. CATHOLIC CHURCH IN THE UNITED STATES. The Catholic Church came to that part of the New World destined to become the United States with the first explorers. Whether the discovery of America by a European be credited to Christopher Columbus, or to Leif Ericsson five centuries earlier, or to some explorer of an intermediate epoch, it can safely be asserted that the discoverer was a son

of the Church. The English ships venturing to the New World at the close of the 15th century were commanded by Catholics, John and Sebastian Cabot; and in 1502 Mass was said on American shores by an English priest.

The first all Catholic settlement was Spain's at St. Augustine, Fla. (1565). In the 17th century France brought the faith to Louisiana and Indian missionaries journeying down from Canada into what is now Maine, New York, Michigan, and Illinois, represented further developments of early Catholicity here. The Spanish missionaries on the Pacific coast in the 18th century showed how much could be accomplished by such efforts among the Indians when unhampered by the exploitation of the whites. As the result of the Franciscan missions, the Californian Indians, some of the lowest in the country, were in the course of a single generation lifted to a comparatively high level of civilization, living peacefully in their mission towns and occupying themselves with agriculture and domestic manufactures. They developed what amounted almost to genius in the arts and crafts and left monuments of architecture that are standing witnesses, now fortunately being carefully preserved, of the success of their Christian teachers to bring out all that was best in Indian nature.

As a rule, in the 13 original colonies, Catholics were proscribed. Even in Maryland, founded by a Catholic and whose proprietor, Lord Baltimore, had at its foundation proclaimed for the first time in history the practice of religious freedom, proscriptive laws were passed after a time, and Catholics were deprived of most of the rights of citizens. In New York under King James II, Thomas Dongan, a Catholic governor of the colony, granted a charter (1683) far more liberal than that enjoyed by any American colony up to that time, securing for everyone absolute freedom of worship; but after the fall of the Stuarts, Catholics in New York came under rather severe laws once more, so that as late as the middle of the 18th century John Ury, convicted of being a Catholic priest, though he was not, was put to death.

Pennsylvania was the only one of the colonies that tolerated freedom of worship for Catholics before the American Revolution, for even Maryland, founded by Catholics on the principle of religious tolerance, had so turned against that original liberal policy that when there was a question of building a Catholic church in Philadelphia, the project was for a time put off until there was a definite settlement of the dispute then pending, as to whether the land on which Philadelphia was built belonged to Maryland or Pennsylvania.

In spite of this intolerance of the colonists, a great many of the Catholics fought bravely for the colonies in the revolution, so that Washington particularly came to respect them thoroughly. Some, like Gen. Stephen Moylan, became his close friends, while the ardent patriotism of men like Commodore John Barry (q.v.) heartened the Father of his Country at some of the darkest hours of the war. Catholic toleration in Pennsylvania had its manifest good effect, a large proportion of the famous fighting Pennsylvania Line (the Line of Ireland, as Gen. Henry Lee called it) were Catholics. When Guy Fawkes' Day was to be celebrated in Boston with the burning of an effigy of the pope, Washington wrote a letter, still extant, suggesting how un-

suitable was such a celebration when Catholics were taking their parts wholeheartedly with the colonists. One of the important signers of the Declaration of Independence was Charles Carroll, a Catholic, who, when someone remarked that there were so many Carrolls that the British would not know exactly which one it was, designated himself beyond all doubt by adding "of Carrollton." Even John Jay's bigotry, though it alienated Canada, did not lessen the patriotism of Catholics in the colonies. The alliance (1778) with King Louis XVI of France did much to break down intolerance toward Catholics. Members of Congress from all over the country came to be on terms of intimacy with the French and Spanish ministers who had Catholic chaplains with them. Formal religious celebrations of successes in the American Revolution were held in St. Joseph's Church, Philadelphia, Pa., and attended by many prominent in the government of the country. All this helped to break down bigotry. Anne César de La Luzerne, the French minister, who pledged his private fortune to the help of the colonists, was a further important factor in the lessening of prejudice. He won the respect and friendship particularly of New England members of the Continental Congress and became a close personal friend of Governor Jonathan Trumbull of Connecticut, the Brother Jonathan, whose name became the popular symbol of the American people until replaced by Uncle Sam. Benedict Arnold's treason plot proposed, besides the surrender of West Point, a scheme to capture the French minister on one of his visits to Connecticut. Among the excuses alleged by Arnold in extenuation of his treason was that the Quebec Act had granted freedom of worship to Catholics in Canada, and the toleration of Catholicity which he saw was growing in the colonies endangered the Protestant religion. It has sometimes been said that the securing of toleration in the United States was more of an accident than a definite purpose. Anglican and Puritan could not trust each other, so Catholics slipped in under the general religious liberty which had to be voted. As a matter of fact, it seems clear now that the first amendment to the Constitution, guaranteeing religious liberty, was not a little due to Washington's influence and was carried because he wanted to safeguard the rights of the Catholics, whom he had learned to value highly for their heroic efforts for the country during the revolution. In spite of this amendment, however, the laws of many states continued to bar Catholic citizens from their rights. Pennsylvania and Delaware were the only states whose laws did not need expunging in order to secure to Catholics the right to vote and be voted for. In 1784, Rhode Island removed from its constitution the clause disqualifying Roman Catholics from office. This was before the adoption of the federal Constitution, but other states were slow to follow this example. In 1806, New York did so, but Massachusetts waited until 1821; Virginia, until 1830; North Carolina, until 1836. New Jersey did not remove all disqualifications from Roman Catholics until 1844, while in 1876, fully 100 years after the adoption of the 1st Amendment to the federal Constitution, New Hampshire still retained disqualifying laws, only repealed the following year. Shortly after the revolution, the church was organized independently of all foreign influence with John Carroll, (q.v.) a relative of the signer of the Declaration

of Independence, as prefect apostolic, appointed Nov. 26, 1784. Until the revolution, the Catholics in the colonies had been under the jurisdiction of Bishop Richard Challoner, the vicar apostolic of London. His successor refused to exercise any such jurisdiction. It was proposed at first that the church should be under French ecclesiastical jurisdiction, and Benjamin Franklin as American minister to France favored this for a time, but was brought to realize the danger there would be in such foreign influence. Carroll's appointment followed his recognition of this.

In his letter of acceptance, Carroll stated that there were at the time in Maryland 15,800 Catholics; in Pennsylvania 7,000; in Virginia 200; in New York 1,500; a few in New England; and some scattered along the Mississippi, formerly under the jurisdiction of the bishop of Quebec. Altogether there were less than 30,000 Catholics in the whole country. The infant church had some serious troubles, many of them due to what is known as the trustee system. Laymen in control of the funds thought to control also sacerdotal and even episcopal action. The spirit of independence in the new country readily tempted to abuses in this matter, and the first half century of Catholic history has many such disputes, which led to the loss by the church of a number of Catholics, especially of the older families. In 1789, the year of the organization of the government, Carroll was named bishop and consecrated in 1790, so that the state and the Catholic Church run parallel in their formal history. Bishop Carroll at once took up the project of a college, already discussed in 1786, and Georgetown College in the District of Columbia was founded in 1789. Bishop Carroll visited Boston, Mass., and noted with pleasure how the spirit of tolerance was growing: "It is wonderful to tell what great civilities have been done to me in this town where a few years ago the popish priest was thought to be the greatest monster in creation." Previous intolerance can be best understood from the fewness of the Catholic population in New England, for in 1798 the whole number of Catholics was estimated at only 750, this figure including some 500 Catholic Indians in Maine. In 1800, Reverend Francis A. Matignon erected the first building for Catholic services in Boston worthy of the name of a church, "John Adams, President of the United States, and other Protestant gentlemen being generous contributors." New Orleans, where there had been a bishop since 1793, was brought into the United States in 1803 by the Louisiana Purchase; and with it came a large increase in the Catholic population. The religious liberty assured in the country soon brought large numbers of Catholics and led a great many back to the faith which either they or their fathers had abandoned because of religious intolerance and the difficulty of practicing their religion. At Bishop Carroll's suggestion, new bishoprics were created in 1808 in Boston, Philadelphia, and Bardstown, Ky. He recommended that New York be left under the jurisdiction of Boston, but the Irish bishops succeeded in securing the appointment of Father R. Luke Concanen as bishop of New York. Bishop Concanen died before reaching the United States. Michael Egan was chosen bishop of Philadelphia; Jean Louis Lefebvre de Cheverus, bishop of Boston; and Benedict Joseph Flaget, of Bardstown. Baltimore then became an archbishopric. Arch-

bishop Carroll died in December 1815 and was succeeded by Archbishop Leonard Neale, who established the Visitation Convent at Washington, D.C., and restored the Jesuits (Society of Jesus), suppressed by the pope in 1773, but permitted to revive in 1814. Prince Demetrius Augustine Gallitzin of Russia, who had become a priest, did splendid missionary work in western Pennsylvania in the early part of the 19th century, founding in 1799 the town of Loretto, still famous as a Catholic center.

The American church was particularly fortunate in the bishops who occupied these first sees. Archbishop Carroll was a valued and respected friend of the patriots who made the country. Bishop de Cheverus (q.v.), the first bishop of Boston, had been doing heroic missionary work throughout New England for about 15 years before he was made bishop. He was often consulted by the legislature of Massachusetts and accepted many invitations to explain Catholic doctrine, making use for this purpose even of Protestant churches. Speaking of him, William Ellery Channing said: "How can we shut our hearts against this proof of the Catholic religion to form good and great men?" Bishop Flaget (q.v.), another Frenchman, the first bishop of Bardstown, was indefatigable in his missionary labors in the immense territory under his jurisdiction, later divided into 28 dioceses, five of them archdioceses. He won the respect and reverence of all who came in contact with him. The Bardstown bishopric was subsequently transferred to Louisville (1841). Bishop Joseph Rosati, an Italian, the first bishop of St. Louis, Mo., was another one of these marvelous pioneer bishops whose missionary spirit could not be satisfied. In one year his converts numbered 300. Bishop Mathias Loras became the first bishop of Dubuque, Iowa, in 1837 with but one priest to help him, and yet he succeeded in accomplishing immense good and stamping his personality on all the future history of Dubuque. Another very successful French bishop was Joseph Cretin, the first bishop of St. Paul, Minn. Some of the problems he had to meet will be understood from the fact that within a period of six years his flock grew from 1,000 to 60,000. Like Bishop Loras of Dubuque, he was very successful in promoting Catholic immigration and laying deep foundations for the future of his diocese. The bishops were of all nationalities. Frederic Baraga (q.v.), a Slovenian from the west of Austria, was appointed the first bishop of Marquette in 1853 after having labored for 22 years as a missionary among the Indians of Michigan. His writings are still recognized as of high authority on the languages of the American Indians.

The church continued to grow rapidly, particularly in the South and West, and two new bishoprics were created in 1820 in Richmond, Va., and Charleston, S. C. John England (q.v.) of Irish birth, destined to be a great power in the American church, was made bishop of Charleston. His writings are still a storehouse of information on Catholic subjects. The bishoprics of Cincinnati, Ohio, and Saint Louis, Mo., were erected in 1821 and 1826. It was felt that the growth of the church now demanded that the bishops and prominent ecclesiastics of the country should take council of each other for the benefit of Catholicity in America, and the first Provincial Council of Baltimore was held in 1829. The records show that at this time Catholics had in-

creased more than 12 times in numbers in the United States and that there was in 1830 a Catholic population of nearly 400,000.

New bishoprics continued to be founded in the West, and sees were erected at Dubuque in 1837, Chicago, Ill., and Milwaukee, Wis., in 1843, Oregon City, Oreg., 1846, St. Paul, Minn., and Santa Fé, N. Mex., 1850 and San Francisco, Calif., in 1853. Before the acquisition of California, San Francisco had been part of the Mexican diocese of the two Californias erected in 1840. During the decade after 1840, Catholicity increased very rapidly in the United States because of European immigration. The famine in Ireland and political troubles of various kinds in other countries caused a great many immigrants to seek the protection of the United States, and the church had to make provision for a very large increase in its membership. To deal with the new problem thus created, the First Plenary Council of Baltimore assembled in 1852. At this time the Catholic population numbered about 2,000,000; there were 30 episcopal sees including the six archdioceses of Baltimore, New Orleans, New York, Cincinnati, Saint Louis, and Oregon City. In New York and Boston particularly, Catholics increased rapidly in numbers. At the end of the first quarter of the 19th century there were some 15,000 Catholics in the diocese of Boston, about half of whom were in the city, but they were beginning to crowd into all the growing towns of New England: Lowell, Fall River, and Taunton in Massachusetts; Providence and Newport in Rhode Island; and Hartford, Conn. New York grew even faster. At the end of the first decade of the 19th century, Reverend Anthony Kohlmann, S. J., found the parish of Saint Peter's in New York City to contain 14,000 Catholics. He purchased a site for a second church between Broadway and Bowery Road, then on the outskirts, and with the coming of a bishop to New York this became the cathedral. Father Kohlmann who opened a school and was prominent in the intellectual life of the city was once summoned as a witness against prisoners accused of thievery and asked to tell what he had heard from them in confession. This he refused to do in a most solemn way in court, and the presiding justice, DeWitt Clinton, supported him, thus settling for America the question of the status of information obtained in confession as privileged. The second bishop of New York was John Connolly, consecrated in 1814. He was succeeded by John Dubois in 1826. At his arrival he estimated the Catholics in the city at 25,000 and throughout the diocese 150,000. To serve the spiritual needs of this immense number, New York City had only six priests and there were but four in the rest of the state. Albany, Rochester, and Buffalo, though each containing hundreds of Catholics, had no resident priests. Brooklyn had but one small chapel, a mission from New York, visited occasionally by a priest. Newark, Paterson, and New Brunswick, in New Jersey, all of them then in the New York diocese, were only building their small churches. Almost necessarily under such difficult conditions, a great many Catholics lost their faith because of lack of opportunities to practice their religion and bring up their children in it. Some of the Western dioceses were, of course, in even worse straits. Bardstown included besides Kentucky and Tennessee all the country known as the Northwest Territory, embracing what is now the

states of Illinois, Indiana, Michigan, Wisconsin, and Ohio. There were small scattered Catholic communities of French at Kaskaskia, Cahokia, Prairie du Rocher in Illinois; Vincennes, Ind., along the Raisin River and in Detroit and Mackinaw, Mich., at Sandusky, Ohio, and Green Bay, Wis., though there were only three priests to tend to them all. Bishop Flaget within 10 years was able to report that he had in Kentucky alone 19 churches, 10 priests, and 10,000 Catholics.

Pioneer Priests.—Some of the pioneer priests were remarkable men. One of these was Father Gabriel Richard, a Sulpician who did so much for Detroit and the neighborhood at the beginning of the 19th century. The Sulpicians, exiled from Paris by the French Revolution, were of great help to infant Catholicity in America. They founded St. Mary's Seminary in Baltimore (1791) which, after a very trying time at first, proved a wonderful nursery of priests for the American church. In 1831 they founded St. Charles College for clerical students though it was practically not opened until 1848. Father Richard was assigned to the missions in Illinois about 1795, transferred to Detroit in 1798. He opened a young ladies' academy in 1804 and a seminary for young men the same year. The girls were taught spinning and weaving as well as purely intellectual subjects. With Reverend John Monteith, pastor of the Protestant church of Detroit as president and Father Richard as vice president, the "Catholepistemiad or University of Michigan" was founded in 1817. In 1821 when the University of Michigan was incorporated, Father Richard was made a trustee. He published a precursor of the first Catholic paper in the United States, *The Michigan Essay or Impartial Observer* (1809). Before he was able to get the printing press over the mountains he had a public crier who as a "spoken newspaper" gave the news and certain advertisements at the church door on Sundays. In 1823 he was sent to Washington as territorial delegate, the only instance of a priest having a seat in Congress. When cholera visited Detroit in 1832, Father Richard, in his zeal for the sick, fell a victim to the disease. Judge Thomas M. Cooley (q.v.) declared "he would have been a man of mark in almost any community and at any time."

Archbishop Hughes.—One of the greatest of the Catholic prelates of the United States was John Hughes (1797-1864, q.v.) who became coadjutor bishop of New York in 1838 and the first archbishop of that see in 1850. A self-made man who worked his way through Mount St. Mary's College, Emmitsburg, Md., as a gardener, he demonstrated a high quality of intellect in his controversy with a Presbyterian minister, the Reverend John Breckenridge (q.v.), which made the American people realize for the first time how strong was the intellectual position of the Catholic Church. He showed his firm character during the troublous times of trusteeism in Philadelphia and then was made bishop of New York. He at once took up the correction of abuses that had crept into New York life to the detriment of the church. It was due to his efforts that the Public School Society, a private corporation which controlled the funds and managed the common schools of New York, was dissolved, to the lasting benefit of popular education. Bishop Hughes then inaugurated a system of parochial schools which has developed into the magnificent Catholic school system of New York. His con-

troversy with "Kirwan" (Reverend Nicholas Murray) in 1848 probably did more than anything else to make Americans understand how utterly one-sided were the commonly accepted views of the church in the United States. The firm stand that Bishop Hughes took in New York prevented the rioting, destruction and bloodshed, which occurred as a consequence of Native Americanism in 1844 in Philadelphia, and of Know-Nothingism 10 years later, in many parts of the country, from coming to a head in his diocese. See AMERICAN PARTY; KNOW-NOTHING PARTY, THE.

He was well known for his thorough-going devotion to the best interests of his adopted country, and was a personal friend of President Polk and of many men prominent in the political history of the time. During the Civil War he was appealed to by President Lincoln and Secretary of State Seward and was entrusted with a diplomatic mission of an informal character to Europe, particularly to France, in order to neutralize the growing sentiment in favor of European intervention on the side of the South. In spite of failing health which had compelled him to ask for a coadjutor, he accepted this mission at the personal solicitation of President Lincoln, had an interview with the Emperor Napoleon III in December 1861 and then proceeded to Rome, where, during many months, he met prelates from European countries and corrected many false impressions with regard to the American Civil War. The government at Washington felt that his visit to Europe had been of great importance in making the cause of the North better understood, and an official intimation of this was conveyed to the Holy See direct from President Lincoln, suggesting that the archbishop could only be properly rewarded by Rome, but his failing health put that out of the question. President Lincoln wrote a letter commending Archbishop Hughes' patriotism. The last public function that he undertook was a public address delivered shortly before his death to the Catholics of New York with regard to participation in the draft riots (q.v.) which caused so much disturbance to the city and country in July 1863. His address to the crowd had to be made sitting down because of his weakness, and his voice could not be heard far, but his published words made it clear beyond all doubt that the Catholic Church commended to its members their duties as citizens to fight for the conservation of the Union to which they owed so much.

Just before and after the middle of the 19th century the Catholic Church received great additions to its members by the immigration from Ireland, consequent upon the famine and intolerable conditions there, and from Germany because of political disturbances in connection with the revolutions of 1848. Undoubtedly the strongest American influence exerted over these newly arrived Americans was that of the church, and its effect was seen in the large numbers of Catholics of Irish and German descent who fought splendidly and so many of whom shed their blood in defense of the Union during the Civil War. There had been organized intolerance under the name of the Native American Party, which led to the burning of the Ursuline convent at Charlestown, Mass., in 1834, and of two Catholic churches in Philadelphia (1844) as the result of riots in which a number of people were killed. In the 1850's, the Know-Nothings, so called be-

cause of their answer to all questions about the organization, as directed by its rules, was "I know nothing," led to serious disturbances, including the killing of Catholics, the burning of churches and other outrages in some 10 states. The answer to this campaign of bigotry by the patriotism displayed in the Civil War was complete.

About the same time the church began to make large gains by conversion from among the educated people of the country. There was an "Oxford movement" in America as well as in England, and many distinguished converts were made. Among these the best known was Orestes Brownson, renowned as a writer on serious subjects, and Isaac Hecker (of Brook Farm), who gathered round him the group of men who founded the Paulist Congregation, New York, for the conversion of non-Catholics. There were a number of converts from among the Protestant clergy, the most distinguished of them being Reverend Levi Silliman Ives, the Protestant Episcopal bishop of North Carolina, Reverend Thomas Scott Preston of New York, Reverend James Roosevelt Bayley of New Jersey, Reverend George Hobart Doane, the son and brother of Protestant Episcopal bishops of New Jersey and Albany, and somewhat later, Reverend James Kent Stone, president of Kenyon and Hobart colleges, who afterward became Father Fidelis of the Cross of the Passionist Fathers.

The best proof of the recognition by church authorities that the church in the United States should be absolutely American in character and in sympathy with the republican aims of the country is to be found in the fact that a number of these converts were advanced to the highest posts in the hierarchy. James Roosevelt Bayley became bishop of Newark and later archbishop of Baltimore and is said to have been offered the cardinalate which he declined in favor of Archbishop John McCloskey of New York. Other converts who became bishops were William Tyler of Hartford, Edgar P. Wadhams of Ogdensburg, and James Frederick Wood of Philadelphia, who later became archbishop. Father Doane became vicar-general and chancellor of the diocese of Newark, Father Preston became vicar-general of New York, and both were made domestic prelates of the pope. Dr. Levi Silliman Ives was one of the founders and the first president of the Society for the Protection of Destitute Roman Catholic Children in the City of New York and was given as a layman distinguished opportunities for the accomplishment of great good. Many other distinguished converts were made, among them Dr. Jedediah Vincent Huntington (brother of Daniel Huntington, the artist) who wrote a series of Catholic novels; George Parsons Lathrop and Charles Warren Stoddard, poets; Edward Lee Greene, the botanist; Reverend Daniel Hudson of the *Ave Maria*; Molly Elliot Seawell and Frank Spearman, novelists; Rose Hawthorne, the daughter of Nathaniel, who afterward became Mother Alphonsa of the Servants of Relief for Incurable Cancer; Mr. and Mrs. Bellamy Storer; and such distinguished physicians as Drs. William Holme Van Buren, one of the leaders of the profession of New York City, William Edmonds Horner, professor of anatomy at the University of Pennsylvania, Thomas Dwight, Parkman professor of anatomy at Harvard University for 25 years, Thomas Addis Emmet, of international fame in

his specialty of women's diseases, Horatio Storer, former vice president of the American Medical Association and well known for his contributions to American medical literature. The number of conversions grew each year after the middle of the 19th century and increased in the 20th century. It is calculated that about 25,000 converts are received annually into the church. Perhaps the best evidence that the church appeals to thoroughly practical men as well as to those of spiritual and intellectual tendencies is to be found in the fact that altogether of men who reached the rank of brigadier or major general in the Civil War, 46 became converts before their deaths.

The Catholic population of the United States had been growing very rapidly during the decades just before the Civil War. The newly made citizens faced their duty to their adopted country bravely and with few exceptions wholeheartedly. Archbishop Hughes more than any other gave the keynote to patriotism for his fellow countrymen of the North. The archbishop of New York had long considered that slavery was a blot on the United States, and as a young man at college in lyrical mood had invoked Columbia to "chase foul bondage from her Southern plain." In his controversy with Breckenridge he had pointed out the absurdity of paying a compliment to our "memorable Declaration of Independence," coupled with an allusion to slavery. He had taken firm ground against the radical abolitionists, however, pointing out that they had committed the very crime of attempting to overthrow the Constitution and government of the United States which they charged against the Southern Confederacy and urging moderation and conciliation on both sides. Once war was declared, however, there was no halfheartedness about his support of the Union.

Another of the distinguished prelates of the second half of the 19th century was Archbishop Martin John Spalding (1810-1872), a descendant of a family that had been in the United States for many generations. He became bishop of Louisville in 1850 and archbishop of Baltimore in 1864. The growth of the church, and above all the number of conversions had attracted public attention more than ever to Catholicity. The patriotism of Catholics during the Civil War had moderated much of the intolerance felt toward the church, and Americans were now more willing to listen to expositions of Catholic doctrine. Archbishop Spalding responded to a deeply felt want by his lectures in many parts of the country and by the breadth of his scholarly erudition succeeded in placing the church's position properly before the minds of fair-minded Americans. He was the first to suggest the establishment of a Catholic university and to insist that intensive development of the intellectual life would add greatly to the church's position. He came to be held in high esteem by prominent men of all classes and sects in the United States. When the Second Plenary Council of the church in the United States met at Baltimore in 1866 under the primacy of Archbishop Spalding the Catholic population had doubled to nearly 4,000,000, and though the increase was very largely due to Irish and German immigration, the feeling was growing throughout the country that the new citizens were being trained to genuine Americanism under the influence of the church whose hierarchy was deeply patriotic in its policies.

Two distinguished prelates who have been called Fathers of the American Church were the Kenricks—Irish by birth but thoroughly American in their influence on the church. Francis Patrick Kenrick was for a time bishop of Philadelphia (1830), and was transferred to the archbishopric of Baltimore in 1851. He was honored by his fellow citizens of Philadelphia for his courageous zeal during an awful epidemic of cholera and for his tact during the native American riots when 40 persons were killed in the city. His brother, Peter Richard Kenrick, became archbishop of Saint Louis in 1847 and lived to celebrate the golden jubilee of his consecration. His firm stand with regard to the Drake test law led to a decision by the United States Supreme Court which prevented threatened infringement of the constitutional guarantee of religious liberty.

In 1884 when the Third Plenary Council was held, under the primacy of Archbishop (later Cardinal) James Gibbons, the Catholic population had actually doubled once more to 8,000,000. The new primate, Cardinal Gibbons, was destined to occupy a place of particular affection in the hearts of the American people and to be looked upon as a typical representative of all that was conservative in American life. His published opinions came to be looked upon as almost national messages, always read with attention and considered with reverence. The church continued to grow rapidly under the favoring influence of religious liberty and doubled once more in numbers by the beginning of the new century.

Religious education came very early to be recognized as an extremely important factor for the church's growth in the United States and for the conservation of the spirit of Christianity. The Catholic hierarchy was firmly persuaded, to use Herbert Spencer's words, that "it works grave mischief whenever intellectualization precedes moralization." The first Catholic college, that of Georgetown, was established in 1789, the very year of the organization of the Union. Other colleges followed. Catholic higher education for women began with the establishment of the Visitation Academy, Georgetown, D. C., in 1799. Mother Elizabeth Seton's organization of the Sisters of Charity and the foundation of Saint Joseph's Academy, Emmitsburg, Md., followed in 1809. The first institution for giving anything more than education in the ordinary branches to girls in New England was the Ursuline Academy in Charlestown, Mass., opened in 1834 and, though mainly attended by the children of Protestant parents, was burned down that year by a mob from Boston at the risk of the lives of some of the pupils.

For statistics on Catholic education in the United States, see *CATHOLIC CHURCH, ROMAN—Recent Growth and Statistics*; *CATHOLIC EDUCATION IN THE UNITED STATES*.

After education, the church considers its most important work the organization of charity. The oldest hospital founded by private beneficence still in existence in what is now the United States is the Charity (Sisters) Hospital at New Orleans, La., dating from 1720. In 1829 four Sisters of Charity went to St. Louis from Emmitsburg to open the Mullanphy Hospital, which had been endowed by John Mullanphy. In 1832 when an outbreak of cholera in Blockley Hospital, Philadelphia, utterly disorganized that hospital, six sisters, by request of Bishop Kenrick, started

from Emmitsburg within two hours after the summons and took charge, restoring order there and giving the institution "its one short interregnum of peace in the distressing reign of violence, neglect and cruelty." (Nutting, M. A., and Dock, L. L., *History of Nursing*). In 1847, Mercy Hospital, Pittsburgh, Pa., was founded, to be followed by a chain of hospitals under the care of the Sisters of Mercy throughout the country. In 1849, St. Vincent's Hospital, New York, was established by the Sisters of Charity. Carney Hospital, Boston, was founded in 1868. Sisters' hospitals have come to occupy a prominent place in American life, there being some 690 Catholic hospitals in the country. The sisters also have charge of the orphans, of the foundlings, of a number of institutions for the old, as well as for the insane and the tuberculous. Mother Cabrini (St. Frances Xavier) founded a series of hospitals, beginning with Columbus Hospital, New York, 1892, orphan asylums and schools in the country for the Italians, which have helped very much in solving the social problems connected with this large group of new citizens.

For details of Catholic missionary activity in the United States, see *MISSIONS, ROMAN CATHOLIC*.

Toward the end of the 19th and the beginning of the 20th century the church in the United States received large additions to its number through the immigrants from the Slav countries. Slav Catholics in the United States numbered approximately 5,000,000 (1948).

This large foreign immigration to America has introduced a series of new problems and elements into the political life. They are not very different from those which occurred as a consequence of German and Irish immigration at the middle of the 19th century. The church was an important factor in the transformation of these European stocks into American citizens of sterling patriotism. Her ministrations under the direction of a hierarchy that has shown itself thoroughly American and free from any political bias that might hamper free development, is accomplishing a similar transformation for the Slavs and the Italians. President McKinley declared the influence of the Catholic Church in this matter as extremely precious for the future welfare of the country. The decided stand taken by the church against all the forces of anarchy has meant much for preserving the balance of conservatism among newly arrived peoples, so liable in the first flush of their enjoyment of liberty to go too far in what they expect of it.

Roman Catholic societies organized to foster social aims, provide fraternal insurance, and organize public opinion against abuses and immoralities of various kinds play an important part in American Catholic life. They include the Holy Name Society, organized to discourage blasphemy, but doing social work of many kinds, which counts a membership of a million. The Legion of Decency, established in 1934, to raise the moral and intellectual level of motion pictures; the Society of St. Vincent de Paul (q.v.), and the temperance societies which flourished in the last decades of the 19th and first two decades of the 20th centuries. The National Councils of Catholic Men and Women, with headquarters in Washington, D. C., integrate the various Roman Catholic organizations in the United States.

For Catholic population in the United States see section 3. of this article.

5. CATHOLIC EDUCATION IN THE UNITED STATES. The first schools within the present limits of the United States were those founded by the Franciscans in Florida and New Mexico. St. Augustine, Fla., had a classical school as early as 1606, and there were a number of schools in existence for the natives of New Mexico in the year 1629. Schools for the natives were likewise established in Texas and California, with the foundation of the missions in those regions. Ursuline nuns from France established a parish school and academy in New Orleans, La., in 1727 a few years after the foundation of the city. French schools, for both white and native children, were also opened at St. Louis, Mo., Detroit, Mich., and other settlements to the north. In general, it may be said that Catholic school work usually began in a place, whether it was a white or an Indian settlement, as soon as there was a sufficient Catholic population and organization to furnish support for the school. In the East, the Jesuits in Maryland had opened schools by 1650, and a college or "school for humanities," was established there in 1677. Later on, a boarding school was opened at Bohemia, on the Eastern Shore of Maryland. Among the famous pupils of this institution were John Carroll and Leonard Neale, who subsequently became archbishops of Baltimore, and Charles Carroll of Carrollton, one of the signers of the Declaration of Independence. Georgetown College was founded in the year 1789. A more favorable opportunity for educational work was offered to the Jesuits in Pennsylvania, owing to the tolerant attitude of the Quakers, and, with the organization of the first Catholic parish in Philadelphia in 1730, the

foundation of schools as a regular and permanent feature of parish work may be said to have begun. Philadelphia had a larger Catholic population than any other town in the country, and the system of schools that was gradually established there and throughout Pennsylvania, as new parishes were organized, became a model to Catholics elsewhere. A new impulse was given to Catholic education by the American Revolution. Catholic immigrants came in increasing numbers, and learned priests, exiled by the French Revolution, arrived opportunely to take up the work of organizing parishes, schools, and colleges. In 1791 the Sulpicians founded St. Mary's Seminary at Baltimore. Foremost in Catholic educational work west of the Alleghenies were Fathers Stephen T. Badin and Charles Nerinckx in Kentucky, Father Gabriel Richard in Detroit and other places in Michigan, and Father Edward Fenwick, a Dominican, first bishop of Cincinnati, in Ohio. What was accomplished in these three states had a very important influence in the development of Catholic education throughout the whole Middle West later on. During the period 1800-1840 the progress of Catholic education, while slow, was steady and solid, and corresponded with the growth of the church. Catholic textbooks began to appear, and, more important still, religious sisterhoods were organized to carry on the work of teaching in the schools. The first teaching sisters in the English-speaking states were the Poor Clares, who opened a school at Georgetown, D. C. in 1801. This order soon discontinued educational work; but in 1812 an American branch of the Visitation Order was founded at the same place by Bishop Neale. Mother Elizabeth A. Seton (q.v.), under the direction of Father Louis Guillaume Du Bourg, organized the Sisters of Charity at Emmitsburg, Md., in 1809; this community grew rapidly and furnished teachers to Catholic schools in all parts of the country. Shortly afterwards, three teaching communities were founded in Kentucky—the Sisters of Loretto, the Sisters of Charity of Nazareth, and the Sisters of St. Dominic. These teaching communities rendered it possible for Catholics to carry on their schools and academies without aid from the state and to extend the educational system to new centers of Catholic life as fast as they became organized. Among the religious orders of men, the work of the Lazarists and Jesuits during this period deserves particular mention, the latter having laid the foundations of St. Louis University, Mo., in 1828. Another great forward movement in Catholic education originated in the tide of immigration that set in about the year 1840. Hundreds of thousands of Catholic Irish and Germans made their way to the Middle Western states and beyond. Zealous priests and bishops of the newly created dioceses labored to erect everywhere not only churches but schools. After the failure of Bishop John Hughes of New York to secure for the Catholic schools of that city a share of the public educational funds, although his efforts were warmly seconded at Albany by Governor William H. Seward, it was more keenly realized by Catholics that it had become a matter of religious necessity for them to erect and maintain their own schools and that, as Bishop Hughes declared, "In this age and country the school is more necessary than the church." At the instance of the bishops, many new teaching communities came from Europe, and their member-

ship was rapidly augmented under the favorable conditions offered for religious and educational work. The result was that, while in the year 1840 there were only about 200 parish schools in the country, this number was multiplied several times over during the ensuing decade. Academics for girls were established by the Ladies of the Sacred Heart and other sisterhoods, while the Christian Brothers took the lead in the field of secondary education for boys. Colleges and seminaries, also sprang up. The Jesuits carried their work of higher education into every section of the country by founding colleges and preparatory schools. A later phase of the immigration movement resulted in the establishment of schools for French-Canadians, Poles, Italians, Bohemians, and other nationalities. Of these, the Polish schools are the most numerous.

School Organization.—In accordance with the church's organization, Catholic elementary education is framed along diocesan lines. Each diocese has its school system, with the bishop at its head. Bishops, however, are bound by the legislation of the Third Plenary Council of Baltimore, which prescribed a definite form of school organization for all the dioceses. General legislation has thus operated to give a certain measure of unity to parish-school work the country over, while local needs and interests are left to be provided for by the diocesan authorities. Diocesan control over the schools is usually exercised through the diocesan school board, presided over by the bishop. The members are selected from the clergy of the diocese; in some places the laity are included. In the prevailing type of school organization the school board includes, as its executive officer, a diocesan superintendent of schools. The priest who is selected for this office is specially trained for his work; he devotes his time to the inspection of schools and to the study of the problems involved in their improvement, and his recommendations are embodied in an annual report submitted to the school board. As assistants to the superintendent, there are in many dioceses community inspectors of schools. As a rule, there are many teaching orders engaged in any given diocese, and when each community appoints one of its members to inspect and study the work that is being done in its own schools in the diocese, the result is to give the superintendent a corps of zealous and efficient assistants through whose co-operation his recommendations may the more easily be given practical effect. In the case of the individual parish school, the pastor is, of course, by right its head; but, generally speaking, beyond supervising the religious instruction and financial matters, he leaves the direction and control of the school to the superior of the sisters or brothers in charge. The actual principal of the school is therefore the immediate religious superior. The teachers usually live in or near the school building, which is in close proximity to the parish church. About nine tenths of the teachers in the parish schools are religious. Male teachers are less than one fifteenth of the total number. Nearly 300 distinct communities are engaged in the work, including single independent houses as well as congregations. Of these, 11 are teaching brotherhoods. The curriculum of the parish school does not, as a rule, show any substantial difference from the curriculum of the neighboring public schools, except in the matter of religious instruction.

The training course for religious teachers embraces the postulate, the novitiate,* and the normal school. In the postulate are included the elements of a good common school education and some high school work; during the novitiate—generally of one year—study is continued, but the chief aim is the religious formation of the candidate. In the normal school, proximate preparation is made for the work of teaching, through suitable pedagogical studies, while more advanced academic courses, sometimes leading to the college degree, are also taken up. Such is the training course that obtains in the more progressive communities; in many instances, however, this ideal program is not strictly adhered to in practice, owing to the demand for teachers. But the tendency is steadily toward higher standards. Much has been accomplished in this direction through the work of summer institutes and summer schools conducted especially for teachers by colleges and universities. Worthy of special mention in this connection is the Sisters' College, at the Catholic University of America, Washington, D. C. Many sisterhoods are now sending picked young teachers to this institution for college and university courses as well as normal school training. Money for the support of the schools is obtained from three sources: tuition fees, the parish treasury, and endowments. The amount derived from the last-mentioned source is practically a negligible quantity, except in the case of a few favored schools. The tuition fee was long the prevailing source of school revenue, but it has been replaced to a great extent by the simpler and more direct means of support, the parish treasury, especially in the cities and larger towns. Schools thus supported are called free schools. In many places, in accordance with the practice in public schools, textbooks are also supplied free. The salaries of sisters engaged in parish-school work probably average \$50 per month, or \$500 per year. Brothers who teach in the parish schools generally receive from \$600 to \$750 a year. Teachers in Catholic schools thus receive less than one half the salary of public-school teachers of the same class, and in many parts of the country they receive barely one third as much. Yet out of their slender salaries the religious teachers have not only to maintain themselves, but also to save something as a contribution to the support of the mother house and its various establishments, such as the training schools, the infirmary, and the like. Only by the practice of the strictest economy, joined to the most devoted personal self-sacrifice, are the members of religious communities enabled to accomplish these objects successfully. As might be inferred from the above data, elementary education in Catholic schools costs less than one half as much as elementary education in public schools. The actual cost per capita of Catholic elementary schooling throughout the country averages only about \$26 a year.

Alongside the parish-school system there have been developed secondary schools or high schools. These belong to several distinct types: the college preparatory school; the parish high school—an adjunct of a particular parish school; the diocesan high school, under the control of the bishop; and the independent high school, conducted by a religious order and more or less independent of diocesan control. There is a strong movement toward the more general establishment of diocesan high schools, since these form

an integral part of the diocesan school system and thus contribute more effectively to the unification of Catholic educational work. Notable among institutions of this class, for their typical character and influence, are the Boys' Central High School and the Girls' High School in Philadelphia.

An important agency in the changes that have been brought about in Catholic education in the direction of more perfect organization has been the National Catholic Educational Association, which was organized in 1904, and includes three main departments—elementary schools, colleges, secondary schools, and seminaries.

School Enrollment.—In the year 1945 there were 8,097 Catholic elementary schools (parochial and private) in the United States with an enrollment of 2,086,794 pupils, and with about 60,000 teachers. The number of pupils in 2,128 high schools and academies was 420,707, with a teaching staff of about 25,000. Investigation has shown that the total actual enrollment in Catholic schools is not quite one half that which the Catholic population of the country should normally supply. This means that about the same number of Catholic children go to the public schools as go to the parish schools. There are over 200 Catholic industrial schools; many girls' schools furnish instruction, in the upper grades, in practical household subjects.

Included in the total school enrollment are 262 schools for colored children, with an enrollment of 56,185. A number of teaching communities devote themselves especially to this work, several of these being composed of colored sisters. These schools, as a rule, derive their support from general church collections and gifts from generous individuals. There were also 67 schools for the education of Indians, with 7,628 pupils. There are 16 Catholic schools for the deaf, with an enrollment of approximately 1,700. According to official figures there were in the United States in 1945 a total of 10,697 Catholic schools of all grades. These institutions employed a total of 100,758 teachers, and were attended by a total of 2,688,271 students.

Colleges.—From an enrollment of approximately 16,000 students in 1916, the attendance at Catholic colleges and universities increased to 148,515 in 1945. The movement toward the development of universities, which has been characteristic of the progress of American higher education, has affected many of the larger Catholic colleges. Eighty-two institutions now have at least one professional department, while quite a number have several professional departments, in addition to postgraduate courses of study. Pre-eminent among Catholic institutions of higher education in the United States is the Catholic University of America, Washington, D. C., which is under the direction of the bishops, and which has a large postgraduate attendance and many affiliated institutions. One hundred and eighty-three institutions are conducted by the religious orders. Catholic colleges and universities are, as a rule, self-supporting; only a few are even partially endowed, with the exception of the Catholic University of America. Religious professors receive no salary, the services they render being entirely gratuitous; hence the college, being free to a great extent from the heavy financial burden of professors' salaries, is able to devote the revenue derived from student fees to its general expenses. Lay professors are not ex-

cluded, but their number is relatively small, except in a few instances. There is, however, a tendency to increase the number of lay professors; many of the colleges are endeavoring to raise endowment funds, largely with this end in view, and considerable success has attended these efforts. The gratuitously rendered services of the religious professors at the Catholic college or university are therefore equivalent to an endowment fund and in many instances its amount will compare favorably with the endowment of non-Catholic institutions.

(J.E.C.)

Seminaries.—The name "seminary" is applied by the Catholic Church specifically to institutions in which candidates for the diocesan (secular) priesthood receive their spiritual and intellectual training. Seminaries came into being at the command of the Council of Trent (1545-1563). The term is also commonly used for similar institutions conducted by religious congregations for the education of their own members.

There are two kinds of seminaries: major and minor, or preparatory. Minor seminaries give a four year high school and two-year college course in general academic subjects. In the major seminary, which is usually a separate establishment, candidates are trained for six more years in a curriculum centering in philosophy and theology. During the years of theology, the seminarian receives minor orders, and the major orders of subdiaconate, diaconate, and priesthood. His studies include dogmatic, moral, and pastoral theology, Scripture, apologetics, church history, canon law, liturgy, social sciences, homiletics, and sacred chant.

Seminaries are directed according to norms prescribed by the Code of Canon Law. The bishop of the diocese provides for and supervises his seminary in all things pertaining to government, discipline, temporal administration, and studies. A rector is the immediate superior, and the majority of professors are priests especially trained for the purpose. Ultimately, all seminaries fall under the supervision of the Congregation of Seminaries and Universities at Rome.

The first Catholic seminary in the United States was St. Mary's Seminary in Baltimore, Md., opened on Oct. 13, 1791. It was founded at the request of Bishop John Carroll of Baltimore, who obtained four members of the Society of St. Sulpice as a faculty. This society of secular priests had been founded in France in 1642 for the express purpose of training priests. In 1805 the Maryland legislature granted a university charter to St. Mary's. Its department of philosophy is located at the original site, while the theological students are housed in buildings opened at Roland Park, Baltimore, Sept. 30, 1929. Its minor seminary is St. Charles College, Catonsville, Md., which received its charter in 1830. There are approximately 900 seminarians in these institutions, taught by 58 priests. For many years, St. Mary's was the only institution of its kind in the United States, and during this period it supplied the church with the majority of the priests trained there.

The Sulpician Fathers also conduct the Theological College of the Catholic University of America in Washington, D. C. They have charge of St. Patrick's, the major seminary of the archdiocese of San Francisco in Menlo Park, Calif. Mount St. Mary's Seminary, Emmitsburg,

Md., was founded in 1808 by the Reverend John Dubois of the Sulpicians; it is now conducted by diocesan priests.

The major seminary of the archdiocese of New York is St. Joseph's Seminary and College, dating from 1864. It was established in Yonkers, N. Y., in 1897, replacing the old provincial seminary at Troy, N. Y. St. John's Boston Ecclesiastical Seminary for the Boston archdiocese was founded by Archbishop John J. Williams in 1884. It is located at Brighton, Mass., and is directed by diocesan priests.

The Theological Seminary of St. Charles Borromeo, Overbrook, Pa., is the major seminary of the archdiocese of Philadelphia. It traces its origin to 1835, when Bishop Francis P. Kenrick placed five students under the care of his brother, Reverend Peter Kenrick, in a small house in Philadelphia.

As a general rule, the largest and most influential seminaries of the United States are found in the various archdioceses of the country. Diocesan priests have been placed in charge of St. Francis Seminary at Milwaukee, Wis.; the St. Paul Seminary of St. Paul, Minn.; Mount St. Mary Seminary of the West at Norwood, Ohio, for the archdiocese of Cincinnati; and Immaculate Conception Major Philosophical Theological Seminary, Darlington, N. J., for the archdiocese of Newark. The faculty of St. Mary of the Lake Seminary, Mundelein, Ill., of the archdiocese of Chicago, comprises both diocesan priests and members of the Society of Jesus.

Priests of the Congregation of the Mission (better known as Vincentian Fathers) have been very active in training candidates for different archdioceses. They conduct The St. Louis Roman Catholic Theological Seminary (Kenrick Seminary) in St. Louis, Mo.; St. Thomas Theological Seminary in Denver, Colo.; St. John's Seminary at San Antonio, Texas; and St. John's Seminary at Camarillo, Calif., for the archdiocese of Los Angeles. At the Seminary of Our Lady of Angels, part of Niagara University (founded 1856), Niagara Falls, N. Y., priests are trained for the diocese of Buffalo. For many years priests for the diocese of Brooklyn received their training at St. John's University, Brooklyn, N. Y.

Notre Dame Seminary in New Orleans, La., is in charge of the Marist Fathers. Monks of the Order of St. Benedict train many diocesan priests in abbeys located in different parts of the United States. Important among them are St. Vincent's Archabbey at Latrobe, Pa., St. Meinrad's Abbey, St. Meinrad, Ind., Conception Abbey, Conception, Mo., and St. John's Abbey, Collegeville, Minn. Similar work is done by the Franciscan Fathers at St. Bonaventure's College, St. Bonaventure, N. Y., and St. Francis Seminary, Loretto, Pa.

The only seminary in the United States directly subject to the Congregation of Seminaries and Universities in Rome is The Pontifical College Josephinum, founded by Msgr. Joseph Jessing at Columbus, Ohio, in 1888. It is now located in Worthington, Ohio; its priests may be sent to any diocese in the United States after their ordination.

In 1920, the Society of the Divine Word established St. Augustine's Mission House, a college and seminary at Bay St. Louis, Miss., to train Negro candidates for the priesthood. In 1937 the bishops of the United States founded

Montezuma Seminary at Las Vegas, N. Mex., to educate Mexican students for the dioceses of their home country. This seminary is directed by priests of the Society of Jesus. In Europe two institutions are maintained by the American bishops for the training of American students, the North American College in Rome and another at Louvain, Belgium.

In 1947, there were 60 diocesan seminaries, major and minor, in the United States, with about 7,600 students, in addition to 3,500 diocesan candidates in religious seminaries. Seminaries of all kinds (novitiates, scholasticates) maintained by religious orders for their own students totaled 278, with an enrollment of 12,720 students. The total number of seminarians in the United States was about 23,700 in 1947.

(J.P.K.)

Summer Schools.—The first Catholic summer school, called the Catholic Summer School of America, was organized in New York State in 1892. After several years of trial it was established permanently at Plattsburg, N. Y., and was continued there until 1942, when it was suspended because of war conditions. In the meantime, other schools of a more formal type began to develop. During the summer of 1945 there were 135 of these schools, located in every part of the United States. Of these, 129 were special summer sessions, normally six weeks in length, while six were part of a trimester program. The main purpose of the summer session is to afford Catholic teachers an opportunity to obtain more professional training, to earn credits for higher degrees, or simply to maintain alertness in their respective fields. Usually courses are offered in all departments of the school, on both graduate and undergraduate levels. A maximum of six hours of credit can ordinarily be earned in a six weeks' session. Upon the successful completion of the required courses, a bachelor's or a master's degree can be obtained. To expedite the attainment of these degrees, many schools offer to their students a chance to do supplementary work during the regular school year by late afternoon or Saturday classes. Other types of Catholic summer schools, known variously as work shops, institutes, or conferences are being developed. Sponsored by the larger schools, they usually have for their purpose an intensive study of some particular phase or problem of education. These vary in length from a few days to six weeks.

(M.J.MCK.)

STATISTICAL SUMMARY (1945)

(Authority: National Catholic Welfare Conference, Department of Education)

Catholic population of the United States	25,268,173
Seminaries	238
Universities and Colleges	196
Teachers' colleges and normal schools	38
Secondary schools	2,128
Elementary schools	8,097
Enrollment	21,970
	148,515
	10,285
	420,707
	2,086,794

6. CATHOLIC PRESS OF THE UNITED STATES. Like many other American institutions, the American Catholic press had heroic beginnings in pioneer days, almost heart-breaking struggles to survive as it grew up, and finally emerged into a hard-bitten permanence that is deeply rooted, strong, and (in the mid-20th century) still in vigorous development.

This press began with the very early days of the republic: one precursor of the American Catholic newspaper was founded before George Washington first took office as president; a priest established a paper only nine years after the national capital was set up; the first Catholic magazine was launched while Charles Carroll, Catholic signer of the Declaration of Independence, was still alive. Many of the initial efforts were short-lived. Nevertheless, in the first 50 years, valiant work was done and a few of the journals then established were still published in 1948. In the next 40 years, there were numerous foundings and a high mortality among Catholic press units, but following the Civil War, some hardy publications began to survive. With the next 40 years, a flowering began as the reward of perseverance; once rooted, an increasing number endured. After 1920, a remarkable growth in numbers and variety was experienced; circulations multiplied, giving material soundness and a real durability of life.

In 1947 the Catholic press of the United States could boast 399 publications—aside from thousands of purely local bulletins of parishes, societies, and individual schools and institutions. There were 144 newspapers with a circulation above 4,000,000, and 255 magazines with 10,000,000, giving a circulation total of roundly 14,000,000.

Formative Years (1789–1839).—Struggle, determined, persistent and spirited, must be the characterization of the Catholic press in this period of pioneering. At times the effort was brilliant; at times, grim, but always willing and alert. It was an era of vicious attacks on Catholicism in the United States and in Europe. Extravagant charges, based on what are now generally recognized as prejudice and ignorance, were rife. It was to meet these that Catholic journals were first established, and it was because of these that they were often sharply controversial, sometimes polemic. They did not retort in kind with attacks on Protestantism. Rather, they conducted with vigor and insistence what Paul J. Foik, C.S.C., historian of this era, describes as “nothing more nor less than a gigantic struggle for the civil and religious liberty of the people.” With the conviction that misconceptions of Catholic teachings were at the root of the strife, the Catholic journals devoted themselves to clearing away these erroneous ideas. The ablest Catholic

paper in the period prominently displayed these words from the 1st Amendment to the Constitution: “Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof.”

The first strictly religious Catholic publication in the United States was the *United States Catholic Miscellany*, founded June 5, 1822, by the brilliant John England, bishop of Charleston. It was so sanely and, at times, so brilliantly conducted that it endured until the Civil War. The first Catholic magazine was the scholarly *Metropolitan*, established at Baltimore, Md., in 1830, which persisted only one year. Before and after these “firsts,” no fewer than 39 other journals flashed into (and most of them out of) existence in this initial half century of the nation, if we include precursors. This despite the paucity of Catholics in the early United States, and the acute meagerness of presses. Catholic publications appeared in 14 cities, not only in the two great national centers of population, New York and Philadelphia, but also in Baltimore, Bardstow, Ky., Boston, Charleston, Cincinnati, Detroit, Hartford, Louisville, Milwaukee, St. Albans, Vt., St. Louis and Washington, D. C. Of the 41 publications founded, 33 were almost ephemeral, but two of the newspapers still existed in 1948. No magazine and but one annual survives. One other paper lasted into the 20th century; two were stilled by the Civil War.

While Catholic publications of actual religious character were not established until 1822, there were earlier journals that were Catholic in tone or sympathy, and under Catholic guidance, even though not definitely Catholic in content. The first of these was the *Courier de Boston*, begun in April 1789, edited by a Harvard University instructor, Paul Joseph Guérard de Nancrède, and continuing half a year. In 1809, there appeared momentarily in Detroit the *Michigan Essay or Impartial Observer*, fostered by the enterprising missionary Father Gabriel Richard. The pioneer Boston effort was in the French language; the first issue of the *Michigan Essay* contained a column and a half in French, and there is record of two more semi-Catholic French papers in this period. There also appeared, in 1824 in Philadelphia and later in New York, a Spanish magazine, *El Habanero*, not professedly Catholic, but containing articles on ecclesiastical subjects and conducted by the remarkable Cuban priest and patriot the Very Rev. Dr. Felix Varela. It persisted only two years, but its tireless editor launched two other short-lived publications and edited or was coeditor of four others.

By far the most interesting national newspapers were the long series of Irish journals. These began in 1810 and had Catholicity and Ireland for their chief topics. They were essentially political and Irish rather than religious publications. Not only as a matter of race, but also of religion, the Irishmen who came to America in those times were compelled to defend themselves. Their zeal for their church was not exceeded by zeal for their native land or love of liberty. Thus there started, with the *Shamrock or Hibernian Chronicle* of New York, a succession of a dozen or more publications with Catholic and Irish defense as their objectives. These Irish journals were hard-hitting and a valuable resistance to the bitter anti-Catholic charges of the times. In general, they existed only two or three years, with the notable exception of the *Truth*

Teller of New York, begun in 1825 and closing an eventful career in 1855. The *Shamrock* struggled for 14 years, but with a suspension nearly every other year.

With the appearance of actual Catholic journals, the *Miscellany* in its prospectus gave these assurances: "The principles of the publication will be candor, moderation, fidelity, charity and diligence." Bishop England assembled agents for the paper in 31 cities of the young country. It was because of careful planning that the *Miscellany* continued until the 1860's. Second of the journals with episcopal approbation was the *Catholic Press*, which was begun at Hartford in 1829 by Bishop Benedict J. Fenwick of Boston and which lasted four years. The oldest American Catholic newspaper began as the *Catholic Telegraph* of Cincinnati, launched in 1831 by Bishop Edward D. Fenwick, apostle of Ohio. It survived the Civil War by following a wise and loyal course; was once edited by Sylvester H. Rosecrans, convert, brother of the Civil War general, and later bishop of Columbus; was at one time rescued by leading Catholic laymen, headed by Dr. Thomas P. Hart, later its editor and one of the best-loved figures in the field; and continues vigorously (1948) as the *Catholic Telegraph-Register*. The Boston *Pilot*, the other surviving formative period journal, was founded in 1836; was at times edited by the meteoric Thomas D'Arcy McGee, the celebrated John Boyle O'Reilly, and James Jeffrey Roche; was conducted skillfully throughout the Civil War by Patrick Donahoe; was wiped out three times in six months by fire in the 1870's, but occupies a prominent place in the 20th century. The *Pilot's* predecessor was *The Jesuit or Catholic Sentinel*, begun in 1829 by Bishop Benedict J. Fenwick in the face of puritanical survivals of prejudice, battling through the great convulsion of the burning of the Charlestown Ursuline convent in 1834, and surviving for six years. *Der Wahrheitsfreund* (*Friend of Truth*), outstanding German Catholic newspaper established in Cincinnati in 1837 by John Martin Henni, afterward archbishop of Milwaukee, continued until 1910, and was the great defender of the faith among newly arrived German immigrants. *The Catholic Herald*, launched in Philadelphia in 1833, with John Hughes, later archbishop of New York, as its first editor, continued for 33 years, and fought through the fire, bloodshed, and death of the anti-Catholic Nativist riots in the City of Brotherly Love in 1844. *The Catholic Advocate*, founded at Bardstown in 1836 but later moved to Louisville, continued until 1850. *The Official Catholic Directory*, later published by P. J. Kenedy & Sons of New York was established in 1822; it has been published annually since 1833.

Magazines in this period were notably few and short-lived. They numbered only five. Two juvenile publications were essayed, but failed. Seven bishops (or future bishops) were founders, sponsors or editors of journals of this period. Publications so begun had by far the greatest enduring qualities: one was hale in 1948; one persisted into the 20th century; two lasted until the Civil War. There is a record of 10 other priests who were founders or original editors.

Second Period (1840-1884).—For the nation, this was a confused era of growth and strife. For the Catholic Church, it was a continuance

of difficult but steady increase and expansion. For the Catholic press, it began with intensification of controversy, but this gradually waned and a general broadening began. Up to 1840 attacks on the church had been mostly verbal. Now there was resort to action, with appalling burnings and bloody riots. But these very excesses seemed to have a sobering effect on the anti-Catholic spirit. Non-Catholics gradually began to form more moderate judgments. Undoubtedly the arduous and persistent journalistic labors in the days before had done much to bring this about. With roots already planted, the Catholic press started to penetrate new territory and to expand as to content. Non-English speaking immigrants necessitated foreign language journals, and these were founded in considerable numbers. From 1840 to the beginning of the Civil War, foundations of Catholic publications more than doubled their yearly rate. Two newspapers survived in 1948 from those two decades. Virtually no foundations were made during the Civil War, but in the 19 years from 1865 to 1884, there was a host of them. We have definite record of 124, and of these, 31 were still in existence in 1948. We know of 171 Catholic publications started in the entire second period, of which 33 continue—20 newspapers, 13 magazines. The rate of survival had quadrupled.

Geographical expansion was vigorous. The Catholic press was extended to San Francisco and Portland on the west coast, and to New Orleans, Augusta, Memphis and Richmond in the South, establishing itself in most of the cities growing up around the Great Lakes, and penetrating energetically into the Midwest. A count of cities adds more than 50 to the 14 represented in the formative period. The first English language Catholic daily appeared in this period, although only briefly, when Peter McCorry launched the *Daily Telegraph* in New York in 1875. Catholic dailies twice were attempted in the German language field, but failed. Magazine attempts, sterile in the first period, began to bear fruit. Systems or chains of papers appeared. There was a notable multiplication of German language publications: in the 14 years between 1870 and 1884, no fewer than 20 are known to have started, and six survived in 1948. Several Polish publications were established, one of which continues (1948). One Spanish and one Bohemian paper likewise are survivors. French, Portuguese, and Dutch Catholic papers also were founded.

The colorful and important *Freeman's Journal* of New York, established in 1840, persisted until 1918, at times with heroism. Among its celebrated editors were James Roosevelt Bayley, afterward archbishop of Baltimore; the skillful, brave, but sometimes eccentric, convert, James A. McMaster, who brought the *Freeman's Journal* to national prominence in his 38-year tenure; and the brilliant Maurice Francis Egan. The *Pittsburgh Catholic*, begun in 1844 by Bishop Michael O'Connor, was still vigorously edited in 1948. *The Mirror* (Baltimore), was started in 1849 and continued until 1908. Two St. Louis papers, the *Western Watchman* (1865) and *Church Progress* (1878) persevered until 1933 and 1926. The famed poet-priest, Abram Ryan, edited the *Banner of the South* at Augusta, Ga., before the Civil War, and also *The Morning Star*, founded in New Orleans, La., in 1867 and published until after 1920. *The Tablet*, New York, continued

from before the Civil War to 1890 and had Orestes A. Brownson as an editor.

The west coast emerged: *The Monitor*, San Francisco (1858), remains (1948) in lusty health; the *Catholic Sentinel*, Portland, Oreg., (1870) likewise continues. A notable founding was that of *The Catholic Citizen* (later the vigorous *Catholic Herald-Citizen*) of Milwaukee (1870), which mothered the first system or chain of Catholic papers in the country, evolving a group in cities as widely separated as Minneapolis, Memphis and Washington, D. C. In 1874 there was established the *Catholic Universe* of Cleveland (afterward the strong *Catholic Universe Bulletin*), which likewise produced a chain of several papers under the parent company of the Catholic Press Union. Among other prominent survivors of the period are: *The Standard* of Philadelphia (1866), subsequently the influential *Catholic Standard and Times*; *Catholic Union* (later *Union and Echo*), Buffalo, (1872); *The Providence Visitor*, Providence, (1873); *The Catholic Transcript*, Hartford, (1876); *The Record*, Louisville, (1879); *The Catholic Messenger*, Davenport, (1882), and *The Michigan Catholic*, Detroit, (1883). Foreign language survivors include *Der Wanderer*, St. Paul, (1867); *Hlas* (Bohemian), St. Louis, (1871); *Revista Católica*, El Paso, (1875), and *Polish Nation*, Chicago, (1876).

Magazine efforts have left as survivors some of the most telling and scholarly periodicals of our time, including the excellent *Catholic World* of New York (1865), leading literary publication, established by Isaac Hecker, founder of the Paulists, and press apostle; *Ave Maria* (1865), launched by Edward Sorin, C.S.C. of Notre Dame, Ind., and the Jesuit *Messenger of the Sacred Heart*, New York (1866).

Third Period (1885-1919).—The Catholic press now began organizing for the solution of problems, made appraisals, and girded itself for what was to be a strong and concerted surge forward. The newspapers continued expansion, but with increasing caution. The magazines actively extended their numbers and importance. Once again there was a determined anti-Catholic disturbance—the vicious American Patriotic Association (A.P.A.) onslaught in the 1890's. Catholic editors rose once again to effective battle. In the new century, however, attention was more and more centered on news coverage, literary development, and sounder foundations.

There began in this period an insistent self-criticism which has since been typical of the Catholic press, and has brought distinct benefits. This healthy attitude led to efforts to form groups for mutual help. An association was attempted following the Catholic Lay Congress of 1889, but with indifferent success; a Catholic editors' convention was held in Chicago in 1893; and in 1905 a Catholic Associated Press was essayed but failed. In 1911, at Columbus, there finally was founded the Catholic Press Association of the United States and Canada, a significant development in the history of this press. The C.P.A. took as its first activity the organization of a news agency. While, for lack of resources, this did not develop in nine years beyond a "letter" service from three world capitals, and brief weekly cable dispatches from Rome, it did constitute a beginning and was the precursor of the widespread National Catholic Welfare Conference (N.C.W.C.) News Service. The associ-

ation has done other constructive things to advance the Catholic press. It developed a Circulation Vigilance Committee which did effective work in keeping dishonest solicitors from the magazine field. Under Simon Baldus of *Extension Magazine* (one of the leading editors of the time and afterward president of the C.P.A.), the association created a Literary Awards Foundation, the financial prizes of which were to encourage the development of Catholic writers. It provides a liaison between Catholic publications and their news service; conducts the *Catholic Journalist* in the interest of the Catholic press; and its conventions and sectional meetings make possible the interchange of ideas.

For the entire period of 34 years the total of newspapers surviving was 57, as against 20 for the previous period of 44 years. Nicholas Gonner in 1899 established *The Catholic Tribune* of Dubuque, which in 1920 produced the "first and only English Catholic daily in America" with any endurance. The paper eventually became the *Catholic Daily Tribune*, which survived until 1942. The Catholic Press Union of Cleveland in this period undertook the publication of papers for other dioceses. There also were established the *Catholic Register* of Denver, (1910) and *Our Sunday Visitor* of Huntington, Ind., (1912), which were to create impressive chains of papers in a later period. *Our Sunday Visitor* was launched by John F. Noll (later bishop of Fort Wayne, Ind.) to counteract directly the influence of such rabidly anti-Catholic weeklies as *The Menace*. It attained an impressive national circulation and retains (1948) a commanding position. A few of the other newspapers established in this period (some of which are leaders of the Catholic press) are: *The Catholic News*, New York, founded in 1886 by Hermann Ridder and once edited by the celebrated historian John Gilmary Shea; *The New World*, Chicago, (1892), with Charles J. O'Malley once its editor; *The Tidings*, Los Angeles, (1895); *The Catholic Northwest Progress*, Seattle, (1898); *The Tablet*, Brooklyn, (1908); and *The Catholic Review*, Baltimore, (1913).

The Society of Jesus established in New York in 1909, *America*, the first weekly Catholic publication of opinion in the country. It was edited by John J. Wynne, S. J., and developed an international prestige. The important *Young Catholic Messenger* began at Dayton in 1886, and issues several highly successful journals for school children. Magazines founded in this period and still published (1948) reach the impressive number of 99.

Modern Period (1920—).—In World War I, the bishops promptly created the National Catholic War Council, which earned high admiration for its great service to morals and morale in the war. At the conclusion of the war, the bishops immediately revised this organization for peacetime efforts. The National Catholic Welfare Conference, which they then organized as their central episcopal agency, had an epochal effect on all American Catholic activity. An able and distinguished journalist, Justin McGrath, was obtained as director of the N.C.W.C. Press Department. He organized it and conducted it energetically until his death in 1931. At once a program was drawn up which envisioned for Catholic journals services of news, features, and pictures such as had long been available to the general press of America. The C.P.A. readily turned

over its own abbreviated news service. The department under McGrath and his successor, up to the year 1948 developed the following facilities: (1) A news service of approximately 50,000 words a week, reporting promptly from all parts of the world news of interest to Catholics as Catholics; (2) a Catholic feature service of about 10,000 words a week, designed to interest all members of the Catholic family; (3) a Catholic news picture service providing illustrations for current Catholic news; (4) a telegraphic service to flash last-minute news to subscribers; (5) an editorial information service supplying factual material for editorial writers; (6) a biographical service presenting life sketches of prominent Catholic figures; (7) a Washington letter, interpreting national events of particular interest to Catholics; (8) special texts of important Vatican documents, radioed immediately upon their issuance; (9) special syndications of articles on subjects of high timeliness and interest; and (10) special supplements—budgets of features, fiction, poetry, and pictures to assist publications with special editions at appropriate seasons. There also had been created an Overseas Service for publications abroad.

While the N.C.W.C. News Service was originated to strengthen the American Catholic press, in 1948 it had subscribing publications in 43 countries. In the early 1940's it began issuing *Noticias Católicas*, an adaptation of its news in Spanish and Portuguese, for Latin American publications. The news service speedily was accorded recognition. Members of its staff are accredited in the press galleries of Congress and in the White House press conferences, two groups zealously limited to professional journalists. Many of its reporters were accredited officially as war correspondents in World War II. Newspapermen of thorough experience constitute the headquarters staff and correspondents in world capitals and in the United States. The service has registered notable news beats. In World War II it obtained exclusively the textual documents of the German, French, Austrian, Dutch, and Belgian hierarchies resisting the Nazis. This material was used by the United States government and eventually printed in book form.

A strong and steady increase of papers succeeded the launching of the N.C.W.C. News Service. The stream of new enterprises cannot be enumerated here, but in 1948 there were 95 diocesan organs.

The Catholic newspaper experienced many sharp changes. Its world and national news content was multiplied; varied features were added; the use of pictures increased rapidly; and comic strips and cartoons lent variety. The paper became more informative and gave its readers more general fare. It came to depend less on the personality of its editor. When the next recrudescence of anti-Catholicism appeared with the Ku Klux Klan in the 1920's, the Catholic press took the visitation in its stride; there was effective editorial resistance, but the papers continued to fulfill their main mission of providing news, instruction, inspiration, and entertainment. Trained lay journalists began coming into the field in increasing numbers as managing editors. General, business, advertising, and circulation managers were added in many instances. This made for more professional management and thus financial soundness. Magazines soared in number and circulation. Between 1920 and 1945, there were

founded 110 that were still being published in the latter year. Preponderantly, the newspapers are weeklies; the magazines, monthlies. Circulations of individual newspapers in 1945 had advanced beyond the 100,000 mark, and many had 40,000 to 80,000 subscribers. The circulation of one Catholic magazine was approaching a million; other magazines were near the half-million mark and many were beyond 100,000.

Important new newspaper chains developed. The pioneer *Citizen* group was disbanded in 1934, but the Catholic Press Union was publishing three individualized diocesan organs with a circulation of approximately 100,000. In 1929, the Catholic Publishing Society of Denver, already issuing the *Denver Catholic Register* and the successful national *Register*, began a system of supplying official organs for other dioceses, that in 1948 spread to 32 sees, including such centers as Cincinnati, St. Louis, and Santa Fe, and extending from California to Pennsylvania, and from Tennessee to Montana. The driving force in this campaign was a newspaperman who had entered the priesthood—Msgr. Matthew Smith. He built a great publishing plant and even created his own school to train those who would be editors of his far-flung journalistic endeavors. In 1947 the group reported a circulation of near 650,000. The second most widespread system was that of *Our Sunday Visitor* Press. After making a striking success of its national weekly (chiefly of apologetical and instructional character), setting up a large pamphlet-issuing agency, and beginning the publication of a home (Fort Wayne diocese) newspaper, in 1940, *Our Sunday Visitor* went into individual territories and shortly had extended to its tenth diocese. This agency in 1947 reported a circulation of 664,429, for its national weekly and its diocesan editions. *Catholic Action of the South*, New Orleans (established in 1932) began founding editions for three neighboring dioceses in 1938.

The Bulletin, Augusta, (1920) brought a new note. Controlled by the Catholic Laymen's Association of Georgia, it developed, in a wave of anti-Catholic bigotry, its own technique of applying patient, corrective truth. Its remarkable service continues (1948).

Foreign language publications were established despite the difficulties of the times. In 1947, there were two Polish dailies, one Bohemian, and one Lithuanian. Of all foreign language Catholic periodicals, there were 17 Polish, 12 Bohemian, 9 French, 9 German, 5 Slovak, 4 Spanish, 4 Lithuanian, 3 Italian, 3 Croatian, 3 Slovenian, 2 Hungarian, 2 Ruthenian, 2 Ukrainian, and 1 Russian.

Following are some of the remarkably varied fields encompassed by Catholic magazines in 1948: antiprofanity, arts and crafts, Biblical studies, the blind, catechists, Catholic action, chaplains, charities, church goods, church music, church property, clergy, converts, the deaf, deaf mutes, ecclesiastical law, education, family, farm life, fraternal organizations (men and women), girls, history, Holy Land, Indians, interracial justice, journalists, libraries, liturgical arts, missions (foreign, home, medical), Negroes, opinion, parish life, peace, philosophy, physicians, poetry, religious instruction, school children, school editors, shrines, social justice, sodalities, stagecraft, temperance, theater, theological studies, war veterans, women, and workers.

A few of the magazines existent in 1947

were:

The Messenger of the Sacred Heart, New York (1866), circulation 301,144; *Annals of the Holy Childhood*, Pittsburgh (1870), 266,000; *Crusader's Almanac*, Washington, D.C. (1886), 262,000; *Orphan's Messenger and Advocate of the Blind*, Jersey City, N. J. (1890), 120,000; *The Catholic Forester*, Chicago (1892), 133,000; *Columbia*, New Haven (1893), 650,000; *St. Anthony Messenger*, Cincinnati (1893), 310,000; *The Victorian*, Lackawanna, N. Y. (1894), 167,700; *Extension Magazine*, Chicago (1905), 486,000; *Field Afar*, Maryknoll, N. Y. (1906), 420,000; *Catholic Missions*, New York (1907), 800,000; *Far East*, St. Columbans, Nebr. (1918), 162,893; *The Sign*, Union City, N. J. (1921), 181,000; *The Vincentian*, St. Louis (1923), 160,000; *Jesuit Missions*, New York (1927), 125,000; *The Catholic War Veteran*, New York (1935), 150,000; *The Catholic Digest*, St. Paul, Minn. (1936), 275,000; *Leaves*, Detroit (1938), 125,000; *The Fraternal Leader*, Batavia, N. Y., 100,000. *The Young Catholic Messenger*, leading juvenile, had an impressive 426,177.

Professional journals in particular fields were established chiefly since 1910. These include:

Ecclesiastical Review (1889), *Catholic Educational Review* (1911), *Catholic Historical Review* (1915), *Catholic Charities Review* (1917), *Directory of Catholic Colleges and Schools* (1921), *Catholic Biblical Quarterly* (1939), all of Washington, D.C., and several fostered by the Catholic University of America; *Homiletic and Pastoral Review*, New York (1900); *Hospital Progress*, St. Louis (1920); *Catholic Library World*, Scranton, Pa. (1929); *The Linacre Quarterly* (for physicians), St. Louis (1932); *The Priest*, Huntington, Ind. (1945). Published studies and records of Catholic historical groups have done much to preserve Catholic history. *The Communal* (1924), only American Catholic weekly of opinion by laymen; *The Interracial Review* (1928), and *The Catholic Worker* (1933), are published in New York. *Catholic Action*, Washington, D.C. (1919), N.C.W.C. organ, deals largely with the general activities of the hierarchy. *The Catholic Digest*, St. Paul (1936), is of comparatively new type and is published also in other countries in various languages, as well as in braille. *Timeless Topics*, St. Paul (1942), is a counter-publication to the comic-strip book, with a circulation of 300,000.

For journalistic education under Catholic auspices, five Catholic universities and colleges offer professional courses, and 50 others give cultural or supplementary instruction in the field.

Besides those mentioned, other agencies and organizations lending aid to the Catholic press include: the Catholic School Press Association, issuing *The Catholic School Editor*; the Catholic Poetry Society of America, with its own journal; the Gallery of Living Catholic Authors, providing a reward for those Catholics attaining prominence in letters; the annual *Catholic Press Directory* and the semiannual *Catholic Periodical Index*, both issued in New York. February is the annual Catholic Press Month, set aside to advance interest in and reading of Catholic publications.

FRANK A. HALL,

Director, National Catholic Welfare Conference News Service.

CATHOLIC EMANCIPATION ACT, adopted by the British Parliament in 1829, removed such "qualifications for sitting and voting in parliament" as had prevented Catholics from enjoying political equality in that respect with other subjects of the crown. In 1828, the nom-

inal exclusion of Protestant dissenters and the actual exclusion of Catholics from offices under the crown and in local government had been voided by the repeal of the Test and Corporation acts. The prime minister, the duke of Wellington, then recommended the act of 1829 for passage in order to meet the demands of Catholics. He so moved under threat of a revolution in Ireland, where the peasantry had shown their independence by electing Daniel O'Connell to Parliament in 1828, despite the fact that he was, as a Roman Catholic, not entitled to serve. Although full religious equality was not established (for example, Catholic marriages were still illegal, and Catholics in the army and navy were still required to attend Protestant services), the act of 1829 was a true emancipation in that it opened places to Catholics in the sovereign legislature. All that was required was that they take an oath disclaiming any opinion that "princes excommunicated by the see of Rome may be deposed or murdered by their subjects or by any person whatsoever."

Numerous measures looking to political equality had been taken earlier. In the middle of the 18th century, it could still be said that "the law does not suppose any such person to exist as an Irish Roman Catholic except for repression and punishment," despite the fact that Catholics constituted four fifths of all Irishmen; English Catholics were a tiny minority liable to forfeiture of property or, in the case of their clergy, subject to imprisonment for life, depending upon the whim of some informer who might choose to invoke the laws against the administration of the sacraments; and the Scottish Highlanders were undergoing, as Catholics and rebels, further persecution for their participation in the Stuart uprising of 1745. But even then there had begun a gradual modification of law and practice by which the Parliament in Westminster, and the Irish Parliament in Dublin, as well as judges and administrators in both kingdoms, introduced successive modifications of repressive practices.

In 1774, the British government had found it necessary to accord recognition to the Catholic Church in Canada, where the French inhabitants constituted a major portion of the population. In the same year the Irish Parliament admitted that Irish Catholics could be loyal subjects of the crown when a new oath of allegiance was provided for them. The same law permitted Catholics, for the first time since the reign of Queen Anne, to acquire and transfer titles to land, and it abolished the right of an heir who turned Protestant to take over the whole of an estate so as to exclude Catholic sons and reduce the father's interest to that of a mere life tenant.

Other disabilities and incapacities were removed then and subsequently, up to 1793, such as the exclusion of Irish Catholics from the professions and from any profitable business. The right to vote was conceded in 1793—even to the peasantry who qualified as "forty-shilling freeholders."

Among the influential advocates of the rights of Catholics was that friend of America, Edmund Burke, whose mother had been Catholic. Burke voiced opinions which were in harmony with the aims of the Whig opposition to George III's government. The Whigs, constituting a strong economic influence in both kingdoms, included a powerful body of absentee landlords who hoped to increase their influence in the Irish Parliament

as against the crown influence. It was also characteristic Whig doctrine to espouse broad principles of religious toleration, to assuage religious passions in the interest of economic progress. On the other hand, the administrators of the crown interest in Ireland found it increasingly difficult to avert legislative crises without resort to more and more corruption in Parliament, which after 1782 could proceed with any measure without the prior approval of the Privy Council in England. If the further extension of rights to Catholics were to include full participation in political activity, the government's task would become impossible. Hence the clique of officeholders associated in name with Dublin Castle, having reluctantly agreed to the removal of most of the remaining social inequalities for Catholics in 1793, continued stubbornly to oppose the movement for granting full political rights.

The crisis came in 1794, when the Whig Earl Fitzwilliam (William Wentworth Fitzwilliam, 2d earl) became lord lieutenant. He sought to introduce Whig officeholders and grant Catholics the right to sit in Parliament, thus attaching them to the Whig interest. The Castle clique appealed desperately to their friends in England to do something. The king was reminded of his coronation oath—which he thought he would violate if he gave his assent to the proposed emancipation of Irish Catholics—and the Fitzwilliam administration was ruined. Revolution broke out in 1798, but was crushed by a Protestant militia which the Castle encouraged to many excesses. Nevertheless, the British government's desire to eliminate the separate legislature in Ireland induced it to make a pledge of emancipation to the Catholics, to follow Irish consent to a union of parliaments; and this was one of the numerous bargains by which there was arranged, in 1800, the extinction of the Parliament in Dublin. But George III refused to ratify any arrangements with the Catholics. He drove the responsible prime minister, William Pitt, from office, and after several years of conflict with the Whigs, who tried to force him to honor the pledge made in his name, the king emerged triumphant in 1809 with a ministry dedicated to the upholding of the Protestant ascendancy in both countries.

Repression in Ireland, and the antiliberalism promoted by opposition to the French Revolution during the Napoleonic Wars which lasted until 1815, made the prospect of Catholic emancipation as unlikely as any of the reforms which had been urged before 1793. Nevertheless, as successive reconstitutions of the English government took place after 1812, places among the ministers came to be filled by those who were known to favor what George III had sternly forbidden before he became insane in 1810 and was confined. His successor, first as prince regent and then (1820-1830) as George IV, was in harmony on this point with his most reactionary advisers. Catholics in England split with those in Ireland on the question of the exact form in which they might be "embraced within the constitution" (the matter of governmental controls over episcopal appointments caused particular trouble), and this made the rejection of various bills easier whenever some private member introduced them in Parliament. But agitation in Ireland, which by the 1820's was in a ruinous economic condition, forced action upon an unwilling Tory government. The brilliant leadership of O'Connell, who had the support of the Catholic clergy, produced the

first democratic pressure group in the form of the Catholic Association. When a disciplined peasantry showed that it could, when called upon, defy the landlords who were supposed to control their votes, and even gave these votes to O'Connell, and when attempts to outlaw the association only caused its revival under a different guise, it was recognized in England that political control of Ireland would soon be impossible. At length, and with bad grace, the duke of Wellington was persuaded to make concessions in the manner of a general executing strategic withdrawals. The act received the royal assent April 13, 1829, having passed through Commons and Lords by large majorities; but the spirit in which these majorities acted was revealed by the simultaneous passage of a bill to disenfranchise the forty-shilling freeholders in Ireland, and by the refusal to admit O'Connell to the House of Commons until he was re-elected.

JOHN T. FARRELL,
The Catholic University of America.

CATHOLIC EPISTLES, a group of seven letters in the New Testament which are addressed by apostles to the faithful in general; not to particular churches, as is that to the Philippians, that to the Ephesians, and the like, nor to individuals, as are the Epistles of Paul to Timothy and Titus. The catholic or general Epistles are those of James; I and II Peter; I, II, and III John; and the Epistle of Jude. These same Epistles are also styled canonical, signifying that they contain excellent rules (*canones*) of faith and morals.

CATHOLIC KNIGHTS OF AMERICA, a fraternal organization, founded in Nashville, Tenn., in 1877 and chartered under the laws of Kentucky in 1880. Its object primarily was mutual life insurance, but its scope was eventually extended to include the endeavor to unite fraternally all acceptable Roman Catholics of every profession, business, and occupation; to give all possible moral and material aid in its power to members of the organization; and to establish and maintain a fund for the benefit of the families of the members. The benefit fund is distributed according to well-established insurance rules. At first men only could become members; but since about 1901, women have been allowed admission on the same conditions as men, except the age limits for women are from 18 to 40, while the age limits for men are from 18 to 45. The executive power is vested in the Supreme Council (National) with headquarters in St. Louis, Mo., the state councils, and the officers of the local branches. In 1953 there were 259 branches in 32 states of the United States, with a membership of 13,018. This is the pioneer Roman Catholic fraternal organization in the United States.

CATHOLIC LIBRARY ASSOCIATION, an organization of about 2,000 librarians and other bookmen interested in the growth of Catholic libraries and librarianship. It includes members from the 48 states, the United States possessions, and 11 foreign countries. Headquarters, which

move with the change of the executive secretary, in 1954 were located at Maryknoll Seminary, Glen Ellyn, Illinois.

The idea of an organization of Catholic librarians was first conceived in 1921, when the Reverend Paul J. Folk, C.S.C., introduced a library section into the National Catholic Educational Association. This group met in annual convention with the parent organization for the next decade, until in 1931 it became independent under the leadership and first presidency of the Reverend William S. Stinson, S.J.

The growth of Catholic educational institutions in America, especially on the secondary and college levels, made it imperative that the new association move quickly to encourage and direct the training of librarians, to stimulate the intelligent planning of library buildings, and to promote the introduction of library science departments in Catholic institutions of higher learning. Though meager financial resources seemed to forebode failure such pretentious aims, the enthusiastic interest of the membership on an individual basis brought exceptional results. This is witnessed by the thousands of professionally trained librarians now supervising Catholic libraries, the multimillion-dollar library building programs in Catholic institutions, and the 25 Catholic colleges offering courses in library science.

The association, while organized on a national scale, is able to operate on the modest income of \$50,000 a year derived for the most part from dues and subscriptions—chiefly because of the contributed services of the membership. The organization is governed by an executive council of ten members chosen by general vote. As of 1954 there had been 30 national conventions of the association. Twenty-nine local units bring the benefits of the larger group to as many sections of the country through regional meetings, book fairs, and other bibliographical activities.

All types of libraries are represented in the association: public, university, college, secondary and elementary school, parish and hospital. Neither the libraries nor their librarians look to the association as a substitute for other library groups, such as the American Library Association, but as complementary to them, since it provides certain specialized services not available elsewhere.

Under the association's auspices have been published selected book lists of special interest to Catholic readers, both as independent works and as supplements to basic bibliographical tools; an *Alternative Classification for Catholic Books* and the *List of Catholic Subject Headings* have greatly aided librarians in both secular and religious libraries in the cataloging of the voluminous, technical Catholic literature. Another contribution is the *Catholic Periodical Index*. Begun in 1930, this quarterly index to over a hundred Catholic periodicals in all languages is the only religious index of its kind. The *Catholic Library World* published monthly and now in its 25th volume is the organization's official organ containing news of the field, proceedings of the national and local meetings, articles and book reviews bearing on the technical aspects of Catholic librarianship. An annual directory of the personal and institutional members of the association is issued as a supplement to the magazine.

Catholic Book Week, observed annually the last full week in February, provides the association with its most extensive contact with the public by means of posters and book lists aimed at stimulating good reading. See also **LIBRARIES—United States.**

VINCENT T. MALLON, M.M.,
Executive Secretary.

CATHOLIC MAJESTY, a title given by Pope Alexander VI to the kings of Spain, in memory of the complete expulsion of the Moors from Spain in 1491 by Ferdinand of Aragon. But even before that time several Spanish kings are said to have borne this title.

CATHOLIC MISSIONARY UNION, The, an organization of the Roman Catholic Church, was established to maintain and promote the missionary apostolate in the United States. Publishing, distribution of literature, and the training of missionaries for the mission field have been the chief activities of the organization. Formerly occupying the Apostolic Mission House on the campus of the Catholic University of America, the union has moved its quarters to St. Paul's College, the Paulist seminary in Washington, D.C., where lectures are held and courses in missiology for priests and seminarians are conducted. As a practical measure for accomplishing its purpose, the Catholic Missionary Union has placed special emphasis on the collection of funds. Financial assistance is given the bishops and superiors of religious communities in whose jurisdictions the mission work is carried on. The larger portion of these collections goes toward the support of missionaries working among the Negroes and Indians and to the support of activities in the poorer sections of the United States.

Organized by the Paulist Fathers, the union is controlled and operates through a board of directors whose president is always the archbishop of New York City. The distribution of funds is left entirely to the discretion of the board of directors.

CATHOLIC MISSIONS. See **MISSIONS, ROMAN CATHOLIC.**

CATHOLIC PARTIES, political parties in many continental European countries organized to defend the principles of Roman Catholicism in governments increasingly dominated by Socialist and other anti-Catholic forces. While having no official connection with the church, they have always enjoyed its support. The party in Germany, called the Center Party (*Zentrums-partei*), evolved from groups in the 1848 Frankfurt National Assembly and the Prussian Landtag of 1852 and held seats in Parliament from 1859. It waged the *Kulturkampf* (q.v.) contest with Bismarck; supported the Weimar Republic, and was suppressed by Hitler. In France no Catholic party existed during the Third Republic (1870–1940); but the Mouvement Républicain Populaire (MRP), organized in 1944, represents Catholic principles. Italy's Catholic Party (1905), renamed Italian Popular Party in 1919, was suppressed by Mussolini; after World War II it was reconstituted as the Christian Democratic Party. Catholic parties also exist in Belgium, The Netherlands and Switzerland; prior to Communist seizures, Czechoslovakia and Poland likewise had Catholic parties.

Since 1936 the National Union Party, a Catholic party, has dominated the Province of Quebec, save for an interval of less than five years (1939–1944) under Liberal Party control.

CATHOLIC UNIVERSITY OF AMERICA, an institution for higher education maintained by the Roman Catholic Church in the United States, at Washington, D.C. The need for a university in which instruction should be given and research conducted in all the departments of knowledge, under Catholic auspices, was recognized by the bishops assemblies in the Second Plenary Council of Baltimore (1866); and the establishment of such an institution was resolved upon in the Third Plenary Council (1884). Pope Leo XIII in 1887 approved the project, and granted the pontifical charter by the Apostolic Letter *Magni nobis gaudii* of March 7, 1889. The university was incorporated under the laws of the District of Columbia, and the city of Washington was selected as the site. The Right Reverend John J. Keane, then bishop of Richmond, Va., was designated rector of the university. In November 1889, academic work was inaugurated in the school of the sacred sciences. The schools of philosophy and social science were opened in 1895. There have been several reorganizations of the university with steady expansion of activities until the present scheme was established in 1937. The university now consists of the school of sacred theology, school of canon law, school of philosophy, school of law, college of arts and sciences, graduate school of arts and sciences, school of engineering and architecture, national Catholic school of social service, school of nursing education, school of social science, and summer sessions.

The "organic law" of the university is embodied in the statutes which were approved by the Holy See in 1937. It provides that the bishops of the United States shall have plenary authority in all matters pertaining to organization, instruction, or discipline. This authority is exercised by a board of trustees composed of bishops, priests, and laymen, who may elect new members and fill vacancies in the board. The chancellor, as the representative of the Holy See, presides at the meetings of the trustees. Subject to the authority of the trustees, the immediate government of the university is placed in the hands of the rector, assisted by the academic senate. The ex officio members of the senate are the rector, the vice rector, the secretary general, and deans of the faculties. In addition, each faculty elects one delegate to serve in the senate for two years.

The senate acting with the rector has competency in matters pertaining to the methods of instruction, the appointment of associate professors, and examinations for degrees. It proposes to the board of trustees such measures as may seem advantageous for the development of the university, and it recommends to the chancellor successful candidates for degrees.

The work of each school is in charge of a faculty composed of professors appointed by the board of trustees. The school comprises various departments in which courses are given by professors, associate professors, assistant professors, instructors, and occasional lecturers. The faculty makes recommendations to the rector who appoints officers—dean, vice dean, and secretary—and one delegate to the senate. It has a consultative voice in regard to the appointment or re-

moval of professors and, subject to the decision of the senate, draws up or revises courses of study, examines candidates for degrees, and makes recommendations for the development of the school.

University revenues are derived from endowments, donations for special purposes, tuition fees, and annual collections taken up in each diocese of the United States. A detailed statement of the receipts and expenditures is published yearly. There are 25 endowed chairs, 12 fellowships (nine founded by the Knights of Columbus, 1914), 216 graduate scholarships, and more than 100 undergraduate scholarships. The student body includes clerics and laymen, the former representing the diocesan clergy and religious orders.

The courses offered in the various schools of the university are for graduates only, the exceptions being in the school of philosophy, the school of engineering and architecture, the school of nursing, and in the college of arts and sciences. The college of arts and sciences is devoted entirely to undergraduate work, and the other schools just mentioned give courses for undergraduates and graduates. To be permitted to enter upon undergraduate work, a student must present the credentials regularly required by colleges and universities approved by the Middle States Association of Colleges and Secondary Schools.

Grouped about the university are the houses of study of many religious communities, notably:

Atonement Seminary, Augustinian College, Basselin Foundation, Benedictine Sisters, Capuchin College, Carroll House, Catholic Sisters College, Clarean Fathers, De La Salle College, Discalced Carmelite Fathers, Dominican House of Studies, Fathers of Mercy, Franciscan Friary, Franciscan Sisters of Christian Charity, Holy Cross College, Holy Family Seminary, Holy Ghost Fathers, Holy Name College, Holy Redeemer College, Holy Trinity Missionary Cenacle, Marian House of Studies, Brothers of Mary, Marist College, Oblates of Mary Immaculate, Oblates of St. Francis de Sales, Pallottine House of Studies, Queen of Apostles Seminary, Resurrection Scholasticate, Sacred Hearts Seminary, St. Anselm's Priory, St. Bonaventure Friary, St. Charles House of Studies, St. Gertrude's School of Arts and Crafts, St. Jerome's House of Studies, St. Joseph's Ukrainian Catholic Seminary, St. Joseph's Seminary, St. Paul's College, School Sisters of Notre Dame, Sisters of St. Joseph, Society of Medical Missionaries, Society of the Divine Word, St. Thomas More House of Studies, Third Order Regular of St. Francis, Trinity College, Viatorian Seminary, Vincentian Fathers, White Fathers of Africa, Whitefriars Hall (Carmelite).

The houses of other communities having connection with the university are located in Washington proper, and in the neighboring communities of Hyattsville and Silver Spring.

The Catholic Sisters College, established in 1911, serves as a residence for members of religious communities of women enrolled for study at the university.

Since 1911 a summer session has been offered by the university at Washington, and branches of this session restricted to work for the master's degree and in four or five fields only, in other parts of the country as follows: at San Rafael, California, since 1932; at Dubuque, Iowa, since 1934; at San Antonio, Texas, since 1935; and at Chicago, Illinois, since 1946. The enrollment for 1953 was distributed thus: Washington 2,770; San Rafael 92; Dubuque 94; San Antonio 120; Chicago 84.

In 1912, the university adopted a plan for the affiliation of colleges and high schools. Since then, it has been extended to include junior colleges, teacher-training institutions, and nurs-

ing schools. The aim of this plan is to furnish guidance to those institutions, and to assist them in meeting their individual problems.

The official publishers of the university are the Catholic University of America Press. Periodicals issued by the university include: *The Catholic Educational Review*; *The Catholic Historical Review*; *The Corpus Scriptorum Christianorum Orientalium*; *Studies in Psychology and Psychiatry*; *The New Scholasticism*; *The American Ecclesiastical Review* . . . Monographs; *Proceedings of the American Philosophical Association*; *Primitive Man and Publications of the Catholic Anthropological Conference*; *The Educational Research Monographs*; and *The Catholic University Bulletin*.

The university student enrollment for 1953-1954 numbered 3,385. The teaching staff comprised 408, including 60 professors.

Roy J. DEFERRARI,
Secretary General, Catholic University.

CATHREIN, kä-trin', Victor, Swiss Jesuit writer and sociologist: b. Brig, Wallis Canton, Switzerland, May 8, 1845; d. Aachen, Germany, Oct. 9, 1931. Educated at the Brig gymnasium, and at various Jesuit scholasticates, Cathrein entered the Society of Jesus in 1863, and in 1867-1869 was professor of German at the Belgian colleges at Antwerp and Verviers. During the Franco-Prussian War of 1870-1871 he cared for wounded French soldiers at Koblenz, but in 1872 was expelled from Germany under the law banning the Jesuit Order. Ordained to the priesthood in 1877, he was a member of the editorial staff of *Stimmen aus Maria-Laach* for three years, and from 1882 to 1912 was professor of ethics at Jesuit houses in Holland.

A prolific writer, several of his scholarly books achieved popularity and were often reprinted. Representative works include *Die englische Verfassung* (1881); *Recht, Naturrecht und positives Recht* (1900; 22d ed., 1909); *Moralphilosophie*, 2 vols. (1891; 5th ed., 1911); *Die Aufgaben der Staatsgewalt und ihre Grenzen* (1882; 10th ed., 1915); *Die katholische Weltanschauung* (6th ed., 1921); *Die dritte Internationale* (1921); *Der Sozialismus* (1890; 14th ed., 1923); *Sozialismus und Katholizismus* (1929); *Lust und Freude, ihr Wesen und ihr sittlicher Charakter* (1931).

CATILINE, kät'i-lin (LUCIUS SERGIUS CATILINA), Roman politician: c. 108-62 B.C. To Cicero's four speeches against him (*Orationes in Catilinam*) and to Sallust's essay on his plot (*De Bello Catilinae*) we owe most of our knowledge of his celebrated conspiracy against the Roman Republic.

Catiline, scion of an impoverished patrician family, first appears as a supporter of Sulla (q.v.), from whose proscriptions (82-81 B.C.) he profited. After the quaestorship in 70 B.C. and the praetorship in 68 B.C. he governed Africa as propraetor in 67 B.C. and returned in 66 B.C. to Rome, where his candidacy for the consulship of 65 B.C. was thwarted by his trial for provincial extortion. By bribery he bought his acquittal in 64 B.C. in time to seek the consulship for 63 B.C. Defeated at the polls, Catiline announced his candidature for 62 B.C. It was this renewed attempt that inspired his plot to seize control of the state.

Meanwhile Catiline's debauchery, daring, and

largess had won for him the championship of the most abandoned and desperate elements in Italy: criminals, gamblers, rakehells, debt-ridden nobles and peasants, restless veterans, ne'er-dowells, prodigals, perverts, who had nothing to lose and everything to gain from his program of a "new deal," which included cancellation of debts and confiscation of political enemies' property. Even some senators and ex-magistrates supported him in hope of financial profit. But, since too many persons were privy to the plot to elect Catiline consul by hook or crook for it to be kept a secret, news of it soon reached Cicero (q.v.), who, the more patriotic of the two consuls in 63 B.C., determined to prevent Catiline's election. Cicero first gained the neutrality of his colleague Antony (uncle of the future triumvir), who was suspected of favoring Catiline, and then he paid Fulvia, a courtesan and the mistress of a Catilinarian, to keep him informed of the plotters' plans.

By September Cicero had sufficient information, though not proof, to expose Catiline's conspiracy in the Senate, where Catiline defiantly denied Cicero's charges. This exposure induced the chief conspirator to twofold action: to start a revolt at Fiesole, headed by his lieutenant Manlius, who had gathered a crew of desperados there and who was to march on Rome on October 27; and to seize Rome on the next day during the balloting for offices by firing parts of the city and by murdering senators and aristocrats. But Cicero convoked the Senate on October 21, declared the details of the conspiracy, and secured the passage of the *senatus consultum ultimum*, a senatorial resolution putting the state under martial law for the duration of an imminent danger. This disclosure also decided the poll (held on October 28), since, as reports of Catiline's recklessness spread, sober citizens rallied in a heated election to reject his bid for the consulship.

Manlius started operations on schedule, but tarried in Tuscany, where he waited for final word. Catiline, since his plot had been bared and he had been rebuffed at the polls, altered his plan and arranged to assassinate Cicero on November 7 and then to seize the city. Cicero heard of the change in time and convened the Senate on November 8, when he denounced Catiline (*First Catilinarian*). Catiline attempted to answer this speech, but the senators silenced him with shouts. Threatening and cursing, he rushed from the session and during the night fled to Fiesole. On November 9 Cicero addressed the populace (*Second Catilinarian*), to whom he explained what had happened and what measures he was taking for their safety. When it soon was reported in Rome that Catiline had assumed the consular insignia at the conspirators' camp, the Senate voted Catiline a public enemy.

The plotters who remained in Rome prepared to fire the city, to massacre as many patricians as possible, and then to join Catiline on his anticipated approach with Manlius' army. At last proof of this plot came into Cicero's hands on December 3, when, through informants, he was able to capture signed and sealed letters from the conspirators to Catiline and to the chief of the Allobroges, a Gallic tribe, whose support the Catilinarians had hoped to secure. Five of the principal plotters, arraigned before the Senate and confronted with the evidence, confessed their guilt. Then Cicero again spoke to the people

(*Third Catilinarian*) and showed them how the incriminating proof had been secured. On December 5 they were condemned to death by an overwhelming vote of the senators, though Caesar (sometimes suspected of having used Catiline as a cat's-paw) advocated perpetual imprisonment. On this occasion Cicero delivered the last of this series of orations (*Fourth Catilinarian*), in which he urged capital punishment for the conspirators. On that evening they were strangled in the civic jail under the supervision of Cicero, who assumed the responsibility for their execution without a trial and under martial law.

Antony then led an army against Catiline's forces in Tuscany, where on Jan. 5, 62 B.C. his lieutenant Petreius in a bitter battle at Pistoia defeated the rebels, who, inspired by their leader's example, died almost to a man and "all with wounds in front" (Sallust).

Sallust's characterization of Catiline is memorable: "He had great mental and physical vigor, but a character evil and depraved. From his youth he engaged in murder, rapine, political discord, civil war. His body could endure hunger, cold, sleeplessness beyond incredible limits. His mind was bold, cunning, treacherous, capable of pretense and of concealment. He was covetous of others' wealth, but prodigal of his own, fiery in passion, quite eloquent, but less discreet. His undisciplined spirit ever craved the monstrous, the incredible, the gigantic. And he was incited by the corruption of public morality, which was being destroyed by mutually opposed evils: extravagance and avarice."

P. R. COLEMAN-NORTON.

CATINAT, kâ-tê-nâ', Nicolas de, marshal of France: b. Paris, France, Sept. 1, 1637; d. St. Gratien, Feb. 25, 1712. He gave up the profession of law for that of arms, and attracted the notice of Louis XIV by his valor at the storming of Lille in 1667, which gained him promotion. By a number of splendid deeds he won the esteem and friendship of the great Condé (Louis II), particularly by his conduct at the Battle of Seniffe. Sent as lieutenant general against the duke of Savoy, he gained the battles of Staffarda, Aug. 18, 1690, and of Marsaglia, Oct. 4, 1693, occupied Savoy and part of Piedmont, and was made marshal in 1693. In the conquered countries his humanity and mildness often led him to spare the vanquished, contrary to the commands of the marquis de Louvois, minister of war. In Flanders he conquered Ath in 1697. In 1701 he received the command of the army in Italy against Prince Eugene, but here he was less successful. Destitute of money and provisions, and hampered by orders from court, he was defeated at Carpi on July 6, and at the Battle of Chiari on Sept. 1, 1701. In spite of the perfidy of the duke of Savoy, Catinat's representations at court were not believed and he fell into disgrace. From his unalterable calmness and consideration his soldiers called him "le Père la Pensée."

Consult his *Mémoires* (Paris 1819) and the biography by E. De Broglie (1902).

CATINEAU-LAROCHE, kâ-tê-ô' lâ-rôsh, Pierre-Marie-Sebastien, French politician: b. St. Brieu, Brittany, France, March 25, 1772; d. May 22, 1828. He studied at Poitiers and, to escape the French Revolution, emigrated to San Domingo (now Dominican Republic), where he published a journal, *L'ami de la paix et de l'union*. He was sentenced to death for the opinions he advocated but, by the timely assistance of the agents of the king of France, succeeded in escaping to Cape Francis (now Cap Haïtien), where he alone of 17 of his countrymen was saved from subsequent massacre in that city. He then visited the United States and England, and, on his return to Paris in 1797, prepared several dictionaries. His printing office was destroyed by fire, but the government employed him in various public capacities. In 1809, appointed secretary general of the commission houses, he was sent to Austria, and a year later was made inspector of Illyria. He became head of the Library Administration Bureau, served as secretary general of the Department of the Aisne, and prefect of St. Quentin. After a second visit to the United States he was commissioned to go to Guiana to study the climate and resources of that colony. His notes appeared in 1822. He became chief of the Bureau of Commerce and of the Colonies (1826) and commissary general of the interior (1828).

CATLETTSBURG, kât'lits-bûrg, city, Kentucky, seat of Boyd County, on the Ohio River at its confluence with the Big Sandy. It is on the Ohio and West Virginia borders, and on the Chesapeake and Ohio Railroad. Its industries include oil refining, chemical works, the manufacture of concrete products, and toys. Each June the American Folk Song Festival is held at "Traipsin' Woman's Cabin" which is nearby. The city was settled as a trading post in 1808 and has a mayor and council government. Pop. (1950) 4,750.

CATLIN, kât'lin, George, American traveler and artist: b. Wilkes-Barre, Pa., July 26, 1796; d. Jersey City, N. J., Dec. 23, 1872. After practicing as a lawyer for two years, he established himself in Philadelphia as a portrait painter and, in 1832, commenced special studies of the American Indians. He resided among them both in North and South America for many years. In 1840 he went to Europe, and subsequently introduced three groups of American Indians to European courts. His finely illustrated works are *Letters and Notes on the Manners, Customs, and Condition of the North American Indians*, 2 vols. (1841); *Catlin's North American Indian Portfolio . . .* (1845); *Catlin's Notes of Eight Years' Travels and Residence in Europe* (1848); *Life Among the Indians* (1867); *Last Rambles Amongst the Indians of the Rocky Mountains and the Andes* (1867). His 500 portraits from life of American Indians are now in the United States National Museum at Washington, D.C., constituting the Catlin Gallery. About 400 sketches are in the possession of the American Museum of Natural History, New York City.

Consult Miner, W. H., *George Catlin*, with an annotated bibliography of his writings (New York 1901); Haberly, Lloyd, *Pursuit of the Horizon* (Toronto 1948).

CATLINITE, kât'lin-it, a dull red indurated clay which was named for George Catlin (q.v.). It

occurs in Pipestone County, Minn., as a layer about 18 inches thick in quartzite. It has been manufactured by the Sioux Indians into pipes and various ornamental objects.

CATNIP or **CATMINT**, a hardy perennial herb (*Nepeta cataria*) of the family Menthaceae. Native to the Orient and Europe, it has spread to most temperate regions of the globe, including the Americas. Cats are especially fond of it, rubbing themselves upon it and eating it with relish. Catnip contains a fragrant volatile oil, for which it is sometimes used in cooking. It grows about two feet tall, bears heart-shaped greenish-white leaves and dense whorls of small purplish or rosy-white flowers.

CATO, kā'tō, **Dionysius**, reputed author of a Latin collection of moral maxims called *Dionysii Catonis Disticha de Moribus ad Filium*, though shorter titles appear. The author's aim was to inculcate courage, prudence, and moderation. The corpus, now reduced to 144 couplets in verse, with a preface and 56 proverbs, was cited first about 200 A.D. While various theories about its origin occur, most scholars suppose that between 117 and 324 A.D. the aphorisms were collected by an anonymous compiler and that Cato's name afterward was attached, because Cato the Censor had addressed sententious sayings to his son.

CATO, **Marcus Porcius** (known as **CATO THE CENSOR** or **CATO THE ELDER**), Roman soldier and statesman: b. Tusculum, near Frascati, Italy, 234 B.C.; d. Rome, 149 B.C. He also had the surnames of Priscus "the old-fashioned" or "the strict," and of Sapiens "the wise." The word Cato, derived from *catus* (sagacious), was first applied to him in the family, as his plebeian ancestors had been known simply as Marcus Porcius. The surnames Priscus and Maior were probably used later to distinguish Cato from his eminent great-grandson Marcus Porcius Cato Uticensis or Minor. In his boyhood Cato inherited from his father a small estate and there spent his adolescent years, until Hannibal's invasion of Italy incited the youth's patriotism. His first campaign was in 217 B.C., when he served under Quintus Fabius Maximus Verrucosus, the celebrated dictator, who later admitted Cato as an aide and schooled him in military science as well as indoctrinated him in political lore. Cato saw service at the sieges of Capua (214 B.C.) and of Tarentum (209 B.C.) and contributed to the decisive defeat of Hasdrubal at Sena Gallica on the Metaurus River (207 B.C.). During the winters, when belligerents rested, Cato resumed his labors on his farm and soon won local fame for his hardy mode of life, his sententious sayings, and his sound advice and decisions in local disputes. He soon attracted the attention of an influential neighbor, Lucius Valerius Flaccus, who belonged in Roman politics to the conservative and patrician party adhering to the old-fashioned, strict virtues of the ancient national character. Observing Cato's military record, eloquent speech, and homely rusticity, and knowing that all three assets were passports to a brilliant political career, Flaccus promised Cato his patronage if he would move to Rome and there enter politics. Cato accepted the offer and soon won recognition as an oracle of the austere, old-fashioned, religious-minded yeomen-citizen, who opposed the

sophisticated, intellectually refined, but morally degenerate element of Roman society, which had been captivated by Greek culture, then in its first flush of conquering Roman civilization.

In 204 B.C. Cato was chosen quaestor to Publius Cornelius Scipio—the victor over Hannibal at Zama—and assisted him in the transport of the Roman expeditionary force from Sicily to Africa. Cato took a dim view of Scipio's Hellenophilic conduct, extravagant expenses, and relaxed military discipline in Sicily, and denounced his general to the Senate. Though Scipio justified his management of the army and was acquitted, Cato's zeal in the cause of public interest increased his influence among the populace. Cato served as aedile in 199 B.C., and in 198 B.C. became praetor, obtaining Sardinia as his province. There he illustrated his principles by reducing official expenses, discarding pomp, installing an honest administration, and deciding cases with scrupulous impartiality.

When he returned to Rome in 197 B.C., Cato found that his reputation had preceded him and that at the age of 37 he had become a living legend for pure morality and antique virtue. His very faults—narrow patriotism, hostility to Greek culture (though he secretly studied Greek), old-fashioned practicality, rustic devotion to physical labor and to parsimony—carried the stamp of the national character and were pronounced to be virtues.

In 195 B.C. Cato attained the consulship and had Flaccus, his former patron, as his colleague. True to his principles, he resisted the rescission of the Oppian Law, passed in the dark days of the Hannibalic Wars to conserve money and materials, but was forced to yield to the popular protests that the flourishing conditions of the treasury warranted annulment of the law. Soon afterward he sailed for Spain to quell a rebellion. There he conducted such a vigorous and brilliant campaign that he soon reduced the peninsula to submission (though sullen and temporary as events proved), reformed its administration, and increased its revenues. His return to Rome in 194 B.C. was rewarded by a triumph. Cato's last military exploit was performed as legate of Manius Acilius Glabrio, consul in 191 B.C., during the war against Antiochus III of Syria, who had invaded Greece. Cato so distinguished himself at Thermopylae that Glabrio conferred much of the credit for the victory on him and sent him to report at Rome the successful conclusion of the campaign.

Henceforth Cato devoted himself to political warfare and, as a leader of the party opposed to Roman expansion in Greece and espousing the cause of the Italian peasant, he was active in senatorial debates, addressed the electorate frequently, and relentlessly pursued his opponents, particularly those who—according to his standards—had mismanaged provinces, or had been lax in accounting for military booty, or had been extravagant in expending state funds. Even if he did not directly intervene in the prosecution of the Scipios (Africanus and Asiaticus), it was certainly Cato who inspired the accusations of corruption made against them. Their political defeat enhanced Cato's position still further.

In 184 B.C. Cato achieved the acme of his ambition in obtaining the office of censor, wherein, with his old friend Flaccus as colleague again, he strove incessantly for moral, social, and economic reconstruction. One of the many anecdotes

illustrating his inflexible severity has it that Cato degraded from the Senate a praetor on the ground that he had kissed his wife in their daughter's presence. While some of his reform measures induced some obloquy and opposition, on the whole the people liked his performance and honored him with a statue and a laudatory inscription. Cato's last public commission was an embassy to Africa in 150 B.C. to decide a territorial dispute between Carthage and Numidia. He was so amazed at Carthage's rapid recovery from the last war and from its postwar losses to the Romans, that thereafter he ended every speech in the Senate—no matter on what subject he spoke—with the well-known sentence: "Moreover I vote that Carthage must be destroyed (*Praeterea censeo Carthaginem esse delendam*)."

He lived another year to see the outbreak of the Third Punic War which his voice had instigated.

Cato was married twice and had a son by each wife. His conduct as husband and father was equally exemplary, but he was a harsh master to his slaves, whom he chastised for trifling negligences and killed for graver offenses. Such brutality was, however, characteristic of his generation.

Cato also found time to write and, because the works of earlier writers have been largely lost, he has been called the father of Latin prose. We have: (1) fragments of his orations; (2) most of his treatise *De Agricultura* or *De Re Rustica*, containing miscellaneous materials on domestic and rural management; (3) many portions of his *Origines* in seven volumes, which traced Rome's history from the beginning to the year of his death; (4) some scraps of letters to his elder son, for whom he used this literary genre to discuss subjects suitable to a Roman youth's education.

Lives of Cato, written by Cornelius, Plutarch, and Sextus Aurelius Victor, survive and are supplemented by information gleaned from the historian Livy and from Cicero's *Cato Maior*, a dialogue wherein Cicero has Cato discuss old age, and *Brutus*, another dialogue in which Cicero characterizes Cato's oratorical style. All these, save Victor's brief sketch, are conveniently edited and translated in the Loeb Classical Library.

Bibliography.—Catonian fragments are edited by Hermann Peter, *Historicorum Romanorum Reliquiae*, vol. 1, pp. cxxvii-clxvii, 51-94 (Leipzig 1870); by Henrica Malcovati, *Oratorum Romanorum Fragmenta*, vol. 1, pp. 172-153-218 (Turin 1930); by Ernest Brehaut, *Cato the Censor on Farming* (New York 1933).

Consult Graves, J. T., "Cato" in *A Dictionary of Greek and Roman Biography and Mythology*, ed. by William Smith, vol. 1, pp. 635-644 (London 1880), still unsurpassed as the best biographical sketch in English; Corte, Francesco della, *Catone Censore* (Turin 1949); Marmorale, Enzo V., *Cato Maior*, 2d ed. (Bari 1949); Duff, J. Wight, *The Literary History of Rome*, rev. ed., vol. 1 (New York 1953), where the index for references to Cato, scattered throughout the work, should be used.

P. R. COLEMAN-NORTON,
Princeton University.

CATO, Marcus Porcius (surnamed UTICENSIS from Utica, place of his death), Roman patriot and Stoic philosopher; b. Rome, Italy, 95 B.C.; d. Utica, North Africa, 46 B.C. He was also known as Minor and the Younger to distinguish him from his great-grandfather Cato the Censor. Bereft of his parents in childhood, Cato was reared by his uncle first, then was educated by Greek tutors. Anecdotes about his boyhood confirm the adage that the child was the father of the man. Incorruptible, devoted to his concep-

tion of duty, simple and austere, practicing the strictest principles of Stoicism, rigidly republican in politics, consciously imitating his great ancestor, Cato represented during the degenerate and dying days of the free republic the old-fashioned virtues which had formed Romans into heroes.

Cato's earliest public appearance was against plebeian tribunes who were attempting to alter a basilica built by Cato the Censor, and in pleading his case he displayed that powerful eloquence which later made him so formidable. His first military campaign was in 72 B.C., when he volunteered in the Servile War against Spartacus. In 67 B.C., as military tribune, he commanded a legion in Macedonia, but saw little action. Elected quaestor in 65 B.C., he so honestly and efficiently conducted his office that the treasury was richer at the end of his tenure. Cato, who had inherited a large patrimony, spent the next year in travel in the province of Asia Minor, where he refused any offers of gifts to win his influence in the provincial interests. In 63 B.C. he won the election as one of the plebeian tribunes; the year was marked by the conspiracy of Catiline. Cato supported Marcus Tullius Cicero in proposing the death penalty for the plotters and his eloquence in the Senate turned the tide of votes, which had drifted toward Gaius Julius Caesar's proposal for life imprisonment. The Catilinarian conspiracy was only one symptom of gangsterism soon to ruin the republic. Cato and Cicero inveighed against prevailing political corruption and opposed the first triumvirate composed of Caesar, Gnaeus Pompeius Magnus, and Marcus Licinius Crassus, who secured control of the state in 60 B.C. To remove Cato from Rome the triumvirs sent him to add Cyprus to the provincial system; he occupied the island in 58 B.C. and accomplished his commission so efficiently that on his return he deposited in the treasury more money than any other provincial governor ever had.

About this time Cato's matrimonial life attracted public attention. Earlier he had divorced his first wife for adultery, after she had borne him two children. Later he remarried and became the father of three children. Now he amicably divorced his second wife for her to marry his friend Quintus Hortensius Hortalus, at whose death in 50 B.C. Cato received her into his home again.

Cato continued his fight against the triumvirs. Despite their opposition he finally gained (54 B.C.) the praetorship, highest office held by him. During his tenure he enforced the laws against corrupt electoral practices, thus alienating all parties, which considered it normal to buy and sell votes. He failed to attain the consulship because he refused to stoop to bribery. In 49 B.C., when the civil war between Caesar and Pompey began, Cato was appointed propraetor of Sicily, which he soon abandoned to the Caesarians' superior force in the hope that he could negotiate peace. He joined Pompey in Greece and had charge of his camp, while Pompey departed for his defeat at Pharsalia in 48 B.C. After the rout, Cato conveyed the republican remnants to Africa, where throughout 47 B.C. he assisted in rallying the forces against Caesar. When Caesar came to Africa to deal with the remaining republican army, Cato was left to hold Utica, while his colleagues marched bravely into the trap set for them by Caesar at Thapsus. All Africa, except Utica, then submitted to Caesar. Loathing life

under Caesar's despotism, Cato decided to die. After dinner, during which he talked about philosophy, he retired to his room and read Plato's discussion of immortality in the *Phaedo*. Then he stabbed himself. But his friends, awakened by his fall, ran to him and dressed his wound. When he recovered his senses, Cato removed the bandage, extracted his intestines, and thus died.

Besides Plutarch, whose biography (in the Loeb Classical Library) is our chief source, many ancient authors commemorate Cato, who became a popular subject of panegyric.

Consult Graves, J. T., "Cato" in *A Dictionary of Greek and Roman Biography and Mythology*, ed. by William Smith, vol. 1, pp. 645-650 (London 1880).

P. R. COLEMAN-NORTON,
Princeton University.

CATO, Publius Valerius, Roman scholar and poet: b. in Cisalpine Gaul, Italy, about 100 B.C. During the dictatorship of Lucius Cornelius Sulla (81-79 B.C.) and the confusion caused by the proscriptions, he lost his estate and went to Rome as a needy student. His talent as a critic and grammarian of the Alexandrian type eventually won him credit and distinction. Little of his works are extant; contradictory opinions exist as to whether two poems *Dirac* and *Lydia* should be attributed to Cato or to Virgil (q.v.).

CATO, the title of two noted 18th century plays: (1) A blank verse tragedy by Joseph Addison in five acts. It was first presented in 1713. The scene is laid in a hall of the governor's palace at Utica. The subject is Cato's last desperate struggle against Caesar and his determination to die rather than survive his country's freedom. *Cato* owed its extraordinary success to the deadly hatred that raged between the Whigs and Tories at the time: the Whigs cheered when an actor mentioned the word "liberty"; and the Tories, resenting the implied innuendo, cheered louder than they. To the Whigs the duke of Marlborough was a Cato, to the Tories he was a Caesar. Every poet of the time wrote verses in honor of *Cato*, the best being Alexander Pope's prologue; and it was translated into French, German, and Italian. (2) A tragedy, *Cato in Utica*, by Pietro Metastasio, in 1727. The author follows closely the historic accounts of Cato's relations with Caesar, and the details have more probability than those of Addison. He shows a decided superiority to Addison in making Caesar the principal figure next to Cato and in contrasting them constantly with each other.

CATO STREET CONSPIRACY or **THISTLEWOOD CONSPIRACY**, in English history, a plot formed in 1820 to murder the foreign secretary, Lord Castlereagh (Robert Stewart), and other cabinet ministers, and to form a provisional government. The leader of the conspirators was Arthur Thistlewood. The plot was discovered and several of the conspirators captured on February 23, when they had assembled in a stable on Cato Street and were preparing to carry out their intentions. Thistlewood, who escaped, was arrested the next day. After a trial in which they were defended by John Adolphus, Thistlewood and four others were executed, and five were transported.

CATONSVILLE, kă'tūnz-vīl, unincorporated village, Maryland, in Baltimore County, alti-

tude 500 feet, a residential suburb of Baltimore. Originally called Johnnycake, it was settled in 1729 and renamed about 1800. It is the site of the Spring Grove State Hospital for the Insane, of St. Charles College (1830; men), and of Mount de Sales Academy (1852; girls). John Wilkes Booth was a student at Catonsville Military Academy, 1851-1852. Pop. (1950) 29,638.

CATOPTRICS, kă-tōp'trīks, that branch of optics which explains the properties of incident and reflected light, and particularly that which is reflected from mirrors or polished surfaces. The whole doctrine of catoptrics rests on the principle that the angle of incidence is equal to the angle of reflection and in the same plane.

CATORCE, kă-tōr'sā, town, Mexico, in the State of San Luis Potosí, 15 miles west of Matehuala, situated on a barren spur of the Sierra Madre 9,045 feet above sea level, and containing some of the most valuable silver and antimony mines in Mexico. The town received its name, signifying 14, from a gang of robbers, formerly a constant menace to its inhabitants. There is also some mining of gold, lead, and copper, and the town's population varies greatly according to the demands of various minerals, sometimes leaping to 40,000 inhabitants. The railroad station, connecting the town with San Luis Potosí, which is 108 miles to the south, is 6 miles west of Catorce. Pop. (1940) 753.

CATOSTOMIDAE, kăt-ō-stōm'ī-dē, the suckers, a family of fishes of the order Eutrogna, to which many of the fresh-water fishes of the world belong.

This family has about 100 species in North America, with one species in Siberia and at least one in China. The shape of the body varies from thick and heavy to long and slender. The scales are smooth-edged, the head scaleless, and the jaws toothless, with the mouth so constructed that it can form a tubelike sucker through which food, consisting of plants and small animals, is drawn from the bottom of lakes and streams, the chosen habitat. The largest are the various buffalo fish, which may reach three feet in length.

A considerable fishery of suckers exists, centering along the Great Lakes and adjacent streams. They are taken commercially in gill and trap nets and afford some sport fishing. During spawning migrations into the shallow waters of lakes and streams, many are speared. The flesh, though bony, is sweet.

Consult Eddy, Samuel, and Surber, Thaddeus, *North-eastern Fishes* (Minneapolis 1947); Hubbs, Carl L., and Lagler, K. F., *Fishes of the Great Lakes Region* (Bloomfield Hills, Mich., 1947).

C. W. COATES.

CATRAIL (also known as the PICTS' WORK or PICTS' WORK DYKE), the name applied to the remains of a large earthwork in Scotland, about 48 miles in length, which, beginning at Torwoodlee Hill, near the junction of the Gala Water with the Tweed, runs with a semicircular sweep southward through the counties of Selkirk and Roxburgh to a point under Peel Fell, in the Cheviots. The trench ordinarily is 20 feet wide and 3 to 4 feet deep, with a rampart on each side, and the excavated earth lies usually on the lower side. Various causes have resulted in the destruction of the ramparts in many places. The origin of the Catrail has led to much

speculation, but is now supposed to have been a line of defense raised by the Britons against the invading Saxons.

CATS, *käts*, **Jakob**, Dutch poet: b. Brouwershaven, Zeeland, Nov. 10, 1577; d. Zorgvliet, near Scheveningen, Sept. 12, 1660. He studied at Leyden, Orléans and Paris. In 1627 and 1631 he was ambassador to England, and from 1636 to 1651 grand pensioner of Holland. His poetry is unimaginative and didactic, but has been extremely popular with the Dutch middle class by whom he is frequently affectionately alluded to as "Father Cats." A statue has been erected to him at his birthplace. His works consist of allegories, according to the taste of his times, poems on the different ages and situations of life, idyls, and the like. Among the most noted are *Het Houwelyck* (1625); *Sinne-en Minnebeelden* (1618); *Trouwingh* (1637); *Maegdenplicht* (1618); *Selfstryt* (1620); *Spiegel van den ouden en nieuwen tydt* (1632); *Faces Agustae* (1653).

CAT'S-EYE, the name given to several hard semitransparent stones used as gems, which, when cut in a certain way, show a line of light giving what is called a chatoyant effect. The true cat's-eye is a chrysoberyl of a greenish color, found in Ceylon and Brazil. The line of light shown when stone is cut *en cabochon* is due to the structure of the crystal, or to included impurities. The common cat's-eye, of little value, is a crystalline quartz sometimes containing fibers of asbestos, which, cut across the fibers, gives a chatoyant effect. It is found in Bavaria. Tiger-eye also shows the chatoyancy of the cat's-eye. Beautiful tourmaline cat's-eyes, rivaling the Oriental stones, have been found in California. Stones exhibiting the cat's-eye ray have been cut from various other minerals, including beryl, corundum, fibrous hornblende, bronzite, and hypersthene.

CATSKILL, *käts'kil*, village, N. Y., seat of Greene County, altitude 95 feet, 30 miles south of Albany, on Catskill Creek, on the west side of the Hudson River, and served by the New York Central Railroad. The Rip Van Winkle Bridge across the Hudson was completed in 1935. The village is a summer resort and gateway to the Catskill Mountain resorts. The Chase Memorial Law Library and St. Anthony's Seraphic Seminary (Franciscan) are at Catskill. The village manufactures women's wear and machinery, and ships apples and grapes, grown nearby. Catskill was settled about 1680 by Derrick Teunis van Vechten, whose homestead (1690) is still here. It is governed by a board of trustees. Pop. (1950) 5,392.

CATSKILL AQUEDUCT. See **AQUEDUCTS**.

CATSKILL GROUP, a name given to a great thickness of red, brown, green and gray conglomerates, sandstones and shales of which the Catskill Mountains are composed. Being well exposed by numerous cliffs and gorges, these deposits were carefully studied by the New York Geological Survey in the mid-19th century. The rocks were believed to constitute a series, having a definite place in the classification of the Paleozoic rocks worked out by the survey, and were

given the name Catskill. Subsequent investigation has shown that the Catskill is not even to be called a group. It is simply a succession of shoal-water deposits of Upper Devonian Age, which were laid down along one shore of an interior sea, while normal marine sediments, now represented by limestones, were being laid down elsewhere. Thus it happens that the Lower Catskill, of the Catskill Mountains, is represented elsewhere by limestones of the Hamilton stage, the Middle Catskill by the Portage and the Upper Catskill by the Chemung. In the Catskill Mountains the so-called Catskill series is 4,500 feet thick; and where thickest, at Mauch Chunk, Pa., it is 7,500 feet thick. Farther south the rocks thin out and disappear altogether in Virginia. Though having no standing as a rock group, the Catskill is of interest from its many resemblances to the Old Red Sandstone of England, made famous by Hugh Miller, and is of economic importance as containing some beds of excellent flags, quarried at numerous openings in Ulster, Greene and Delaware counties, N. Y., and sold as Hudson River bluestone. See also **DEVONIAN**; **OLD RED SANDSTONE**.

CATSKILL MOUNTAINS, a group of moderate elevation, part of the Alleghany Plateau, lying to the west of the Hudson River and situated mainly in Greene and Ulster counties, N. Y. The system covers about 1,400 square miles. The geological formation is very old, the mountains consisting of the shales and sandstone of the Catskill group of the Devonian system. The group contains several summits between 3,000 and 4,000 feet above sea-level. Slide Mountain, 4,205 feet, and Hunter Mountain, 4,025 feet, are the highest. The low lands along the creeks which drain the mountains and some uplands are cultivated. Many of the slopes form fine pastures; but the greater part is forested thickly with oak, ash, maple, beech, pine, and hickory. The pure atmosphere attracts eastern winter and summer visitors in large numbers, and the region is dotted with many resorts. Railways give access to many parts of the region. The Catskill watershed is a source of water supply for New York City.

CATT, *Carrie Lane Chapman*, American suffrage reformer: b. Ripon, Wis., Jan. 9, 1859; d. New Rochelle, N. Y., March 9, 1947. After graduating from Iowa State College in 1880, she studied law. Appointed principal of the Mason City (Iowa) High School in 1881, she became the city's first woman superintendent of schools two years later. In 1884 she married Leo Chapman, editor of the *Mason City Republican*. Shortly after her husband's death in 1886, she began to work for the woman suffrage movement, lecturing throughout the United States and Europe. In 1890 she was married to George W. Catt (q.v.). From 1904 to 1923 she was president of the International Woman Suffrage Alliance and served as president of the National American Woman Suffrage Association from 1915 until her death. In 1919 she founded the National League of Women Voters. Largely due to her organizing ability the 19th Amendment to the United States Constitution, enfranchising women, was adopted in 1920.

CATT, *George William*, American engineer: b. Davenport, Iowa, March 9, 1860; d.

1905. He was educated at the Iowa State College and subsequently studied engineering and law. He built government dry docks at the navy yards at League Island, Philadelphia, and Mare Island, Calif.

CATTANEO, Danese di Michele, Italian sculptor: b. Colonnata, near Carrara, 1509; d. Padua, 1573. He studied in Rome under Jacopo Tatti Sansovino (q.v.), and worked with him on sculptures in Venice. His own work there included the *Apollo* on the fountain in the Zecca, and the *Saint Jerome* in San Salvatore. In 1547 he completed the bust upon the tomb of Cardinal Pietro Bembo in the Sant' Antonio church at Padua. With Gerolamo Campagna, his pupil, he carved the tomb of Gian Fregoso in the church of Sant' Anastasia at Verona.

CATTARO, former name of a seaport in Dalmatia. See KOTOR.

CATTEGAT, a gulf between Denmark and Sweden. See KATTEGAT.

CATTELL, James McKeen, American psychologist: b. Easton, Pa., May 25, 1860; d. Lancaster, Pa., Jan. 20, 1944. He was graduated at Lafayette College in 1880, and studied at Leipzig, Paris, Geneva and Göttingen. He was professor of psychology in the University of Pennsylvania in 1888-1891 and professor of experimental psychology in Columbia University 1891-1896; from 1896 to 1902 head of the department of anthropology, and from 1902 to 1905 professor in the department of philosophy. He resigned in 1917. Besides publishing numerous papers on psychological subjects, he has edited numerous publications. He edited *The Psychological Review* (1894-1904) and *School and Society* (1915-1939), and he is editor of *Science* (since 1894), *The Scientific Monthly* (since 1900), *American Men of Science* (since 1906), *The American Naturalist* (since 1907) and *Leaders in Education* (since 1932-1944).

CATTERMOLE, George, English water color painter and book-illustrator: b. Dickleburgh, near Diss, Norfolk, Aug. 8, 1800; d. Clapham, Surrey, July 24, 1868. Like Joseph Mallord, William Turner and William Hunt, he started in life as a topographical draughtsman, and when only 16 years of age he was employed as a draughtsman upon John Britton's *Cathedral Antiquities of England* (14 vols., 1814-1835). In 1830 he visited Scotland to obtain materials for his fine series of illustrations to the *Waverley Novels* of Sir Walter Scott. Soon known as a brilliant illustrator, he was employed by publishers for the illustrations of various annuals. He illustrated the novels of Charles Dickens, an edition of Shakespeare and the *Historical Annual*, as well as his brother's *History of the Civil Wars*. As an artist he was distinguished by great versatility, and by considerable power of grouping and composition.

CATTLE.—The word cattle was at one time applied to many classes of livestock but its use today applies to animals of the bovine species. Cattle comes from the French word *catel* which is derived from Latin *capalle* or *capitale* meaning goods or property. The Biblical quotation (Psalms 50:10) "cattle of a thousand hills" undoubtedly referred to many classes of animals and Biblical commentators agree that cattle was associated with wealth.

The domesticated cattle, as we know them today, descended from wild forms that formerly lived in Europe and Asia. When and where cattle were first domesticated is unknown as it took place in prehistoric times. It is known, however, that man has been associated with cattle for many centuries. Naturalists have made extensive studies of bones found in ancient human dwelling places. Ancient and historical records, as well as works of art, depict the association of man with cattle. Fossil remains show that cattle existed in Europe before the glacial period but it has not been determined exactly whether our own domesticated cattle descended from this form or some other. Naturalists do not agree as to the classification of species but A. Keller, a German naturalist, states his conclusions to the effect that at one period there were two great races or breeds, namely, *Bos primigenius* and *Bos sondaicus* and attributes all of our modern breeds to either of these or to an admixture of both. The *Bos sondaicus* is believed to be the first type domesticated. This type may be described as having a broad, short head with short horns, which is characteristic of several European and English breeds such as the Shorthorn, Jersey and Guernsey.

The *Bos primigenius* may be described as a large powerful animal with long horns, long narrow head, which is typical of some present-day breeds such as the Holstein-Friesians. Selection, management, feed, climate, and other factors have been responsible for the development of the hundreds of breeds or strains of domesticated cattle scattered throughout the world. In England it is possible to see wild cattle in parks and on estates. They are known as the Chillingham cattle.

Another species known as *Bos indicus* is native to Asia and India. These cattle possess a hump over the shoulders and are called Brahman or Zebu. The term Brahman has been officially adopted as the correct name for descendants of these cattle in America.

There are really no cattle, as we know them today, native to America. The buffalo which roamed America before its discovery by the white man belongs to the same general class or same types of wild cattle that roamed Europe and Asia. All of the breeds in America have descended from cattle of Europe, Asia, and England.

Numbers and Distribution of Cattle.—According to statistics available in 1948 the 10 leading cattle-producing countries of the world were as follows:

Country	Number of cattle
India	200,000,000
United States	82,434,000
Brazil	42,000,000
USSR	41,500,000
Argentina	34,000,000
China	22,000,000
France	14,273,000
Australia	13,873,000
Colombia, S. A.	13,000,000
Union of So. Africa	13,000,000

According to estimates reported for 1947, the ten leading states of the United States in cattle numbers were:

Rank	State	Number of cattle	Value
1	Texas	8,754,000	\$609,278,000
2	Iowa	5,189,000	544,845,000
3	Wisconsin	3,962,000	586,376,000
4	Nebraska	3,882,000	354,815,000
5	Kansas	3,537,000	315,500,000
6	Minnesota	3,527,000	395,024,000
7	Illinois	3,303,000	376,112,000
8	Missouri	3,051,000	291,065,000
9	California	2,910,000	320,100,000
10	Oklahoma	2,724,000	195,038,000

Cattle along with some other animals such as the goat have cloven hooves and differ from the horse which has a solid hoof.

Cattle also differ from many other animals in that they have no front teeth on the upper mandible, their front teeth on the lower jaw meet with a membranous pad on the upper jaw when grazing on grass or other herbage. All cutting is done with lower teeth and grass is cut and pulled in the process of grazing.

The cow's stomach has four compartments, and she is classed as a ruminant. The compartments are known as the rumen, paunch, or first stomach; the reticulum, honeycomb, or second stomach; the omasum, manyplies, or third stomach; and the abomasum, or true or fourth stomach. Food eaten by the cow first enters the rumen, where it is stored for a time while being softened and somewhat mascerated. During repose the cow forces small quantities of the food back into her mouth and rechews it into a small ball or cud. After chewing or ruminating on each cud for a time she swallows it into the second stomach. The first three compartments are mainly for storing the food material, true digestion taking place in the fourth stomach and finally in the intestine.

Chemical, bacteriological, and other digestive processes take place during the course of the food through these compartments and the intestines and the resultant materials are taken up in the blood stream to produce muscular and bone tissue, body growth, and milk.

In general, the domestic cattle may be divided into classes or types, namely dairy, beef, and dual purpose. In reality all types are dual purpose since they all produce milk and the carcass is used for meat. The dairy type, however, has been developed for the prime purpose of producing milk. Selection has given the dairy cow a distinct type of body, being angular or wedge-shaped, with a long, thin neck and lean shoulders, large barrel, and large spacious udder. Beef type cattle have short necks, smooth wide shoulders, wide breasts, large heart girth; they are well muscled and smooth over the back and loins, and have heavy hind quarters.

The following breeds are represented by the cattle of the United States:

Dairy breeds	Beef breeds
Ayrshire	Shorthorn
Brown-Swiss	Polled Durham
Holstein-Friesian	Hereford
Guernsey	Aberdeen Angus
Jersey	Galloway
	Santa Gertrudis
Dual purpose	Minor breeds
Milking Shorthorns	Dutch Belted
Red Poll	Red Sindhi
	Red Danish
	Devon

Dairy Breeds.—The dairy breeds or strains of cattle originated from the same foundation

stock as the beef breeds or dual-purpose breed. During the past century, perhaps more progress has been made in the improvement of dairy cattle than in most other classes of livestock. As a result of intelligent and careful selection, aided by measurements of milk production, the improved dairy cow is now a highly efficient and profitable farm animal. The original cow gave only enough milk to rear her calf. Today some cows give enough milk in a year to raise 20 calves. Improvement of the dairy cow has lengthened her lactation period, from a few months to a year or more. The butterfat content of the milk of certain breeds has likewise been improved. The tendency to lay fat on the body has been eliminated to a great extent in the dairy cow, and her efficiency in the production of human food has been greatly increased as compared to the special purpose breeds.

The following table shows the comparative amount of dry matter in the carcass of a fat steer weighing 1,250 pounds and in the milk produced by a Holstein Friesian cow in one year.

	Milk, 18,405 pounds	Steer, 1,250 pounds
Proteids	552 pounds	172 pounds
Fat	618 "	333 "
Sugar	920 "	" "
Ash	128 "	43 "
Total	2,218 pounds	548 pounds

The 2,218 pounds of dry matter from the year's production of the dairy cow was all edible and digestible, while the 548 pounds of dry matter produced from the carcass of the steer included the bones, hair, and all of the organs of digestion, respiration, and circulation. Individual cows of the several breeds have produced much more milk than the cow shown in the table. Some Holstein cows have produced more than twice as much milk in a year.

Ayrshire cattle originated in southwestern Scotland in the latter part of the 18th century, in the county or shire of Ayr. Little is known of the origin of this breed but it is certain that it resulted from crossing cattle of various breeds. The first importation into the United States was in 1822 and Ayrshires are now found in nearly every state in the Union. Many Ayrshires are also found in Canada and in northern Europe. In size the Ayrshire cow will average around 1,100 to 1,200 pounds and the bulls from 1,500 to 2,000 pounds. The color of this breed is usually red and white. Individual animals may be nearly all white or red, or show broken color of red and white. The cows are good milkers averaging to produce around 9,000 to 10,000 pounds of milk per year with an average butterfat content of 4 per cent. Several cows of this breed have produced more than 20,000 pounds of milk and 900 to 1,000 pounds of butterfat annually. The cows fatten readily when dry and make an acceptable quality of beef. Many farmers prefer Ayrshires because of their beef-making tendency. One of the particular characteristics of Ayrshires is their rather long horns, which curve upward and backward. A strain of polled Ayrshires (without horns) has been developed in the United States.

Brown-Swiss cattle originated in Switzerland and are classified as dual purpose there, or even as triple purpose cattle, since they are used for milk, meat, and work. The color ranges from a light gray to a dark gray or brown. The cattle have large frames, mature cows weighing about 1,100 to 1,500 pounds and mature bulls 1,500 to

2,300 pounds. The young calves at birth are solid white but as they grow older they change to the characteristic color for the breed. Representative cows of this breed will produce from 10,000 to 12,000 pounds of milk annually and it contains on the average about 4 per cent of butterfat. Several cows of the breed have made official records of over 22,000 pounds of milk and 1,000 pounds of butterfat per year. The first importation of Brown-Swiss cattle into America was made in 1869.

Holstein-Friesian cattle originated more than 2,000 years ago in western Europe, in the area now known as Holland or Netherlands. The first importation into America was in 1795. This is a horned breed and they are black and white in color. Some may be almost solid black and others almost solid white, but they are not acceptable to the breeders unless they have some white and black on the body, head, or legs. This is the largest breed of dairy cattle, and in their native country the animals are used for milk, meat, and work. Mature cows weigh from 1,200 to 1,800 pounds and mature bulls from 1,600 to 2,400 pounds. In milk production the cows of this breed exceed all other breeds. Mature cows will average to produce 10,000 to 15,000 pounds of milk annually, with a butterfat test of about 3.4 per cent. Many mature cows of the breed have produced more than 30,000 pounds of milk and 1,000 pounds of butterfat annually. Some have made yearly records of over 40,000 pounds of milk and more than 1,200 pounds of butterfat. The Holstein-Friesians are the most popular of all the dairy breeds as milk producers. It is estimated that nearly 70 per cent of all milk produced by dairy cattle in the United States comes from Holsteins. They are particularly popular for producing market milk near our large cities. Cattle of this breed are to be found in every state in the United States and are known and used in all countries.

The *Guernsey* breed originated on the island of Guernsey, one of the islands in the English Channel, where it has been kept pure for several centuries. In the early stage of the development of this breed, all cattle in the Channel Islands were known as Alderney cattle. Importation of cattle of any kind to Guernsey Island or to other islands in the group has been prohibited except for slaughter for many decades. Guernsey cattle resemble the Jersey in color, which may range from a reddish yellow to lemon or orange, with white markings. They are larger than the Jersey, have bigger bones, and are somewhat more rugged. Cows weigh 900 to 1,000 pounds and bulls weigh from 1,600 to 2,000 pounds when mature. One of the outstanding characteristics of this breed is the deep yellow color of the milk. The Guernsey Breed Association has been quite successful in popularizing the product of its breed under the name of Golden Guernsey milk. Mature cows of good breeding will average 8,000 to 10,000 pounds of milk, with an average butterfat content of 4.5 to 5 per cent. The number of registered Guernseys in the United States is second only to the Holstein-Friesians. The first importation into the United States was made in 1833.

Jersey cattle originated on the island of Jersey in the English Channel and the breed has been kept pure there for more than 100 years. Laws prohibiting importation of breeding cattle into the island have prevented any admixture of a

foreign breed. Earliest importations into the United States were made in 1850. The color is some shade of fawn ranging from a very light shade to almost black. White markings may appear on animals and are referred to as "broken color."

The females at maturity weigh from 800 to 1,000 pounds and some attain a greater weight; the mature bulls weigh from 1,200 to 2,000 pounds. This breed is noted for the production of milk rich in butterfat, excelling all other dairy breeds in this respect. Mature cows will produce from 6,000 to 10,000 pounds of milk, with an average butterfat test of about 5 per cent. Many cows of this breed have produced more than 18,000 pounds of milk and 1,000 pounds of butterfat in a year. The Jersey is highly prized as a family cow.

Beef Breeds.—The breeders of strictly beef cattle have made a tremendous improvement in the various breeds. This is borne out by photographic records showing the change that has taken place in the type of cattle shown at fairs 40 to 50 years ago as compared with the modern type. Noticeable changes resulting from selection and breeding are the shorter legs and earlier maturity of modern breeds.

It has been more difficult to make progress in the breeding of beef cattle than in breeding dairy cattle, in that no definite yardstick has been developed for measuring improvement in the individual animals as is possible with dairy cattle, where production records of milk and butterfat are the yardstick for measuring progress.

Attempts have been made to develop standards through feeding tests. In such tests records are kept of the gain in weight from birth to slaughter; records of all feed consumed during the same period, and a slaughter score based on dressing percentage and physical and chemical characteristics of the cooked meat are designed to be used to measure the difference between the individual animals from known parentage. Such tests will be invaluable as a means of selecting breeding stock to improve meat production. In some strains or families of certain beef breeds, the beef characteristics have been developed at the expense of the dairy or milk characteristics until the cows give very little milk; in many cases they do not give enough milk to nourish their calves properly.

Shorthorn cattle originated in England and first came into prominence during the latter part of the 18th century. They were imported into the United States as early as 1783. The color is red, red and white, white, or roan which is a mixture of red and white hair over the entire body. Mature cows weigh from 1,300 to 1,800 pounds and mature bulls weigh from 1,800 to 2,500 pounds. This breed is highly prized in the corn belt and they are economical producers of meat of high quality. The cows are usually good milkers as compared with other beef breeds. Shorthorn cattle are known all over the world and can be found in almost any country. The true Shorthorns are horned cattle.

Hereford cattle are native of England and were developed in Herefordshire in the western part of that country. They were first imported into the United States about 1820. Cattle of this breed are sought after by ranchmen because of their ability to rustle for their feed. They are large cattle, although smaller than the Shorthorn. The main portion of the body is red and the

face is white. Hence the term "white-faced cattle" as they are generally known. White markings are found on legs, on lower part of belly and brisket, and on top of neck. The cows usually weigh 1,300 to 1,500 pounds and the mature bulls from 1,500 to 2,300 pounds. One of the outstanding characteristics of the breed is early maturity. There are more cattle of this breed on the range country in the United States than of any other beef breed. This is generally known as a horned breed, but there are a considerable number of polled Herefords in the United States.

Aberdeen Angus cattle originated in Scotland. They are a hornless breed and are often referred to as polled Angus. The color is black, but occasionally a red animal may be born in a purebred herd. Red is undesirable from the purebred breeder's standpoint, however, and such animals are culled out. Angus cattle are very popular in the corn belt. Mature cows weigh from 1,200 to 1,500 pounds and bulls weigh from 1,600 to 2,000 pounds or more. Breeders often cross their Angus females with pure white Shorthorn bulls to produce blue-gray or blue-roan steers, which are highly prized by feeders. The quality of beef of the Angus is excellent.

Galloway is another breed which had its origin in Scotland. Typical cattle of this breed are low, blocky animals, with a long, soft, shaggy coat of black hair. The breed is hornless. Galloway cattle are adapted to cold climates and they are excellent rustlers for feed. They have not proved as popular as the other principal beef breeds.

The *Santa Gertrudis* breed had its origin in the United States. It is red in color and represents a cross of Brahman cattle with the Shorthorn. The Brahman cattle have certain characteristics that make them well adapted to warm climates in tropical and subtropical areas. The cross which has been pretty well established and will reproduce is a mixture of about five eighths Shorthorn blood and three eighths Brahman blood. Cows weigh 1,200 to 1,500 pounds and bulls weigh 2,000 pounds or more when mature. The color is red, they have a very deep body, good beef conformation, are very hardy and seem to be particularly adapted to southern range conditions. There has been a good demand for these cattle. They have the quality of heat resistance, are good rustlers and are not as susceptible to certain diseases as other cattle. Other crosses have been made with Brahmans and Herefords as well as with Aberdeen Angus.

Dual Purpose Cattle.—The *Milking Shorthorn* is perhaps the most popular dual-purpose breed known today. The origin of this breed is the same as that of the Beef Shorthorn breed. The dairy production is a result of selection and mating animals of heavy milk production. The color is red, red and white, and roan. These cattle are very popular in the general farming areas in the United States and in other countries. The cows usually weigh from 1,200 to 1,500 pounds. Some cows have made excellent milk records, giving more than 18,000 pounds per year; the average, however, produces from 6,000 to 8,000 pounds of milk with an average butterfat test of 3.5 to 4 per cent. The cows fatten readily when dry; the calves, being quite large at birth, are much more valuable for veal, or to feed out as steers, than the calves of the special dairy breeds.

Red Polled cattle, as signified by their name, are red in color and do not have horns. They originated from cattle that existed in Norfolk and Suffolk, England. They are much sought after as dual-purpose cattle. Some breeders emphasizing the dairy potentialities have produced cows with records of 20,000 pounds of milk per year. The average test for butterfat is about 4 per cent. Red Polled cattle are very popular in the corn belt, where the farmer desires to run a dairy and at the same time wants to use the steer calves to produce good meat animals. Cattle of this breed cross well with other breeds such as the Shorthorns. They transmit a red color and the polled character quite uniformly.

Minor Breeds.—There are several minor breeds of dairy cattle but they are of no great economic importance and there are relatively few in the United States.

Dexter Kerry cattle originated in Ireland, are black in color and small in size, even smaller than the Jersey, but they are not equal to the Jerseys as milk producers.

Devon cattle had their origin in Devonshire in England. They are a horned cattle and are red in color. Some breeders have specialized in developing the beef type and others have followed a dual-purpose type. There are only a very few of these cattle in America. In the early days the Devon oxen were highly prized as draft animals.

The *Dutch Belted* breed originated in Holland, where it is classified as a dairy breed. This breed was developed by selection from other types or breeds, very largely on the basis of color. The desired markings are solid black with a white stripe encircling the body between shoulder point and the hip. The greatest interest manifested in this breed since its origin has been by those who wanted something different. Only a few cattle of this breed ever left Holland. There are several hundred in the United States.

In Canada the *French Canadian* cattle are classified as a dairy breed. They are largely confined to Canadian farmers' herds, and are only fair producers of milk and butterfat.

Red Sindhi cattle, which belong to the Brahman or Zebu type of cattle, are native to India and are rated as a dairy breed in that country. In 1946, four head (two males and two females) were imported by the United States Department of Agriculture for the purpose of developing a strain of dairy cattle for tropical and subtropical areas. This breed, in common with all Brahman cattle, has the ability to resist high temperatures and it is also more or less resistant to certain diseases and pests. The purpose in bringing these animals to America was to cross them with certain dairy breeds with the hope of capturing at least a part of their resistance to heat. Experiments in crossing the Red Sindhi with dairy breeds are being conducted at Jeanerette, La.

Red Danish cattle originated in Denmark and make up 95 per cent of the total number of cows kept for milk in that country. They were developed by crossing the native cattle of Denmark with other known breeds. They are of particular interest because the average production of milk and butterfat is higher per cow in Denmark than in any other country in the world. The first and only importation of Red Danish cattle into America was in 1935. They are held in great favor by those who have had experience with them. They might be classed as a dual-purpose

Herd Books.—It is customary in almost all countries, where distinct breeds are known to exist, to have a registration system or herd book in which records of birth and parentage of individuals are kept. Cattle registered in such herd books are often called purebred cattle, but they should be more appropriately called registered cattle. The various herd books were founded by the specific breed associations or societies and usually they are operated under their direction. In some countries, however, the government operates the herd books. In addition to keeping records, the breed associations publish educational and other informational booklets and pamphlets concerning the merits of their breed. The dairy breed associations in most countries also keep a separate record referred to as an advanced register or register of merit. The milk and butterfat records of individual cows and herds and other detailed information are published for the information of breeders.

In the United States, England, Denmark, and certain other countries, a system of keeping records of milk production and feed costs is encouraged by government agencies. In the United States, dairy farmers organized dairy-herd-improvement associations or cow-testing associations, with the help of federal and state extension services, for the purpose of keeping records on all cows on their farms. The first cow-testing association was organized in Denmark in 1895. The first one in the United States was organized in 1906. Information obtained by this cooperative effort serves as a guide to each herd owner in breeding, selection, and feeding of dairy cattle for more economical milk production. The effectiveness of such practices is evident in the fact that in 1947 nearly a million cows were enrolled in herd-improvement associations and their average yield was 8,638 pounds of milk and 348 pounds of butterfat per cow, as compared with an average of 5,000 pounds of milk and 199 pounds of butterfat for all other cows milked in the United States.

Proved Sires.—Cattle breeders have long appreciated the value of a sire that proved to have the ability to beget uniform and productive offspring. Dairymen have given more attention to the development of proved sires during the past 30 years than heretofore. The method of proving a dairy sire is to test his unselected progeny by keeping milk and butterfat records on each individual for at least one year and comparing such records with those of their dams when made under similar feeding and environmental condition. The sires whose daughters show an increase in production over the records of their dams are termed meritoriously proved sires and are much sought after by individual breeders as well as by the artificial-insemination associations. A requirement usually set up is to compare at least five unselected daughters with their five dams; however, it is much better to have a larger number for this comparison. Some 4 or 5 years is required to prove a bull, from the time he is ready for service until his daughters complete their first lactation period. Through the continuous use of good proved sires it is possible to develop a herd of dairy cattle in a few generations that will be nearly pure in their inheritance for high milk and butterfat production.

Crossbreeding.—During the past few years

considerable effort has been made to study the effect of controlled crossbreeding in both beef and dairy cattle. This practice in breeding other kinds of livestock and poultry, as well as with many plants has met with considerable success. As an example of the work of crossing dairy cattle the following data are from an experiment conducted at the Agricultural Research Center of the United States Department of Agriculture at Beltsville, Maryland.

Two and three breed combinations of Jersey, Guernsey, Holstein-Friesian, and Red Dane cattle were made. A two-breed cross resulted when a male of one of these breeds was mated to a female of another. Three-breed crosses were made by mating such two-breed females to a proved sire of a third breed.

The measure of producing ability was the amount of milk and butterfat produced when milked three times daily for 365 days in the first lactation period. Records completed thus far show the following average production:

	Number	Milk lbs.	Butterfat %	Age at calving lbs. Yrs. Mths.
Two-breed crosses	50	12,958	4.56	586 2 2
Three-breed crosses	27	13,130	4.64	618 2 2

Artificial Insemination.—One of the great developments now being used to improve cattle, particularly dairy cattle, is the artificial-breeding organization. The USSR and Denmark have been leaders in this new method of improvement. In 1948 artificial insemination with dairy cattle was followed in many countries.

Through artificial insemination it is possible to breed 10 to 100 times as many cows to one bull as with natural service. There are many advantages in the use of this method. One big advantage is that it is not necessary to keep a bull on every farm. Another is that semen is usually available from a better-bred sire than would otherwise be the case, especially for small herds. Proved sires are very much in demand for use in artificial-breeding associations. Farmers organize artificial-breeding associations, establish a central unit of good bulls, and then employ technicians to handle the program. During the year 1947, 1,700,000 dairy cows were bred artificially in the United States. The average service for each sire used was about 500 cows. This plan, if properly managed and operated, offers the greatest method yet devised for mass improvement in dairy cattle.

Cattle Feeding.—Cattle subsist largely on pasture grasses and other roughages, either in the fresh green state or cured as hay—many crops such as the legume hay crops, corn, soybeans, and sorghums are stored in a silo as roughage feeds. In the feeding of a herd of either beef or dairy cattle they should have access to all the good roughage (pasture, hays, silage, etc.) that they can consume and an additional amount of concentrates (grain) to make up the total nutrients required for growth or milk and meat production. Definite standards for feeding cattle, young or old, beef or dairy, have been worked out on an accurate basis and are available in texts and references given at the end of this article.

In general, dairy cattle will make a greater return on high-priced land than will beef cattle. Beef-cattle herds are more adapted to the ranges where feed can be more economically produced. See also CATTLE, DISEASES OF.

O. E. REED,

Chief, Bureau of Dairy Industry, United States Department of Agriculture.

CATTLE, Diseases of. Since the cow is the foster mother of the human race, diseases of cattle are second in importance only to those of man himself. It is significant that only those nations which control and prevent diseases of their cattle and other livestock are well fed.

INFECTIOUS DISEASES

Many serious and destructive diseases of cattle are caused by infectious agents, such as viruses, bacteria, protozoa.

Foot-and-Mouth Disease.—Because of its extreme infectiousness, its rapid spread, and its devastating effects, foot-and-mouth disease is one of the most feared of all the maladies attacking livestock. It strikes both domestic and wild cloven-footed animals, such as cattle, sheep, goats, swine, camels, deer, buffaloes, antelope, and giraffes.

For decades this disease has been well established in most areas of the Old World. It is now found also in most of the principal cattle-producing countries of South America. Until it appeared in Mexico during 1946, North America had been free of it except for 10 outbreaks, none of which had become firmly established. Eight of these involved the United States only, one included both the United States and Canada, one was restricted to Mexico. The most widespread of these occurred in the United States during 1914-1915. It invaded 22 states and the District of Columbia. The 1946 invasion of Mexico appeared first in the state of Vera Cruz and soon spread into 17 states and the Federal District, a territory containing approximately 15 million cloven-footed animals.

Australia, New Zealand, the Union of South Africa, Colombia, Canada, the United States, and Ireland are free of foot-and-mouth disease.

Cause.—The cause of this disease is a virus, much too small to be seen with the usual high-power microscope. This virus lives and multiplies in the tissues of affected animals, especially the membranes of the mouth and tongue, the skin between the hoofs, and the lining of the first stomach. It is present in the blood, milk, saliva,

urine, flesh, and bones of infected animals. There are at least three types of virus: recovery from an attack by one of these does not protect against either of the others.

Method of Spread.—The most common method of spread is through contact of susceptible animals with infected animals or animal products. But it may be transmitted by such factors as infected hay or straw, persons who have come in contact with the virus, infected premises or railroad cars. The incubation period is very short; symptoms usually appear within three to seven days after exposure.

Symptoms.—As the name indicates, the mouth and the feet are usually affected. Blisters or vesicles form on the tongue, in the lining of the mouth and lips, between the toes, and around the top of the hoofs. These blisters soon rupture and leave reddened, shallow ulcers. Affected animals eat very little, have fever, lose weight rapidly. If the feet are affected, lameness may be very severe. Cattle with the disease may drool with ropy saliva hanging from the lips. Cows in milk show a rapid and marked decrease of milk production and pregnant cows may abort.

Mortality is high among very young calves and old, heavy bulls. Most mature animals in good condition recover, but the convalescent period is rather long, because lameness persists after the active stage of the disease has passed, and the ulcers in the mouth require time to heal.

Diagnosis.—In typical outbreaks the rapid spread of the disease, its ability to attack all types of cloven-footed animals, and the severity of the symptoms help in making a definite diagnosis. But it may be necessary to make experimental inoculations and laboratory tests, as two other diseases also cause similar formation of vesicles.

Treatment.—No satisfactory treatment has been found.

Control and Eradication.—Foot-and-mouth disease is so infectious that quarantine alone usually fails to prevent its spread. During the 1940's the use of a new vaccine combined with quarantine became rather general. Although the vaccine gives rather good protection, its effect is not permanent. Consequently it is necessary to revaccinate at frequent intervals to insure continued resistance. Furthermore a vaccine made with one type of virus will not protect against either of the other two. In most areas where vaccination and quarantine measures have been combined, the prevalence of the disease has been reduced considerably and losses have decreased markedly. But attempts at complete eradication through vaccination and quarantine alone have been unsuccessful.

On the other hand, slaughter of affected and exposed susceptible animals, strict quarantine, and thorough cleaning and disinfection of infected premises have been repeatedly successful. Outbreaks in the United States since the federal Bureau of Animal Industry was organized (1884) have been exterminated by these procedures. Other countries have used them with equal success. The United States is firmly committed to this method of handling outbreaks.

A combination of these measures and vaccination has been used in Switzerland and since 1946 is being applied in Mexico. In the latter country quarantine lines demarcate the infected area from the disease-free areas. Attempts to inspect every cloven-footed animal within the infected zone at

30-day intervals are made. Every animal found to have foot-and-mouth disease and any unvaccinated, exposed, susceptible animal is destroyed and buried. Infected premises are cleaned, disinfected, and quarantined until they are proved by tests to be free of infection. All cloven-footed animals within the quarantined area of Mexico are vaccinated every four months.

During the last six months of 1949 foot-and-mouth disease was found on less than a dozen premises in Mexico. In that period more than 20 million doses of vaccine were used.

Prevention.—Obviously it is very expensive to try to protect a country from foot-and-mouth disease through vaccination. But the United States, Canada, Australia, and New Zealand have proved that the disease can be excluded for long periods of time by strict quarantine, combined with constant watchfulness and vigorous extirpatory measures, if the disease does appear.

Economics.—A livestock-producing country would find it advisable to spend comparatively large sums of money for preventive measures rather than to have foot-and-mouth disease become firmly established in it. The outbreak in Germany during 1911 is said to have attacked more than 14 per cent of its approximately 50 million cloven-footed animals in spite of governmental attempts to control it. Switzerland, with a livestock population about one fiftieth of that of the United States, is reported to have lost about 70 million dollars from the outbreak in 1920-1921. An invasion of similar severity in the United States would cost this country over 3.5 billion dollars.

Rinderpest.—This acute, infectious disease attacks cattle, sheep, goats, and buffaloes. It occurs in Asia and in Africa and has invaded Europe occasionally.

Cause.—The cause is a virus too small to be seen with a high-power microscope. So far as is known, this virus does not multiply outside the body of a susceptible animal. It is present in the tissues, blood, urine, and evacuations of infected animals. It spreads from animal to animal by direct contact or by such intermediate carriers as infected hay, implements, and utensils, persons with the virus on their shoes or clothing, and infected premises.

Symptoms.—Affected animals develop severe symptoms rather quickly. They have high fever, rapid loss of weight and marked debility. Diarrhea is a very common symptom. The dung may be streaked with blood, especially in the later stages of the disease. Coughing with a discharge from the nose is common. Fully susceptible cattle usually die in 4 to 10 days after attack.

Treatment.—As in most acute infectious diseases, no satisfactory treatment is known.

Control and Eradication.—Vaccines which produce satisfactory immunity against rinderpest have been developed and tested on a rather large scale under field conditions. When widely used and combined with quarantine, they effect control of spread and very marked decrease in losses. But unless there is excellent enforcement of quarantine and vaccination regulations, the disease may smolder for months, only to recur when unvaccinated calves are raised. In countries where the disease recently has been introduced and consequently is not widespread, slaughter of infected and exposed animals, together with quarantine measures, has been successful in eradicating it completely.

Prevention.—Countries free of rinderpest, like the United States, maintain quarantines against infected areas.

Contagious Pleuropneumonia.—During the 19th century this very destructive disease of cattle caused serious losses in most of the countries of Europe, Asia, and Africa. It has invaded the United States several times, the first probably being in 1843.

Cause.—The organism causing contagious pleuropneumonia, *Asterococcus mycoides*, is smaller than most bacteria but larger than typical viruses. This agent lives in the lungs and other tissues of infected cattle. It usually spreads by direct contact between infected and susceptible animals, but can be transmitted indirectly through such media as infected barns, premises, railroad cars.

Symptoms.—As the name implies, this disease attacks the lungs and the pleura which covers them. In acute cases symptoms develop suddenly with rapid breathing, coughing, high temperatures, loss of weight. Animals so affected usually die in one to three weeks. In chronic cases symptoms develop more slowly. The coughing, scarcely noticeable at first, becomes pronounced, breathing is rapid and labored, the appetite decreases, and there is constant loss of weight. In the later stages, when most of the lung tissue is affected, the animals stand most of the time. When some chronic cases have only mild symptoms, recovery soon follows. Recovered animals may be carriers of the disease for a long time after symptoms have disappeared. In some herds nearly all the cattle contract the disease soon after its introduction, whereas in others it spreads slowly and many animals escape.

Treatment.—No satisfactory method of treatment exists.

Control and Eradication.—Many countries have eliminated this disease since 1860. Successful measures of eradication include slaughter of all infected and exposed cattle, strict quarantine of infected premises until they are thoroughly cleaned and disinfected, and periodic inspection to detect new centers of infection. Although these measures may seem severe and expensive, they are much preferable to living with the disease. By following them the United States and many other countries have eradicated contagious pleuropneumonia. No case has been found in the United States since 1892.

Prevention.—Strict quarantine prevents entry of this disease into countries which are free of it.

Tuberculosis.—Long a scourge of the cattleman and the dairyman, it is found in practically every part of the world where there is a considerable population of cattle. In countries having a heavy concentration of dairy cattle, the disease is usually prevalent and affects 10 to 40 per cent of the cattle.

Cause.—The cause is the bovine type of the tuberculosis organism, *Mycobacterium tuberculosis bovinus*. This germ may produce tuberculosis in many other species of animals, including man. As far as is known, under natural conditions it does not multiply outside an animal's body. However, it will live for many months in barns, stables, or yards, if it is protected from direct sunlight. These germs may escape from infected cattle in the dung, the urine, the milk, and the saliva. Infection may gain entrance into susceptible cattle from contaminated feed, milk, or water, by inhalation of infected materials, or through cuts or abrasions of the skin.

Symptoms.—It cannot be stressed too strongly that many cattle with generalized tuberculosis are in good physical condition and appear healthy. However, such animals may be active spreaders of disease.

Since tuberculosis is a chronic disease, symptoms usually develop slowly. Their character varies according to the organs affected. Thus cattle with tuberculosis of the liver and intestines may develop a persistent diarrhea, whereas those with affected lungs usually have a chronic cough. If the udder is attacked, the affected quarters may enlarge and become firm without being hot and painful. As the disease progresses, most affected cattle develop a rough coat, become unthrifty, and lose weight. Most animals which develop symptoms finally die of the disease.

Diagnosis.—Tuberculin is used widely as a diagnostic agent, since thousands of critical experiments have proved that it is very accurate. It is made by growing tuberculosis organisms on artificial culture media, destroying the germs by heat, and filtering out the dead organisms. It never can cause tuberculosis, because it never contains living organisms.

Of the three tests with tuberculin, the intradermic test is most widely used by veterinarians. It is made by injecting tuberculin into the skin and observing the point of injection 72 to 120 hours later. Reactors develop a characteristic swelling at the injected spot. The subcutaneous test is made by injecting tuberculin underneath the skin. Tuberculous animals show a rise in temperature after injection. Since the temperature of each tested animal must be taken six to 10 times, the subcutaneous test is much more time-consuming than the intradermic test. The ophthalmic, or eye, test is not in general use, because most veterinarians who have tried it extensively believe it inferior to the intradermic test.

Treatment.—No satisfactory treatment for tuberculous cattle has been discovered.

Control and Eradication.—The experience of the United States and several other countries has proved that bovine tuberculosis can be controlled and eradicated. The successful method consists in locating the infected cattle by applying the tuberculin test, slaughtering them, cleaning and disinfecting the premises, and retesting until no reactors are found.

Officials of the federal Bureau of Animal Industry and state veterinary officials launched in 1917 a cooperative campaign to exterminate tuberculosis. For the first few years efforts were confined mainly to individual herds, but the program was changed gradually to area testing. A method of accrediting counties as being modified tuberculosis-free, when infection had been reduced to less than 1.5 per cent, was developed. When this program began, it was estimated that from 8 to 10 per cent of all dairy cows and from 1 to 2 per cent of all beef cows in the United States were tuberculous. In 1922, 4.2 per cent of all tested cattle reacted. In 1936, only 0.5 per cent of the tested cattle were reactors and by Nov. 1, 1940, every county in the country had attained the modified tuberculosis-free status. Only 0.19 per cent of the approximately 8 million cattle tested in 1949 were reactors.

In the United States untested cattle are not allowed to be moved in interstate commerce, except for immediate slaughter, unless they originate from accredited herds or modified accredited areas. Strictly enforced regulations require that

all imported cattle be accompanied by satisfactory official records showing that they are free of tuberculosis.

Bang's Disease.—This is, without doubt, one of the most serious infectious diseases of livestock, because it causes heavy economic losses to producers and it is transmissible to human beings. In the United States cattle and swine are most frequently attacked by the disease, but horses, sheep, goats, and other animals are susceptible. It occurs in all parts of the world where there is a well-developed livestock industry.

Cause.—The cause is a bacterial organism of the *Brucella* genus. There are three species: *Brucella abortus* in cattle, *B. suis* in swine, *B. melitensis* in goats. Cattle are susceptible to all three species, but only *B. abortus* causes typical symptoms and spreads from cow to cow. Hogs, too, may harbor all species, but *B. suis* is the only one of economic importance to the swine industry. Any of the three species may attack man, causing Brucellosis, an acute chronic disease also called undulant or Malta fever.

Brucella organisms may occur in almost any organ or tissue of an infected cow or heifer, but they are found most frequently in the udder and the uterus. They escape in large numbers from the infected uterus at the time of abortion or birth of the calf. Milk from infected cattle may contain these organisms. Bulls may harbor *Brucella* organisms in their testicles.

Method of Spread.—Susceptible animals become infected by eating contaminated feed, drinking contaminated milk or water, or having the germs come in contact with the skin. Human beings rarely or never contract the disease from infected persons. Contact with infected animals or animal products is the most potent source of human infection, but the use of infected foods, such as unpasteurized milk or cream from infected cows, may also produce the disease.

Symptoms.—In cattle the most characteristic symptom is abortion or premature birth. Shy breeding or sterility, mastitis or inflammation of the udder, decreased milk production, enlarged joints with or without lameness are other symptoms. But live calves are born to many infected cows and abortions occur among cows free of this disease. Consequently it is impossible to diagnose brucellosis accurately from symptoms alone.

Diagnosis.—The agglutination test made with blood serum is the routine method of diagnosing the disease.

Treatment.—No successful method of treating infected domestic animals has been found.

Losses.—This disease costs the dairy and beef industries of the United States at least from 50 to 100 million dollars annually. Infected cows, on the average, produce from 10 to 30 per cent less milk, have fewer live calves, and have more difficulty in breeding than noninfected cows.

Control and Eradication.—A national program of control and eradication, with federal and state veterinary officials cooperating, has been under way in the United States since 1934. In 1949 more than half a million herds containing nearly 6 million cows and heifers, or about 12 per cent of all female cattle of testing age, were tested. Slightly less than 4 per cent of them reacted. The percentage of reacting animals found is decreasing each year. Since this program began, thousands of herds have been freed of brucellosis by sending the reactors to the butcher.

cleaning and disinfecting the premises, and retesting at frequent intervals until no reactors are found. This procedure has been most successful in herds whose owners raise their replacements. Those who buy replacements usually reintroduce the disease sooner or later.

Vaccination against brucellosis has been widespread since Strain 19 *Brucella* vaccine became available. Since it has no curative value, this vaccine is recommended for use in brucellosis-free cattle only. Vaccinated cattle become positive reactors to the agglutination test. Heifers vaccinated at eight months of age or less usually lose their reactions after a few months, but vaccinated older heifers or cows may remain reactors for life. For this reason veterinarians do not usually recommend the use of vaccine in female cattle more than eight months old. Vaccinated heifers and cows ordinarily develop a marked, but not complete, resistance against the disease. Good results have followed vaccination of heifers in most herds wherein rigid sanitary precautions have been taken. But many owners apparently think vaccinates are completely protected and allow them to be severely exposed. Under such conditions a considerable number of vaccinates may contract brucellosis.

Prevention.—Since brucellosis is an infectious disease, a herd, a county, a state, or a country which is free of it can remain free by preventing the introduction of infection. This can be and is being done by the enforcement of quarantines. In areas where the disease is prevalent many owners of brucellosis-free herds vaccinate their heifers as an added precaution.

Anthrax.—One of the oldest diseases described in history, anthrax always has been one of the scourges of the livestock industry. Except for poultry, practically all farm animals as well as man are susceptible to this malady, but it affects most often cattle, sheep, horses, and goats. Swine also are sometimes affected. The disease is very widespread, occurring on every continent and in nearly every country.

Cause.—The cause of anthrax is a specific germ, *Bacillus anthracis*. This organism occurs in almost all tissues and organs of animals dying of the disease. Soil and pastures are contaminated by blood, dung, urine, and discharges from the nostrils and mouth of anthrax-infected animals. These germs form spores which, because of their resistance to drying, heat, and light, can live for years in the soil. Consequently, once infected, a pasture or a range may remain a constant source of danger indefinitely.

Domestic animals become infected by contact with diseased animals, grazing infected pastures, using infected pens or barns, eating infected feed, or drinking infected water. People contract anthrax by handling animals with the disease, especially by autopsying or skinning animals dead of anthrax, and by coming in contact with infected animal products, such as wool.

Symptoms.—The very acute form of the disease may kill cattle so quickly that almost no symptoms are seen. Acute cases live from a few hours to a few days and during this time have high fever, complete loss of appetite, marked depression, bloody diarrhea, and labored breathing. A foamy, blood-tinged discharge from the nostrils may appear shortly before death. The death rate among infected cattle is very high, but recoveries occur occasionally.

Diagnosis.—A positive diagnosis can be made

through finding anthrax organisms by a laboratory examination. Only veterinarians should hold autopsies and collect specimens from suspect cases, because of the great danger of untrained persons becoming infected from such practices.

Treatment.—If a very early diagnosis is made, the immediate use of large doses of antiserum may lead to recovery. Veterinarians report that some of the new antibiotics give good results. Any treatment must be used soon after symptoms appear.

Control and Prevention.—Vaccination produces marked resistance, but not complete immunity, against anthrax. All susceptible animals kept on known infected farms or ranches should be vaccinated before the anthrax season. If the disease appears despite vaccination, the animals should be shifted immediately to another range or pasture.

Since the carcass of an anthrax-infected animal is the most important source of infection, every such carcass should be completely burned without being opened. Any soil contaminated by discharges from sick or dead animals should be scraped up and thrown into a hot fire.

Farmers and ranchers whose premises are free of anthrax should never place on them grazing animals from infected pastures or ranges.

Blackleg.—This is an acute infectious disease occurring in nearly every cattle-producing country of the world. It affects young cattle principally; those less than from three to four months of age and more than two years old are seldom attacked. Well-bred cattle in good condition seem much more susceptible than common cattle, especially if the latter are not thrifty.

Cause.—The cause is *Clostridium chauvoei*, a very resistant organism which can live for many years in the soil.

Symptoms.—A hot painful swelling of the muscles of a fore or hind leg is usually the first symptom noticed. It crackles when rubbed, owing to the formation of gas under the skin. Severe lameness in the affected leg, loss of appetite, high temperature, and depression are other symptoms. Death usually occurs from 12 to 48 hours after appearance of symptoms.

Diagnosis.—Experienced veterinarians usually have little trouble in diagnosing blackleg. At autopsy they find that the muscles of the affected area are very dark and contain gas bubbles. A sweetish, disagreeable odor is said to be characteristic.

Control and Prevention.—No method of destroying blackleg germs in soil is available. Consequently, if young cattle are to be pastured on infected areas, owners must rely on vaccination, which has been found to be a reliable preventive. Calves should be vaccinated before the susceptible age, if they are to graze infected areas. Veterinarians recommend a second vaccination about a year later, if the soil of pastures is severely contaminated.

Seeding pastures with blackleg germs should be prevented by burning the carcasses of all cattle dying of the disease.

Piroplasmosis (Tick Fever).—In most of the tropical and subtropical countries of the world occurs this disease, which has attracted widespread attention, both because of its destructive nature and because it is the first disease proved to be spread by a parasite.

Cause.—Two species of parasites which attack the red blood cells of cattle, *Babesia bigemina*

and *B. argentina*, may cause tick fever. The natural method of spread from animal to animal is through tick bites. In the United States the common fever tick is *Boophilus annulatus*. Although this tick may attack other animals, such as horses or mules, it does not transmit this disease to them.

The life cycle of this tick is briefly as follows: Blood-engorged females drop off the host and lay eggs; eggs hatch into larvae; larvae attach themselves to cattle or other hosts and suck blood; after several days they molt and change to nymphs; nymphs suck blood, molt, and change to sexually mature ticks; mating occurs, after which the females engorge with blood and develop eggs; they drop off, thereby completing the life cycle. If a female has developed on an animal infected with tick fever, the larvae hatching from her eggs will transmit the disease to susceptible cattle.

Symptoms.—Young cattle are resistant to tick fever, but they gradually become susceptible as they grow older. Mature cattle develop symptoms suddenly from the seventh to the 14th day after infestation with disease-carrying ticks. They stop eating, become listless, develop fever, breathe rapidly, and lose weight. Milking cows have a marked decrease in production. Jaundice (yellow discoloration of the white of the eyes and of white skin) may occur. Dark-colored urine is a characteristic symptom which appears late in an attack. The disease runs a rapid course. The death rate is from 50 to 90 per cent in mature cattle. Symptoms are less severe and the recovery rate is much higher in cattle from 6 to 15 months old. Young calves develop few or no symptoms after exposure. Apparently recovered cases usually remain carriers throughout life.

Diagnosis.—Since some other diseases resemble tick fever, diagnosis is sometimes very difficult. The finding of fever ticks on sick or dead animals and the identification of the blood parasite by microscopic examination are the sheet anchors on which veterinarians depend.

Treatment.—Several drugs have given reasonably good results when used as treatments. Some of them are applied rather generally in areas where there is little prospect of destroying the disease. But veterinarians and cattlemen realize that eradication is by far the better procedure.

Eradication.—The disease can be eradicated by exterminating fever ticks. The U.S. Bureau of Animal Industry, in cooperation with the state livestock sanitary officials, began a program of eradication in 1906. Even before that, some 20 counties in North Carolina had been freed of the disease by extirpating fever ticks. The approved program consisted in dipping all cattle, horses, and mules in some tickicide, such as arsenic solution, at approximately two-week intervals. This prevents any female ticks from maturing and laying eggs. Dipping was continued until trained veterinarians and technicians no longer could find fever ticks.

Anaplasmosis.—This infectious disease of cattle often has been confused with tick fever. It occurs in most of the cattle-producing areas in tropical and subtropical regions and extends far into the temperate zones of some countries.

Cause.—The causative agent is *Anaplasma marginale*, a parasite of the red blood cells of cattle. Several species of ticks, including fever ticks, may act as carriers. Just as in tick fever, the offspring of female ticks developed on in-

fected cattle can transmit the disease. Other biting parasites, such as horseflies, may carry anaplasmosis.

Symptoms.—Symptoms in mature cattle include fever, fast pulse, rapid breathing, loss of appetite, rapid loss of weight. Marked jaundice is a prominent and usual symptom. Some affected animals are nervous and inclined to fight. The urine is usually normal in color. In the last stages sick cattle may be very anemic. From 20 to 60 per cent of affected mature cattle may die in from one to five days after symptoms appear. Animals which recover regain condition slowly. The yellow color of eyes and skin is noticeable for weeks after the acute attack has passed.

Symptoms are less acute and marked in yearlings and are scarcely noticeable in sucking calves.

Recovered animals usually remain carriers throughout their lives.

Diagnosis.—Veterinarians depend on the symptoms, findings at autopsy, and laboratory examination of blood for a definite diagnosis of the acute disease. No satisfactory method of detecting recovered cases which are carriers exists.

Treatment.—No very satisfactory treatment is known.

Control and Prevention.—Control and eradication is very difficult. Veterinarians neither can locate and remove the carrier cattle, as they do in eradicating tuberculosis, nor can exterminate the parasites which transmit the disease, as they do in extirpating tick fever. Great care should be exercised in dehorning, castrating, and bleeding cattle in known infected herds or areas, since anaplasmosis may be spread through carelessness in performing any of these operations. Owners of anaplasmosis-free herds should not add to them any cattle coming from infected herds or even from the vicinities in which such herds are found.

Nagana (Tsetse Fly Disease).—This infectious malady has prevented the development of any considerable cattle industry in a large part of central Africa. It is not known to occur in any other part of the world. The disease is caused by a blood parasite, *Trypanosoma brucei*, which is transmitted from infected to disease-free cattle by the tsetse.

Surra.—A blood parasite, *Trypanosoma evansi*, causes this infectious disease of cattle. It occurs in the tropical countries of Asia and the Philippines.

Countries free of this disease maintain quarantines to prevent its entrance. The necessity of such quarantines is proved by the fact that surra once was found in several cattle of a shipment held at quarantine in New York harbor for importation into the United States.

PARASITIC DISEASES

A large variety of parasites, including insects, worms, and protozoa, attack cattle.

Flies.—Four species of flies are found to spread disease among cattle.

Stableflies (*Stomoxys calcitrans*).—These important blood-sucking parasites of cattle closely resemble houseflies. They breed in manure or decomposing vegetable matter, such as straw. They can be controlled successfully by judicious use of DDT or some of the other new insecticides.

Horn Flies (*Haematobium irritans*).—In most sections of the United States these small blood-sucking flies are serious pests. Enormous swarms

may attack cattle, if conditions are favorable for their development. They breed primarily in cow manure. Some of the newer insecticides, such as DDT, are very effective against these parasites.

Screwworm Flies (*Cochliomyia americana*).—These serious parasites of domestic animals flourish in tropical and subtropical areas. They are destroyed by the winter cold of the cooler temperate zone so that, even when they invade such areas, they do not become permanently established.

The mature female fly lays eggs on or near wounds or bloody areas. These hatch into larvae or screwworms, which develop in the flesh. They produce serious injury, kill many untreated animals, and are especially destructive to newborn calves, lambs, and pigs.

Fly repellents, such as Smear 62, which was developed by the federal Bureau of Entomology and Plant Quarantine, are rather effective in preventing infestation of screwworms. If the worms are present, they all should be removed and the repellent should be applied to prevent further infestation.

Warble Flies (*Hypoderma lineatum* and *H. bovis*).—These are of considerable economic importance because of the damage done to both meat and leather. Mature female warble flies attach their eggs to hairs. When these hatch, the young larvae burrow through the skin, migrate through the animal's body, and finally become located under the skin of the back. After several weeks of development they emerge, drop to the ground, where they pupate. Here they undergo further development and finally emerge as mature flies.

The larvae may be killed by spraying, washing, or dipping infested cattle in rotenone solution. Warble flies can be eradicated, if all cattle in an area are treated so that no larvae mature.

Lice.—Three species of lice are rather commonly found on cattle in the United States. Two of these are bloodsuckers and may do serious harm. Many insecticides are fairly effective against these parasites, if they are properly used as dips or sprays.

Mange, Itch, or Scab Mites.—Four species of mites occur on cattle in the United States causing mange, itch, or scab. The part of the skin affected varies according to the species of mite present. If neglected and left untreated, scab may spread through a herd, affecting most of the cattle and causing serious damage.

Symptoms, diagnosis, treatment:—Symptoms are scratching, shedding of hair, thickening of skin. Definite diagnoses are made by finding the mites. Solutions containing lime-sulphur, nicotine, benzene hexachloride, or crude petroleum are used successfully in treating infested cattle.

Ticks.—Nearly a dozen species of ticks have been reported as parasites of cattle in the United States. Since all these are bloodsuckers, they do serious harm if present in considerable numbers. The tickicides (see TICK FEVER) will destroy most of these species, but unfortunately many of them have life cycles unfavorable to eradication.

Worms.—In cattle these are distinguished by the organs which they invade.

Roundworms of Stomach and Intestines.—These include at least three rather common stomach worms (*Haemonchus contortus* or the twisted wire worm, *H. similis*, *Ostertagia ostertagi*) and half a dozen or more intestinal worms (*Bunostomum phlebotomum* or the cattle hookworm, at

least three cooperids or hair worms, *Neoascaris vitulorum* or the large roundworm, *Oesophagostomum radiatum* or the nodular worm). In nearly every case of parasitism occurring under natural conditions, more than one of these species are present. Most of these parasites have somewhat similar life cycles. Mature females lay eggs which are evacuated with the droppings and which then hatch. The larvae must molt before they become infective. Following molting, which requires only a few days, they encyst on grass or other vegetation and develop into mature worms, if swallowed by a susceptible animal.

Symptoms: Weanling calves and yearlings are most often attacked; mature cattle, only occasionally. Symptoms include unthriftiness, failure to grow and to gain weight, loss of weight, rough hair coat, chronic diarrhea, bottle jaw (a soft painless swelling in the throat region). Veterinarians make a definite diagnosis by holding an autopsy or by finding worm eggs in the droppings through a microscopic examination.

Treatment: Phenothiazine is very effective as a treatment against many of these parasites. Other drugs, such as tetrachlorethylene, have been used.

Control: Fortunately, cattle infested with small numbers of stomach and intestinal worms usually develop a fairly effective resistance against further infestation. Control measures include rotation of pastures, allowing them to be idle, and avoidance of overgrazing.

Lungworms (*Dictyocaulus viviparus*).—These parasites, which cause husk or lungworm disease, live in the trachea and bronchial tubes. Their life history is similar to that of the roundworms of the stomach and intestines, but their larvae are destroyed more easily by drying. Consequently they are not serious parasites, if the pastures or ranges are dry.

Symptoms: These are seen most often in calves and yearlings. They include coughing, rapid breathing, unthriftiness, failure to gain properly.

Treatment: No successful medicinal treatment has been found.

Control: Since the larvae are short-lived, a rest period from six weeks to three months will usually free a pasture of infestation.

Liver Flukes (*Fasciola hepatica*).—The most serious of the flatworms infesting cattle, these parasites are shaped somewhat like a cherry leaf and in the mature form are nearly an inch long. They live in the bile ducts and gall bladder and pass their eggs into the intestines along with the bile. After leaving the body in the dung, eggs hatch if they are moist and warm. The larvae attack certain species of snails, burrow into them, and undergo further development and multiplication. Finally they emerge from the snail and encyst on grass or even on the surface of the water. When these cysts are swallowed by cattle, the young parasite burrows through the wall of the intestine and enters the liver.

Symptoms:—Flukes attack cattle of all ages. Many cattle heavily infested with flukes show no symptoms whatever. But poorly nourished cattle or those infested with other parasites may become unthrifty, lose weight, and have diarrhea and anemia, if large numbers of flukes are present. Diagnosis is made by finding fluke eggs in the droppings or by post-mortem examination.

Treatment:—Hexochlorethane is a satisfactory treatment.

Control.—Liver flukes may be controlled by destroying the snail hosts on pastures and by repeated treatment of cattle.

Protozoa.—The principal protozoa attacking cattle are the Coccidia, microscopic-sized parasites which develop in the intestines and induce the disease known as coccidiosis. In the United States at least six or eight species occur commonly in cattle. They are very widespread, occurring in most herds except those grazing in very dry areas. Coccidia are usually host specific, that is, neither those attacking cattle will attack other species of animals nor are cattle susceptible to those which cause coccidiosis in other animals, such as chickens, sheep, dogs.

These parasites, multiplying within the cells of the wall of the intestine, have a complex life cycle. But they finally develop oöcysts, a form which must leave the body and undergo changes (sporulation) in contact with the air before further development in the host animal can occur.

Symptoms.—Cattle of all ages are susceptible to coccidiosis, unless they have been previously exposed. They become infected by swallowing sporulated oöcysts. Symptoms vary according to the species present and the number of oöcysts ingested. They range from a very mild diarrhea, lasting only a day or two, to loss of appetite, fever, bloody persistent diarrhea, and death. Mortality is very high among heavily infested young calves.

Treatment.—Some success has resulted from treatment with several of the sulfa drugs.

Control.—Prevention is largely a problem of management. If good sanitary practices are followed, calves on most farms are exposed to only small numbers of coccidia, but these result in a marked resistance of the animals to the disease. Calves raised on open ranges, especially in dry sections, may not be so exposed and may remain completely susceptible. Concentration of such animals in infested feed lots should be avoided, otherwise explosive outbreaks of coccidiosis may occur.

CATTLEYA. See ORCHID.

CATULLUS, Gaius Valerius, Roman poet: b. Verona 87 or 84 B.C.; d. probably 54 B.C. He is deemed by some to be Rome's greatest lyric poet, by others to be second only to Horace. His family seems to have had social standing and at least moderate means; for his father often entertained Julius Caesar, and the poet apparently never had to earn his living. While still a youth he could go to Rome and there complete an excellent education. It was in the expensive metropolis, too, that he chiefly resided, although his native town and his villa at Sirmio (Sermione) on the Lake Garda, and another not far from fashionable Tivoli, would from time to time claim his presence. His one trip abroad may have been a financial venture, but it was perhaps mainly to visit the storied cities of the East that he joined the staff of Memmius, who governed Bithynia in 57-56 B.C. The provincials proved too poor to yield profit even to an unscrupulous official, much less to one of his suite, and Catullus vented his spleen in lampoons that contrast strikingly with

the eulogies of the other great contemporary poet, Lucretius, who revered Memmius as his patron. Catullus' trip did, however, allow a visit to the grave in the Troas (Troad), of his only brother. His expressions of inconsolable grief are among the most affecting in Latin literature. In lively contrast are the two inimitable poems that voice his joy at returning home. The year's absence had at least quenched the last embers of his passion for Lesbia, who had been for some years the curse and inspiring genius of his life. According to the generally accepted theory, Lesbia is his pseudonym for perhaps the most remarkable woman of the day, Clodia, the sister of Publius Clodius Pulcher. She was at least 7, and perhaps 11, years older than Catullus, and in 61 B.C., when he fell in love with her, was the wife of Metellus Celer, a consul-elect. Apparently even Cicero did not wholly escape the fascination of this beautiful though utterly dissolute queen of the Roman "fast set." The course of the poet's liaison may be traced in a series of poems that expose his inmost feelings with a power and vividness that critics deem almost unequaled. To the period of difficult courtship belong madly passionate lyrics and the dainty "sparrow-songs." Next a lovers' quarrel and reconciliation engage our sympathies. Soon, however, the poet's faith in Lesbia's fidelity wanes, and with it all purer love, although his passion grows only the wilder and more intense. The poems in which he assails successive rivals, beginning with the brilliant but disreputable Caelius Rufus, are marvels of invective. It is only after his return from Bithynia that Catullus seems fully to appreciate the hopeless infamy of his former mistress, when he sends a scathing reply apparently to a proffer of reconciliation. While it is this cycle of love poems that has immortalized Catullus, he wrote admirably on other subjects. In spite of a life of pleasure, he had energy to study thoroughly the early Greek lyric poets, and especially the technical achievements of the Alexandrine school, which began now to have great influence upon Latin poetry. Although some direct translations from the Greek also attest his interest in these models, Catullus remained peculiarly independent. No matter how much his lyrics may show the results of his studies, they were primarily an outlet for feelings that compelled utterance, and not, like Horace's odes, a purely intellectual performance. He is less original in some of his long poems. The longest is an epithalamium, in Alexandrine style, upon the wedding of Peleus and Thetis, introducing also the story of Theseus and Ariadne. While Catullus' work in mythological epic no doubt made that of later writers, including Virgil, easier, his daring dithyrambic poem on Attis has remained unique. On the other hand, his epithalamia are the forerunners of others in Latin literature, as also of the marriage poems of Spenser, Jonson and Herrick. Horace also often appears in his odes the older poet's debtor, though in artistic form his superior. In epigram Martial (Marcus Valerius Martialis) is ready to concede the palm to Catullus as well as Domitius Marsus, though himself the acknowledged master of that form. Furthermore, in the leading elegiac writers, Tibullus, Propertius and Ovid, we clearly see their obligations to Catullus and often read his praises. He enjoyed, too, the admiration of contemporary writers, and not alone those of

his own school of poetry, like Gaius Calvus and Gaius Helvius Cinna; for the historian Cornelius Nepos seems to have started him auspiciously in his literary career. To him he gratefully dedicated a partial edition of his poems. Other famous Romans who receive kindly mention are Gaius Asinius Pollio, Quintus Hortensius Hortalus, and Marcus Tullius Cicero. Gaius Julius Caesar, however, is attacked with a fearlessness as amazing as the language is shocking. But in judging Catullus' obscenities, his liaison with Clodia, and other even less creditable relations, moderns are charitable in proportion to their knowledge of the standards of that age. Even the most severe are won to sympathy, if not affection, by happier glimpses of the poet's character. In an age of insincerity every word of his rings true. His gentler side appears in his verses on babies, flowers, and the beauties of nature, in his affection for his brother and his friends, and even in the better aspects of his love for Lesbia.

Besides the English poets already mentioned, Matthew Prior, Thomas Gray, Lord Byron, Walter Savage Landor, and Alfred, Lord Tennyson, have shown special admiration of Catullus. Among numerous excellent editions of the poet, the text edition of Robinson Ellis (1904) may be named. Besides the *Commentary on Catullus* by Ellis (1876; 2d ed. 1889), the English reader has the poetical translations of Theodore Martin (1875), those in prose by Francis W. Cornish (1913), and perhaps best of all, Hugh Vibart Macnaghten's *The Story of Catullus* (London 1899).

WALTON BROOKS McDANIEL,
Professor Emeritus of Latin, University of Pennsylvania.

CATULLUS, kătŭ-lŭs, the name of an ancient Roman family of the Lutatian gens.

GAIVS LUTATIUS CATULLUS was the admiral who defeated the Carthaginians near the Aegadian (Aegates) Isles off the Sicilian coast in 241 B.C., thus closing the First Punic War.

QUINTUS LUTATIUS CATULLUS (152?-87 B.C.) was a Roman general, historian, and poet. He was consul in 102 B.C. with Gaius Marius, and in the following year was proconsul. During his proconsulship he, with Marius, defeated the Cimbri near Vercellae (now Vercelli) in northern Italy. As one of the aristocratic party and a partisan of Lucius Cornelius Sulla, he was proscribed by Marius and committed suicide. With the exception of two erotic epigrams, nothing of his writing has survived.

QUINTUS LUTATIUS CATULLUS (d. about 60 B.C.), son of the preceding, was consul in 78 B.C. and censor in the next year. He quelled the revolutionary uprising of Marcus Aemilius Lepidus, his colleague in the consulship, and assisted Marcus Tullius Cicero in suppressing the Catilinarian conspiracy in 63 B.C.

CAUCA, kou'kă, one of the 15 departments of Colombia, South America, bordering on the Pacific Ocean; area 11,657 square miles. Originally a separate sovereign state, its sovereign rights were abolished in 1886, although some privileges, such as issuing postage stamps, were retained until 1904. Two of the ranges of the Andes Mountains, the Cordillera Occidental and the Cordillera Central, cross the department from north to south. The Cauca, Patia, and Caquetá rivers rise within its territory. No railroads exist

in Cauca, and the chief outlet is by way of the Cauca Valley to Cali, where a railroad and a highway run to the seaport of Bonaventura. Airline service between major points is frequent. The capital is Popayán (q.v.). Most of the population is in the uplands and valleys. Coffee, grown on the mountain slopes, is one of the most important industries, and tobacco, sugarcane, cacao, rice, figue, cotton, and bananas are also raised, as well as cattle. The natural resources include gold, platinum (at Belalcázar and Timbiquí), copper (Santander), silver, marble, sulphur, coal, and petroleum. Pop. (est. 1950) 454,200.

CAUCA, river, Colombia, South America, main tributary of the Magdalena River, rises in the Andes in Cordillera Central south of Popayán, and flows about 600 miles north, passing through a valley 150 miles long and 20 wide at an elevation of nearly 3,000 feet, between the high cordilleras. It descends into the left arm of the Magdalena River (Brazo de Loba) where it runs into rain forests and swamps. It is only partly navigable for small craft on its lower courses. The valley of the Cauca, where a tropical climate with abundant rainfall produces a great variety of agricultural products, is considered one of the most beautiful in the world, while it is certainly one of the most fertile. It also has rich gold placer mines.

CAUCASIAN RACE, kô-kă'shăn, commonly called the "white race," and sometimes the "Europid race," is generally considered one of the primary varieties of modern man. The designation "Caucasian" was proposed in 1775 by Johann Friedrich Blumenbach (q.v.) on the dubious theory that this racial group arose in the Caucasus region. In general, the Caucasian or Caucasoid race inhabits Europe, western Asia, and North Africa. Certain white groups (such as Finns, Hungarians, and Turks), are sometimes excluded as being too largely Mongoloid in origin. The European Caucasoids are subdivided into the Nordic, Alpine, and Mediterranean subraces, the Mediterranean grading into the stocks of western Asia, such as the Arabian and Indo-Afghan.

The Caucasoids tend to have wavy head hair, varying in color from yellow to dark brown and even black. Complexion ranges from white in Europeans to dark brown in some Indo-Dravidians. The nose is commonly narrow and prominent and the profile straight or orthognathic. See also ANTHROPOLOGY; RACES, NATURE AND ORIGINS of; and bibliographies of these articles.

JAMES H. MCGREGOR,
Professor Emeritus of Zoology, Columbia University.

CAUCASUS, kô'kă-sŭs, a huge peninsula in the Soviet Union, approximately 80,000 square miles in area, lying between the Black and the Caspian seas, and connecting the European Union of Soviet Socialist Republics with Turkey and Iran. Though the vast Kuban plain, one of the richest grain-growing areas of the Soviet Union, is sometimes considered part of the Caucasus, the actual geological and ethnographical northern boundary of the peninsula is formed by the Kuban and Terek rivers, dividing this plain from the Greater Caucasus Mountains, the highest in Europe. Below this great mountain chain is the Transcaucasian Valley, where most of the population of the Caucasus resides. On the south

of the peninsula are the Lesser Caucasus Mountains, bordering on Turkey and Iran. The climate of the Caucasus is subtropical, with hot summers and mild winters. Moist winds from the Black Sea make the west Caucasian coast a "Soviet California," ideally suited for the growing of fruit and other subtropical crops. In contrast, dry winds from the central Asian desert convert the east Caucasian coastal plain into desert and semi-desert, where agriculture is practiced mainly on irrigated land with cotton the chief crop.

Both mountain chains are abundant in minerals and provide pastures for large-scale raising of cattle and sheep. Resorts are numerous both on the Black Sea coast and in the Greater Caucasus Mountains. The rivers of the Caucasus are mostly fast-flowing mountain streams unsuitable for navigation, but with great potentialities for hydro-electric power, which is beginning to be exploited. The two largest rivers drain the Transcaucasian Valley: the Rion flowing into the Black Sea, and the Kura flowing into the Caspian. Transportation is poorly developed, most roads in the mountains being mere trails. Oxen, camels, mules, and donkeys still remain the chief means of short haul transport. Aside from well-developed coastal shipping, the peninsula's long-distance transportation depends tremendously on three railways: the old Caucasian line running from the Ukraine to Makhachkala on the north Caspian coast, thence down this coast to Baku, and across the Transcaucasian Valley to Batum; a recent line from Baku along the Iranian and Turkish border to Tbilisi (old Tiflis) via Yerevan; and the new Black Sea railway running up the west seacoast from Batum to the Ukraine. Airways link major Caucasian cities and resorts with all regions of the USSR.

Because of its isolated mountain valleys and long history as a crossroads between Europe and Asia, the Caucasus is a land of many races. There are 30 major nationalities, of which the largest numerically are the Azerbaidzhani, Georgians, Armenians, Dagestani, Ossetians, Kabardinians, and Russians. Because of this racial diversity, the peninsula is divided into 18 major administrative regions, the most important being the Azerbaidzhan, Armenian, and Georgian Soviet Socialist republics; and the Dagestan, Kabardinian, and North Ossetian Autonomous Soviet Socialist republics; Krasnodar and Stavropol territories, and Grozny Region of the Russian Soviet Federated Socialist Republic. The largest cities are Baku, Tbilisi, Yerevan, and Grozny.

The Caucasus produces over half of all Soviet petroleum; therefore oil mining and refining is the main Caucasian industry, with the greatest oil fields at Baku, Maikop, and Grozny. The manganese mines in Georgia are the largest in the world. Other important mineral products are uranium, coal from Georgia, copper from Armenia, iron ore and alunite from Azerbaidzhan, and cement rock, molybdenum, and natural gas from the northern slope of the Greater Caucasus Mountains. There are also extensive industries processing raw materials, with the largest center at Tbilisi. Agriculture concentrates on subtropical crops, the Caucasus importing part of its grain for food from the Kuban plain. The Caucasus is the second largest cotton-growing region of the USSR, yielding only to central Asia. Other major crops include grapes, tobacco, fruit, silk, and tea, all of which are exported to European Russia. Caucasian wines are famous throughout

the USSR. Wool and leather are produced on a large scale. Much fish is caught along the coasts, and valuable timber is cut in the mountain foothills.

Because of its strategic location on east-west trade routes, the Caucasus has had a stormy history and many wars. Mongols, Turks, Persians, Tatars, and empires long forgotten once ruled and fought over the peninsula. Czarist Russia conquered the Caucasus with much difficulty during the 19th century, and Russian Communists had to reconquer it in 1920. The result is a land of contrasts, a blend of Oriental and European civilizations. Pop. (1950) approximately 11,000,000.

ELLSWORTH RAYMOND,

Assistant Professor of Soviet Government and Economics, New York University.

CAUCASUS MOUNTAINS, a lofty range which stretches in a long diagonal, a little south of east between European Russia and Asiatic Georgia. The length in a straight line is about 700 miles, which various windings increase to over 900 miles. The width varies from 30 to 130 miles. Westward the mountain mass extends toward the Crimea, nearly separating the Black and Azov seas, while eastward it projects for about 50 miles into the Caspian in the Apsheron Peninsula. No fewer than 20 summits rise higher than Mont Blanc. Elbrus of the cloven crest, towering 18,481 feet, is the loftiest mountain in Europe, while at least two others exceed 17,000 feet. Among numerous peaks which have challenged mountain climbers, Ushba (15,400 feet) presents more difficult rock work than the Matterhorn. Along the northern slopes of the Caucasus, Jurassic and Cretaceous sediments predominate, but dip toward the Russian plains beneath more recent strata. Much folding took place during the Permian and Jurassic periods and continued into the Miocene. The central ranges present a core of crystalline rocks amid Paleozoic and Jurassic schists and gneisses. This crustal upheaval was accompanied by much volcanic activity and Quaternary gravels are covered by recent lava flows. Elbrus is thought to be a dead volcano, as is also the dark cone of Kazbek rising 16,541 feet, while mud volcanoes are still active in the Apsheron region. Northward the snow line ranges from 9,000 to 10,000 feet, while on the sunnier, southern heights it rises to about 11,000. More than 900 glaciers have been enumerated, but they do not descend to such relatively low levels as those in the Alps. There are few lakes, but rather a rocky chaos of beetling crags faced with sheer precipices. Hence the scenery, though impressive, is wild and gloomy rather than beautiful.

The foothills along the Black Sea, however, present views as lovely as those of Italy. The mountain slopes, particularly toward the south, are clothed with dense forests. Here is the habitat of Circassian walnut. Flowering shrubs and plants are numerous. Among characteristic wild life are the chamois and the goat-like turr. The red stag of the Caucasus has long attracted hunters, while the western wilderness was one of the last strongholds of the European bison. The Caucasus have reared a well-nigh impassable barrier between that sector of Europe and Asia. Unlike the Alps, they present a nearly unbroken wall. About midway from east to west the chain is pierced by one of the most famous of mountain passes, the Daryal, which has been excavated by

the Terek River flowing northeastward into the Caspian. Here sheer cliffs rising 6,000 feet leave barely room for the road. A few loftier passes are usually choked by snow. Hence, conquering armies approaching from Asia have been forced to outflank the mountains where they encroach upon the Caspian. In this narrow passage Alexander the Great (r. 336–323 B.C.) built a wall that was called the Gate of Iron. Even the invincible raiders of Genghiz Khan could force this defense only by stratagem.

The Caucasus are rich in minerals which include silver, copper, and less common ores. There is some quicksilver, sulphur, iron, and a great deal of coal. Near Kutaisi are to be found the world's richest deposits of manganese. Even more important are the oil wells of Baku, famous for centuries and still a leading petroleum field.

The Caucasus Mountains were prominent in Greek legend. Jason voyaged there seeking the golden fleece, and it was against their rocky flanks that Zeus chained Prometheus. Greek adventurers thought their snow-capped summits the loftiest in the world. They have always provided refuge for persecuted minorities. To their inaccessible valleys fled deserters from every invading army from the Assyrians to the Crusaders and the Turks. Prominent among the present mixture of races are Georgians, Abkhazians, Mingrelians, and Circassians. It was here that early investigators thought they had located the perfect type of the white race which is still called Caucasian. Among the mountain fastnesses villages of various nationalities rise tier above tier seeming to blend with the drab background. Two full centuries of pressure elapsed before the hardy inhabitants accepted the Russian yoke. During World War II, German outposts penetrated the region and for a brief time planted the swastika upon the summit of Elbrus.

FERDINAND C. LANE,
Author of "The Story of Mountains."

CAUCHON, kō-shōn', Pierre, French bishop: b. near Reims, France, in the latter half of the 14th century; d. Dec. 18, 1442. He is first heard of as rector of the University of Paris; in 1413 he joined the Burgundian party and was exiled by the Parlement. When his party returned, victorious, Philip the Good, duke of Burgundy, gave him a canonry at Beauvais and eventually had him made bishop in 1420. He was so unpopular that he had to leave Beauvais, and in 1429 he joined the English court, assisting at the coronation of Henry VI in Paris on Dec. 17, 1431. On May 24, 1430, Joan of Arc had been taken prisoner at Compiègne, in his diocese, and Cauchon claimed the right of judging her. He followed her to Rouen, where his conduct of the trial was particularly odious. After condemning her to life imprisonment, he changed his decision, declaring her a relapsed heretic, and handed her over to the secular arm on May 30, 1431. He could not return to Beauvais, and the king of England granted him the bishopric of Lisieux in 1432. In such execration was he held that after his death Pope Callistus IV had his body exhumed and thrown into the common sewer.

CAUCHY, kō-shē', Augustin (Louis), French mathematician; b. Paris, France, Aug. 21, 1789; d. Sceaux, May 23, 1857. Entering the Polytechnic School in 1805, he distinguished himself by the solution of difficult problems. In 1816

he won the Grand Prix of the Academy of Sciences for his paper on wave propagation. Qualifying as a civil engineer, poor health turned his attention to science, and he became a teacher. His political bias for the legitimate monarchy and the Roman Catholic faith sent him into exile in 1830 when he refused to take the oath required by Louis Philippe. Charles X made him a baron. He returned to Paris in 1837, and from 1848, when he was exempted from taking the oath under Napoleon III, until his death he was professor of mathematical astronomy at the Sorbonne. He published numerous works on mathematics, especially calculus. He invented the calculus of residues; the theory of functions of a complex variable; developed the wave theory in optics, and worked on the theory of stress in elasticity, as well as many other problems. The Academy of Sciences published his *Oeuvres complètes d'Augustin Cauchy*, in 27 volumes (1882–1901).

CAUCUS. The history of the word "caucus" has been traced to several sources, the most acceptable of which is the Algonquin *kaw-kaw-wous*, to consult. Other lines of descent go back to "caulkers," secret gatherings of dock workers in Boston, or to a Latin word for "cup"—hence a convivial gathering. A caucus may be (1) a town or community meeting to decide upon local policies; (2) a gathering of members of a party or faction to nominate candidates for elective office or to select delegates to a nominating convention; (3) a conference among party members in a legislative body to choose their leaders or to draw up a plan to promote or to oppose a specific legislative program. The Russian historian Moisei Y. Ostrogorski quoted John Adams as having said: "Our revolution was effected by caucuses. The federal constitution was framed by caucuses, and the federal administrations, for twenty years, have been supported or subverted by caucuses."

The beginning of the caucus has been ascribed by the Anglo-American historian William Gordon to the political leadership of the elder Samuel Adams during the second quarter of the 18th century (about 1735). The Caucus Club in Boston, according to John Adams' diary notation in February 1763, was regularly choosing assessors, collectors, and representatives before they were chosen in the town meeting; and the members of the caucus sent "committees to wait on the merchants' club, and to propose and join in the choice of men and measures." Samuel Adams, the Revolutionary patriot, and his father Samuel were credited with promoting the caucus for deciding upon nominations which later received formal approval in town meetings. Local committees served to correspond with committees in Massachusetts and in other colonies until a whole network of committees of correspondence operated to crystallize opinion against England. Such arrangements suggest party organization as effective and as widespread as were the later Whig and Democratic party committees. It is a logical sequence from caucus to committees of correspondence to a Continental Congress. Opinions from small groups moved into higher bodies until united action came from men who had the machinery to assert and to prove the independence of the United States. The caucus was the town device for decision and action.

The Conference.—Side by side with town caucuses there developed conferences or conventions to decide on persons to be supported in county or

district elections and later for state offices or for federal electors. The practice of thus delegating the selection of officers or slates of favored candidates was common in the counties early in the 19th century. The earliest caucus nomination for state governors was the "recommending" of candidates by rival parties in Rhode Island and Pennsylvania in 1790. In Pennsylvania the nominating body was something more than a legislative caucus (members of a given party sitting in the legislature), for it contained both legislators and delegates to the state constitutional convention. But in 1793 in that state the nominations were entirely by the party members in the legislature. Thereafter, according to Ostrogorski, the *legislative caucus* to nominate a candidate for governor was used in all states. The *congressional caucus* on the national level performed a similar service in naming party candidates for president and vice president from 1800 to 1824. Since some districts were not represented in a party caucus of legislative members at the state capital, local party leaders visited the city to sit in with the legislative caucus. This constituted the *mixed caucus*, that is, one made up of legislators and nonlegislators.

Party Discipline.—For effective support in the subsequent campaign the participants in a caucus agree in advance to support those persons selected by a majority. Party solidarity has always rested on loyal support for a party decision or for a party nomination. The nominating process has followed several patterns: (1) self-nomination; (2) caucus nomination; (3) selection through corresponding committees, who in turn presented the lists to their local caucuses; (4) conventions whose delegates were selected in a "primary" meeting of local voters; (5) legislative caucus; (6) mixed caucus; (7) mixed convention; (8) pure convention; (9) the direct primary; (10) a combination of primary and convention. See also CONVENTION, POLITICAL; PRIMARY, DIRECT.

Correspondence Men.—When the Constitution was ratified (1788), conventions of both Federalists and Antifederalists were held in Pennsylvania to prepare lists of eight persons for congressman at large for the 1st Congress under the new form of government. These conventions used methods borrowed from certain religious organizations; the Presbyterian procedure for the selection of delegates to a general synod (copied by the Federalists), and the Friends' custom of using nominating committees (copied by the Antifederalists). It may be remarked that the era of 1787 to 1793 was notable for conventions in France and in the United States. Many enthusiasts for democracy, especially in Pennsylvania, admired the democratic flowering in the early days of the French Revolution. But conventions were expensive and inconvenient for delegates who had to travel long distances. Hence, the area having the greatest number of conventions (Pennsylvania) gave way to a competing nominating procedure, the correspondence men. These industrious individuals framed lists of favored candidates through a system of exchanges. The struggle between the conference men, who wanted the convention system in order to reach a more democratic determination of the will of the common people, and the correspondence men was bound to be resolved in the most economical way. Briefly, the convention method lost favor. But oddly enough, the opposition also gave way before the rising legislative caucus, itself an inexpensive

and rather natural successor to the two previous procedures.

The Iron Law of Oligarchy.—The concept of a "wheel within a wheel" fits party politics as well as other social relationships. The tendency toward the formation of small dominating groups at the center of a social organism is seen in (1) the town caucus for nominating candidates; (2) the committees of correspondence; (3) district or state conventions; and (4) various forms of legislative caucus. These developments always point up the leadership by aggressive, industrious men who have a strong penchant for politics; who have leisure; who have wealth to correspond, to travel, and to entertain socially; who represent local points of view; and who learn the art of compromise throughout the state or nation. Parties grow, succeed, feed on success, and solidify into permanent organs. There is an aristocracy of talent, of virtue, of intellect, of wealth, of influence always directed toward obtaining and exercising power. Transitions of whatever sort reflect either concessions to demand for reform or adjustment to convenient techniques. In the new arrangement a dominating clique or organization will appear. The cry to be free from the tyranny of "King Caucus" is repeated until some mighty champion leads his people out of bondage. The emancipation is achieved by the efforts of a new political machine.

Congressional Caucus.—A peculiarity of the congressional caucus in the first quarter of the 19th century was its periodic selection of a secretary of state to succeed to the presidency—James Madison to follow Thomas Jefferson, to be followed by James Monroe, and Monroe to be followed by John Quincy Adams. "The Virginia dynasty" was broken by the elevation of Adams; and this itself came years after New York leaders in the Democratic-Republican Party of that day had pleaded for state sovereignty as against the centralized power of the Virginia clique. One of the sponsors of reform of the caucus was Henry Clay, who rose to the position of secretary of state through his support for Adams in the House contest among Andrew Jackson and Adams, and Crawford. William H. Crawford was the last man to be selected in a congressional caucus (1824). As secretary of the treasury, Crawford had conceived of the plan to use a vast network of revenue collectors as a political machine. His nomination took place before hostile spectators who had gathered to watch a caucus attended by only one third of the party members in Congress. By 1828, "King Caucus" had abdicated.

Influence on Electoral Procedures.—The influence of the caucus upon the American constitutional system may be traced briefly. The Constitution provided for the election within each state of presidential electors who were presumed to act independently at their respective state capitals in voting for president, each elector casting two votes. The candidate receiving the largest vote was to become president and the next highest to become vice president. Political parties were active while George Washington was president, but only at the prospect of his retirement did the parties view the presidential office with deep interest. Alexander Hamilton as a Federalist had little regard for John Adams, for eight years the vice president under Washington. The Federalist electors were advised by Hamilton to vote for both Adams and Charles C. Pinckney, but Hamil-

ton's hope that a few would not vote for the rather unpopular Adams—and thereby allow Pinckney to win the presidency—was not realized. As a matter of fact, the Democratic-Republican Jefferson scored a higher vote than Pinckney and thus became vice president. In the election of 1800 both parties held caucuses in secret and planned their strategy. The Democratic-Republicans won the electoral vote and proceeded to vote 73 electors for Jefferson and 73 for Aaron Burr, intending the presidency and vice presidency respectively. But since there was a tie, the presidential electoral vote was ineffective, and the House of Representatives proceeded to ballot for president between Jefferson and Burr. After many ballots and great uncertainty, Hamilton's influence was thrown to Jefferson, who thus became president by the help of the leader of the opposite party. This imbroglio led to the adoption of the 12th Amendment which provided that electors should vote separately for president and vice president.

Another effect of the caucus was the great emphasis in each state toward the general ticket for election of presidential electors as opposed to the district system. In the latter plan, each party could win a few electors, showing a reasonably proportionate strength among the voters in a given state. But state leaders were tempted to sweep the electoral slate on a general ticket, especially in large, pivotal states. The caucus encouraged the general ticket, and the general ticket produced a strongly dominant caucus. For more than a century, the general ticket has been used in all states, with the exception of Michigan in 1892. Candidates come from great pivotal states, and the concentration of campaigning falls to states with tremendous electoral strength.

Another lesson from the era of caucus government relates to a one-party situation. The argument that the caucus was necessary for unity against the political enemy lost its force when the Democratic-Republican Party had no opposition after the disintegration of the Federalist Party following the election of 1816. Furthermore, the ruling oligarchy of a one-party nation fell apart. One faction was tempted to control the caucus, and the competing faction sharply challenged the power of the caucus. When the caucus was discredited, the convention came into more general use for nominations in county, state, and nation.

Legislative Caucus.—The reasons for the legislative caucus, both state and national, were numerous: (1) It was convenient, since the legislators were at the capital for official sessions. (2) Legislators were familiar with broad problems of government. (3) They could select wisely those persons most competent to hold executive office. (4) They were official leaders in their own communities and thus enjoyed the confidence of their people.

The reasons for the persistent outcry against the legislative caucus were also numerous: (1) Some people at the base of the political system resented the assertion of power by a small clique in either legislature or Congress. (2) The Constitution forbade officeholders in the national government to serve as presidential electors, and yet the members of Congress in a party caucus took upon themselves the power to name the party candidate, thereby indirectly assuming a power withheld by the Constitution. (3) By this device the president owed his office to his party in

Congress, thus removing one of the principal checks within our constitutional system. (4) If a district was not represented in the legislative body it did not have a voice in the legislative caucus. (5) If that party was in a minority in the legislature there were relatively few districts expressing a voice through such a caucus. There was the additional taint of patronage in the hands of the executive in dealing with legislators.

Party organization in Congress employs the caucus for purposes that fall under two important heads: (1) to decide on party positions, such as floor leader and whip, to determine committee assignments, and to enable the majority party to choose a speaker in the House or a president pro tempore in the Senate; (2) to deliberate on proposed legislative measures in terms of party attitudes toward specific matters. Determination of policy is in the hands of organs recognized by the Legislative Reorganization Act of 1946 as the party conference and the party policy committee. Each party has such organs, designated as the Majority and Minority Policy committees. These are officially recognized for coordinating purposes and have their appropriations for operation with a staff of a dozen employees. The policy committees are elected by the party conference, the entire party membership in that branch acting in caucus.

Historians have rightly interpreted the democratizing forces of westward expansion as accounting for the emergence of Jacksonian egalitarianism. Frequent rotation in office, extension of the suffrage, numerous elections, exciting conventions, spoils politics, and a tremendous faith in state programs at the expense of national power, all marked the era of Democratic politics, spelled with a large and small D. But the observer may note that when the convention supplanted the former congressional and legislative caucuses, there was a quick rise of the custom of nomination in "smoke-filled rooms," which is another way of recognizing the new caucus techniques in the new political setting. These were used for choosing delegates in each state and for the eventual selection of candidates for president and vice president. The caucus moved from the halls of Congress to the key rooms in convention hotels. The word "caucus" is now spelled without a capital letter, but it is still a part of party paraphernalia.

Local Caucuses.—The caucus as a local institution is found in various towns, not only in New England but in other sections as well. The laws in many states provide for the caucus, which has to some extent become another word for direct primary. The caucus in the one state which does not have the direct primary for party nominations is provided for by law as if it were the familiar town caucus of earlier days. Yet when the Connecticut caucus law provides for the use of written ballots on request of 15 electors present at a town caucus, it definitely suggests a procedure resembling the well-known secret vote by ballot in the party primary of other states. Thus the caucus still remains, but tends to shade off into election forms of rather different character.

In England the caucus has come to signify a party gathering outside the Parliament, especially as applied to the Liberal Party caucus after 1867. "Caucus" in this sense suggests extraparlimentary party organization and local conferences or conventions.

Department of History and Political Science, University of Richmond.

CAUDATA. One of three orders of living Amphibia, the other two being the Salientia (such as frogs and toads) and the Gymnophiona (rare, wormlike animals of the tropics). The Caudata (by some authorities called the Urodela) includes the tailed Amphibia commonly known as salamanders and newts. Various species are found in North America, Europe, and Asia. Most members of the order have a superficial resemblance to lizards but differ in having a moist skin and lacking scales. Being amphibians they cannot live in a dry environment. Some species are found in moist earth under logs and stones, others occur in streams and lakes. The eggs are usually larger than those of frogs and toads. Development takes place in moist earth or water. The larval stages have external gills. In most species these are lost at the time of metamorphosis into the adult stage. A few species, such as the axolotl (*Stredon*) of Mexico and western United States and the mud puppy (*Necturus*) of eastern United States, are aquatic and possess gills throughout their adult life. The American newt (*Triturus*) passes its larval life in water. At the time of metamorphosis it changes into the red eft and spends several years on land. Then it undergoes a second change in body structure and coloration and returns to water to spend the rest of its life. The largest member of the order is the giant salamander of Japan. It attains a length of 5 or more feet. Most species are between 4 and 10 inches in length. Except for some Asiatic and Mexican species, which are used for food, the animals of this group are of little or no economic importance. They are of considerable interest to zoologists both in possessing many primitive vertebrate structures and for providing embryos and adults for experimental purposes.

JOHN A. MOORE.

CAUDEBEC-EN-CAUX, kōd-bēk'an-kō', village, France, in the Department of Seine-Inférieure, on the right bank of the Seine River, 18 miles west-northwest of Rouen. At the equinoctial high tides, the tidal wave can be seen from here, moving up the river. The 15th and 16th century church and houses were almost totally destroyed in World War II, but the templar house has been restored and turned into a museum. There is an aircraft plant. Pop. (1946) 1,575.

CAUDEX, kō'dēks, in botany, the stem, particularly the stout scaly trunk, of a tree fern or palm, or the persistent woody basal portion of a perennial herb.

CAUDINE FORKS, kō'din, a mountain pass of southern Italy, in the form of two lofty fork-shaped defiles in the Apennines, on the road

between Capua and Benevento, Campania. Here a Roman army was enticed by the Samnites in 321 B.C., and, being hemmed in, was forced to surrender.

CAUDLE'S CURTAIN LECTURES, Mrs., a series of humorous sketches by the English writer Douglas Jerrold (q.v.), published first in *Punch* in 1846.

CAUDRY, kō-drē', town, France, in the Nord Department, 40 miles south-southeast of Lille, on the government-operated railroad. Its major industries are embroideries and the weaving of fine materials; there are also sugar distilleries. In World War I the town was partially destroyed by the Germans and was occupied for a time by them in World War II. Pop. (1946) 12,091.

CAUER, kou'ēr, a family of German sculptors.

EMIL CAUER, b. Dresden, Germany, Nov. 29, 1800; d. Kreuznach, Aug. 4, 1867. He studied in Berlin under Christian Rauch. In 1825 he went to Bonn where he became instructor in art at the university; in 1832 he was appointed drawing master at the Gymnasium at Kreuznach. He invented a substitute for plaster known as the *Cauersche Masse*. Among his best works were statues of Franz von Sickingen, Charles V, and Melanchthon. He also restored antiques in the museum at Dresden.

KARL LUDWIG CAUER, son of Emil, b. Bonn, Feb. 14, 1828; d. Kreuznach, April 17, 1885. He studied with his father and with Albert Wolff in Berlin and in Rome. Among his works were the Schiller monument at Mannheim, *The Witch*, and a number of portrait busts. He designed the tomb of President James Garfield at Cleveland, Ohio. He had three sons, all sculptors: HUGO, LUDWIG, and EMIL.

ROBERT CAUER, younger brother of Karl, b. Dresden, Feb. 13, 1831; d. Kassel, April 2, 1893. He studied at Dusseldorf with his father Emil, and also at Rome. He made hundreds of small statuettes executed in the *Cauersche Masse*, whose motifs were taken from romantic or classic tales and poems. The Prussian Ministry of Public Instruction commissioned him and his brother Karl to superintend the reproduction in plaster casts of the principal structures in Italy. His son STANISLAUS was also a sculptor.

CAUGHLEY, kāf'li, site of a village in England, in Shropshire, where in the 18th century fine porcelain was made. Even before the 18th century earthenware pottery was made there, as excavations on the site have revealed. Thomas Minton (q.v.) and John Rose learned their trade at the Caughley pottery owned by a Mr. Turner, whom later they bought out. The pottery was moved to Coalport, now a famous name in English china, and the village name disappeared.

CAUGHNAWAGA, kōg-nā-wōg'ā, an Indian town, Quebec, Canada, on Lake St. Louis, opposite Lachine, about 10 miles south of Montreal. It was founded by the Jesuit missionaries in 1667 as a refuge for the Christian Iroquois who might be molested by pagan tribes.

In 1890 rule by tribal chief was changed to municipal government of a mayor and council. The Indians engage in farming, making snow-

shoes and lacrosse rackets, and guiding rafts down the Lachine Rapids. Pop. (1952) 2,240.

CAULAINCOURT, kō-lăn-kōōr', MARQUIS Armand Augustin Louis de, French soldier and diplomat: b. Caulaincourt, Aisne, France, Dec. 9, 1772; d. Paris, Feb. 19, 1827. Of noble birth, he became in 1793 a plain soldier, served in the Revolutionary armies, and was promoted general. In 1807 he was appointed ambassador to Russia and in 1808 created duc de Vicence. At St. Petersburg he tried to maintain the alliance of Tilsit, but in 1811 war broke out between France and Russia, and he returned to become aide-de-camp to Napoleon, whom he accompanied on the disastrous campaign in Russia, which he had tried to prevent. He became minister for foreign affairs in 1813 and again during the Hundred Days. After the Restoration he was on the proscribed list, but his name was removed by intervention of the emperor of Russia. His memoirs of the years 1812-1815, first published in France in 1837 and again in 1933, appeared in English as *With Napoleon in Russia* (1935) and *No Peace With Napoleon!* (1936).

CAULFIELD, kôl'fēld, city, Australia, in the State of Victoria, 6 miles southeast of Melbourne within the metropolitan area. Purely a residential suburb, it has beautiful views of mountain ranges rising to over 4,000 feet, the slopes covered with tall eucalyptus trees and shrubs. Pop. (1947) 79,913.

CAULIFLOWER, kô'li-flou-ēr (*Brassica oleracea* var. *botrytis*), belongs to the cabbage family, and has its origin in the wild cabbage still found in different forms along the coasts of the British Isles and the Mediterranean.

The number of distinct varieties of cauliflower is quite large, ranging from the small foliaged and extremely early types grown in India to the tall-growing and later-maturing Mediterranean types. They are mostly white-headed, but some are purple, some green.

In America the white-headed Erfurt and Snowball types (commonly known as cauliflower), and the cauliflower-broccoli or winter cauliflower types are mostly used. The only difference between the two lies in details of plant growth and seasonal adaptations. The cauliflower-broccoli is slower in reaching maturity and many have very definite seasonal adaptations. They are mainly grown on the Pacific coast for winter maturity. For the sake of clearness, all cauliflower-broccoli varieties should be classed as cauliflower.

The plant forms a compact white head or curd, formed by the shortened flower parts. When the head begins to develop, the leaves are drawn up together and tied, to make the heads whiter and more attractive for market. When ready to cut, usually enough leaves are left attached to the head to form protection in the container. Cauliflower prefers a comparatively cool temperature, plenty of moisture and considerable humidity, a rich loamy well-drained soil, and quite heavy fertilizing.

Seeding is done from 5½ to 7 weeks before transplanting time in greenhouse, hothed (frame), or plant bed out of doors. In some cauliflower-growing areas direct seeding is done in the field and the plants thinned in the rows.

The seed of the winter cauliflower types has

been grown in America for several years. Prior to 1940 all the seed of the Snowball types was imported from Europe, but since then it is successfully grown in some areas on the Pacific coast, where diseases such as black rot are unknown.

Cauliflower is attacked by the same diseases and insects as cabbage.

HARM DREWES,
Ferry-Morse Seed Company.

CAULKING. See **CALKING.**

CAULONIA, kou-lō'nyā, town, Italy, near the east coast of Calabria, in the Province of Reggio di Calabria, 10 miles north-northeast of Siderno Marina, on a hill 1,000 feet above sea level. It lies in an agricultural region where citrus fruit, olives, and grapes are grown.

Formerly called Castelvetero, ancient Caulonia was founded in the 7th century B.C. by Greek colonists and became a flourishing town of Magna Graecia, though it was always a dependent of Croton, a powerful colony further up the coast. When Dionysius of Syracuse defeated the first Achaean League, of which Caulonia was a member, during his conquest of southern Italy (390-379 B.C.), the town was destroyed and its inhabitants moved to Syracuse. It was later rebuilt, but never regained its former prosperity. Remains of fortifications, of a temple, and some vases were found in the vicinity. Pop. of the commune (1951) 12,996.

CAULOPTERIS, kô-lōp'tēr-īs, the name for certain stem fragments of the genus *Psaronius*, tree ferns now extinct, but occurring in the Paleozoic period. The stem fragments are characterized by the fact that they bear leaf scars in four rows. They occur in the lower Pennsylvanian (Carboniferous) beds of North America. The silicified stem fragments have been cut and polished, and sold as gems.

CAUS, kô, or **CAULS** or **CAULX**, Salomon de, Norman engineer and architect: b. Dieppe, France, about 1576; d. Paris, Feb. 27, 1626. Working in England for the prince of Wales in 1612, and in Germany for the elector palatine in 1614-1620, he returned to France to become engineer and architect to the French king. Working on hydraulic machines in 1615, he adapted hydraulic power for revolving the drum of a barrel organ. He published *Les Raisons des forces mouvantes* . . . (1615) in which he described a machine for forcing up water by steam, differing from Giovanni della Porta in having one vessel serve both as boiler and displacement chamber. On the strength of this description, although no record exists of such an apparatus having been made, the invention of the steam engine has been claimed for de Caus.

CAUSAPSCAL, kô-zăp-skāl', village, Quebec, Canada, in Matane County on the Gaspé Peninsula, and on the Matapédia River, 35 miles northwest of Campbellton, New Brunswick. It is in a dairying region and is also a resort for fishermen. Pop. (1951) 2,609.

CAUSE, in philosophy, that which brings about any change or produces any effect. The concept of cause, until recent times, has played a fundamental role in both metaphysics and the

philosophy of science. Reality has for the most part been pictured by philosophers as a cosmos, that is, an orderly whole, and causality has served as the principle of order. Aristotle's differentiation of four sorts of cause comprises the chief ways in which this principle was later interpreted: (1) efficient cause—the agency by which an effect is produced; (2) formal cause—the means or instrumentality; (3) material cause—the substance from which it is produced; and (4) final cause—the purpose or end for which it is produced. In theology, the concept of a first cause (Aristotle's "unmoved mover") has been used to establish the existence of God; the argument rests on the assumption that every sequence must have a first term, though sequences without first terms are common and consistent (e.g., the negative integers in order of size).

In scholasticism and the early modern period causality was important as entering into the orderly intelligibility of the world, a doctrine formulated in Gottfried Wilhelm von Leibniz' "principle of sufficient reason." Knowledge worthy of the name is not limited to a mere description of phenomena, but also gives an explanation of them, and explanation is ultimately causal. Initially, final causes were admissible explanations, and indeed preferred, but with the rise of modern science they increasingly gave way to efficient causation. The last great stronghold of finality was in biology, and much of the philosophical significance of Darwinism lay in its replacement of final causes by the efficient causation of natural selection.

Efficient causation itself, however, was difficult to conceptualize clearly, particularly when (as in Sir Isaac Newton's theories) it took the form of "action at a distance," for this made it impossible to picture efficiency as a matter of mechanical contact. Indeed, fatal objections to causality in this sense were formulated from a strictly empiricist standpoint by David Hume. In the conception of events of the type *A* as causing events of the type *B* are two components: (1) an invariant succession of a *B* after an *A*, and (2) a bond of necessity, constraining a *B* to occur after an *A* does. Hume pointed out that this second component never enters into experience, which manifests only the succession. Furthermore, experience does not reveal the invariance of a succession, but at most only its occurrence within the always limited range of our observations. And the inductive inference that it will also occur outside this range is justified only by the assumption of a causal connection, and so cannot be used to establish this connection on pain of circularity. Immanuel Kant attempted to reinstate causality as a category of the understanding without which experience of an orderly and intelligible world would be impossible (indeed, which is presupposed in saying that *B* objectively succeeds *A*). But this leaves unsolved Hume's problem of induction, that is, the justification for ever holding that it is indeed *A* (rather than, say, *C*) which is the cause of *B*.

The traditional philosophical conception of causality was given an influential formulation by John Stuart Mill. The famous "Mill's methods" of induction are logical consequences of the conception of a cause as a sufficient and necessary condition: the occurrence of *A* suffices for the occurrence of *B*, and *B* cannot occur without *A* occurring. The difficulties lie in determining whether in fact these relations hold.

In scientific practice causality is dissociated from any notion of efficiency or compulsion, which is regarded as a projection onto the external world of our experience of effort in bodily action on things. Causal connection is replaced by a functional relationship of a mathematical sort, one magnitude, *y*, being a function of another, *x*, if, when a particular numerical value is specified for *x*, a value for *y* is thereby determined. Here the irreversibility of the temporal order of causation is no longer important, since, when *y* is a function of *x*, *x* is an inverse function of *y*. For instance, the distance a body falls under the action of gravity being a function of the length of time it is falling, in accord with the law $s = \frac{1}{2}gt^2$, the length of time it falls is also a function of its distance: $t = (2s/g)^{1/2}$. Moreover, *y* may be a function of several variables (as in this example distance is of both time and the gravitational force); causes are not always fruitfully identifiable as single, isolable agencies. And once the mathematical function or correlation is established, no further scientific problem remains as to the agency of causal necessitation. This is not to say that intermediate connections, or relations to more general laws, are not to be searched for, but only that the efficiency of causation has no scientific content.

The doctrine that causality is universal, in other words, that every event is caused, is known as *determinism*, and is sometimes held to be a postulate of scientific method. Developments in modern physical theory—notably Werner Heisenberg's principle of indeterminacy in quantum mechanics—indicate, however, that in the realm of the subatomic, at any rate, strict determinism simply does not hold. The fixity and regularity of macroscopic events is interpreted as a statistical phenomenon, analogous to the stability of, say, suicide rates, although no inexorable destiny compels any single individual to commit suicide.

ABRAHAM KAPLAN,

Professor of Philosophy, University of California.

CAUSE CELEBRE, kōz' sâ-lëb'r' (from the French signifying "celebrated case"), a term generally applied to any criminal or civil case of special legal importance or interest, national or international. Of such are celebrated trials for political crimes, for treason, of judicial errors, of impostors, poisoners, assassins, kidnapers, or murderers.

In France a ritual murder case in which Voltaire championed the cause of the victim was that of Jean Calas, broken on the wheel in 1762; and in the 19th century the Dreyfus case (1894-1906) aroused international attention, championed by Émile Zola. In England the trial of Burke and Hare (1829) and the Tichborne case (1871-1874) were celebrated.

In the 20th century some famous *causes célèbres* were the Caillaux case (1914) in Paris; in the United States the Thaw case (1906); the Sacco-Vanzetti case (1921-1927); the Lindbergh kidnaping (1932); the Alger Hiss case (1950); and the Julius and Ethel Rosenberg case (1953).

See also ASSASSINATION; BURKE AND HARE; CAILLAUX, JOSEPH; DREYFUS, ALFRED; KIDNAPING; SACCO-VANZETTI CASE; THAW CASE; TICHBORNE TRIAL.

Consult Bataille, A., *Dramas of the French Courts* (London 1941); Roberts, C. E. B., *Famous American Trials* (London 1948); O'Donnell, Bernard, *Old Bailey and its Trials* (New York 1951).

CAUSERIES DU LUNDI, kô-zê-rês' dü lûn'dî, or **MONDAY CHATS**, the title given by Charles Augustin Sainte-Beuve to the articles which he contributed every Monday for nearly 20 years, beginning with 1849, to the daily newspapers *Le Constitutionnel* and (after 1852) *Le Moniteur*. Their 15 volumes, together with the 3 volumes of the *Premiers Lundis* and the 13 volumes of the *Nouveaux Lundis*, form an unmatched series of critical studies, of which literature is the central but by no means exclusive interest, and present a gallery of portraits in which poets and philosophers, statesmen and savants, artists and actresses, great wits, and charming and beautiful women, are painted with a wonderfully animating and revealing touch.

The range and variety of the subject matter are surprising. Few figures of significance in French life and letters of the last three centuries fail to find a place in the collection. Nor was Sainte-Beuve's view confined to his own country. He was widely read in foreign literature, particularly English. His curiosity was insatiable and his mind singularly mobile and insinuating. For such a mind criticism had to be something quite different from what it had traditionally been—a classifying and judging of literary compositions according to some definite, accepted canon of taste. The task of criticism was primarily to understand a work and a person in the light of their intention, rather than to measure them by some conventional standard. Literary works were viewed but as a partial expression of individualities, to be fully comprehended only when illumined by the light thrown upon them by complete knowledge of their author's life, times, family, friends, surroundings, circumstances, and character.

The preliminary reading that went to the making of each of these articles was prodigious. The critic could neglect nothing that could add to his knowledge of the man or woman whose work he was assessing. Sainte-Beuve did not, however, abandon standards of judgment and give himself up, like Hippolyte Taine, to explaining literature in terms of race, environment, and moment. He maintained, with increasing insistence as he grew older, the tradition of a cultivated and disciplined taste. He furthermore added to his rare qualities of intelligence and discrimination the command of an entirely adequate style, of great delicacy, brilliancy, and charm, so that the *Causeries* delight us no less than they instruct. Taken in all they constitute, with the companion series of *Portraits (Littéraires, de Femmes, Contemporains)* as imposing a body of criticism as any literature can show, and justify the almost unanimous endorsement of Matthew Arnold's estimate of their author as "the finest critical spirit of our time."

ARTHUR G. CANFIELD,

Professor of Romance Languages, University of Michigan.

Consult Trechmann, E. J., *Causeries du Lundi*, tr. with an introduction and notes, in the *World's Classics* (New York 1933).

CAUSEWAY, kôz'wâ, a raised passage across wet or marshy ground or over water, usually paved with cobblestones, pebbles, or limestone. In history it was often called a *causey*, from the Latin *calx* (lime or chalk). The most famous examples of causeways are some of the old Roman roads, the remains of which may still

be seen in parts of Europe and Great Britain, where the swamps and fenlands were bridged by causeways so well constructed as to last over a thousand years. In early New York City, a causeway was built along the old Greenwich Road, which was then on the bank of the Hudson River, and was flooded by high tides. Another early example of a causeway in the United States connected Boston Neck with the mainland. For a legendary example, see **GIANT'S CAUSEWAY**.

CAUSSES, kôs, a region of plateaus, south central France, covering parts of several departments and crossed by many rivers. It is a notable example of karst (q.v.) and an excellent region for studying the Jurassic limestone with its underground streams, fissures, potholes, prehistoric remains, and caves, which are visited in numbers by tourists. This ancient country is full of beautiful scenery, with its rivers and valleys, gorges like the Tarn, and its medieval castles and churches. On the plateaus themselves, the average altitude of which is 3,000 feet, the climate is severe. They are sparsely populated and suitable only for sheep raising. In the valleys the chief towns are Mende, Rodez, Millau, and Cahors. The Martel area produces Roquefort cheese and truffles.

CAUSTIC, kôs'tik, in *medicine*, an agent which is extremely irritant to living tissue, and sometimes causes burning or destruction of tissue. Some of the common agents are caustic alkali (the hydroxide of an alkali element), potassium hydroxide, sodium hydroxide, and toughened silver nitrate or lunar caustic. Caustics are also referred to as escharotics. They are used principally to disorganize or destroy living tissue such as warts, granulations, or superficial tumors. Other caustics are glacial acetic acid, carbolic acid, chromic acid, and the powerful mineral acids sulphuric and nitric. The hot iron is also referred to as a caustic, and tissue burned with it is said to be cauterized.

Caustic agents that are used unwisely may do serious damage since strong acids and alkalis often penetrate far beyond the area being treated. Formerly strong escharotics were used in attempts to destroy skin cancers, sometimes with disastrous results. At the present time the use of caustics in surgery is fairly limited and always has a definite purpose. In those who have been exposed to possible hydrophobia, nitric acid applied deep in the wound from a dog bite is still practiced, even though the Pasteur treatment is to be given.

In *optics*, a curve to which the rays of light reflected or refracted by another curve are tangent. It is called *catacaustic* when caused by a reflection, or *diacaustic* when due to a refraction. Mirrors and lenses so shaped as to make the caustic two intersecting straight lines will cause disappearance of spherical aberration.

HAROLD WELLINGTON JONES, M.D.

CAUSTIC SODA. See **ELECTROCHEMICAL INDUSTRIES—Caustic Soda**.

CAUTERETS, kô-à-râ', village, France, in the Department of the Hautes-Pyrénées near the Spanish border, 3,254 feet above sea level; on the Gave de Pau, 20 miles south by west of Lourdes by railroad. In summer it is a watering place where people come to take the

waters of the sulphurous springs for throat and respiratory ailments, or for rheumatism and skin diseases. Several baths dating from Roman times still exist nearby. The valley is very beautiful, with a chestnut forest, outcrops of black granite, and fine views of the mountains. In winter it is a resort for winter sports and mountain climbing. It acquired fame in the 16th century when Margaret, sister of Francis I of France, held her literary court and wrote much of her *Heptaméron* there. Pop. (1946) about 1,020.

CAUTIN, kou-tên', province, Chile, in the south central part, between the Andes Mountains and the Pacific Ocean; area, 5,519 square miles; capital, Temuco. It is drained by the Cautin, Imperial, and Toltén rivers and the lakes within its borders include Villarrica, Budi, Colico, and Caburgua. Snow-capped Villarrica Volcano, 9,317 feet high, lies within the borders of the province. Served by a state railway, steamers, and roads, the lake district attracts many tourists for its scenic beauty. Some of the major resorts are Carahue, Toltén, Villarrica, and Pucón.

The temperate climate of the province produces wheat, oats, barley, rye, potatoes, peas, and apples; cattle and sheep are also raised. There is good fishing in the lakes and forest areas are important. Flour milling, dairying, distilling, and tanning are the chief industries. Pop. (1949 est.) 321,583.

CAUTIN RIVER, Chile, in Cautín and Malleco provinces, rises in the Andes Mountains and flows about 100 miles west and southwest through the Central Valley past Lautaro, Cajón, Temuco, and Carahue to join the Quepe River three miles southeast of Nueva Imperial to form the Imperial River.

CAUTIONARY, in Scots law, an instrument in which a person binds himself as surety for another. The person executing such an instrument is known as a *cautioner*, which is the equivalent of a surety or bondsman in English and American law. Another related term in Scots law is *cautionry*, meaning suretyship. A cautionary may be either a bond to pay a debt or a written undertaking to secure the personal appearance of the party for whom the cautioner is bound.

CAUTIONARY TOWNS, three towns in the Netherlands—Brill (now Brielle), Flushing, and Ranimekens—so named because they were given to Queen Elizabeth in 1585 as security that they would repay her for assistance in their struggle with Spain. They were restored to the Dutch Republic by James I in 1616, although only a portion of the sum advanced was refunded.

CAUTLEY, kôt'li, Sir Proby Thomas, English engineer and paleontologist; b. Stratford St. Mary's, Suffolk, England, 1802; d. Sydenham, London, Jan. 25, 1871. After active service in India with the Bengal artillery, he was attached to the army engineers working on the Doab Canal, which was opened in 1830. Cautley had charge of the canal for 12 years, during which time he extended other water courses, but his greatest work was the Ganges Canal. Work began in 1843, and after some setbacks, political and others, the canal was opened in 1854. On his return to England he was made a Knight Commander of

the Bath (K.C.B.), and appointed to the Council of India.

While working in the Sivalik hills, he became interested in the fossil remains found there, and with Dr. Hugh Falconer made a great collection which was given to the British Museum, contained in 214 heavy chests. He contributed many papers to the Bengal Asiatic Society and to the Geological Society of London, which awarded him in 1837, jointly with Dr. Falconer, the Woollaston Medal. He also wrote a report in two volumes on the construction of the Ganges Canal (1860).

CAUVERY or **KAVERI** (ancient *CHABERIS*), river, India, rising in Coorg and flowing in a southeasterly direction for about 475 miles until it enters the Bay of Bengal through a wide, fertile delta, the largest arm of which is called the Coleroon. The delta has an extensive irrigation-canal system. About 35 miles east of the city of Mysore, the river is divided into two arms by the island of Sivasamudram. Each arm descends abruptly for about 320 feet to form a series of scenic rapids and cataracts called Cauvery Falls. The falls on the left arm furnish hydroelectric power. The Cauvery is filled by the monsoon rains in May and July, but it is navigable only in short sections by small boats. Often called the Ganges of the South, sections of the river at Seringapatam and Trichinopoly are regarded as sacred. The irrigation system of its delta, dating from the 2d century, is the most ancient in India.

CAVA DE' TIRRENI, ka'va dâ tîr-râ'nê, town, Italy, in the Province of Salerno, Campania, three miles west-northwest of the city of Salerno. Because of its fine location and healthful climate at an altitude of 640 feet, it is one of the most popular resorts of southern Italy. Wine, olive oil, maize, and tobacco are produced nearby. Cava de' Tirreni is a cathedral town and about two miles west is the Benedictine abbey of La Trinità della Cava, founded by St. Alferius about 1025 near the cave where he had a vision. The abbey enjoyed a period of great splendor and political power before its decline in the 15th century. Now it is national property and has a school. Some sections of the old abbey still exist, though most of the convent and the church were rebuilt in the 18th century. There are ancient frescoes, a picturesque Gothic cloister, and a collection of Lombard and Norman coins. The library includes important documents (8th-19th centuries) and illuminated manuscripts. Pop. (1936) 12,214; commune (1951) 39,086.

CAVAGNARI, ka'va-nyâ'rê, Sir Pierre Louis Napoleon, British military administrator; b. Stenay, Department of the Meuse, France, July 4, 1841; d. in battle, Kabul, Afghanistan, Sept. 3, 1879. A student at Christ's Hospital, London (1851-1857), he became a cadet in the East India Company in 1858, having been granted naturalization the previous year. With the 1st Bengal European fusiliers, he served in the Oudh campaign (1858-1859), and was decorated. His courage and ability won him the appointment of deputy commissioner at Kobat, then at Peshawar, where he took part in several expeditions against the hill tribes. In 1879 he was knighted for his services in negotiating a treaty with Yakub Khan, the new ruler of Afghanistan. While in Kabul

as British resident, the Afghan regiments mutinied and he was killed in the massacre that followed.

CAVAIGNAC, kâ-vě-nyâk', (Éléonore Louis) Godefroy, French journalist and politician, son of Jean Baptiste Cavaignac (q.v.): b. Paris, France, 1801; d. there, May 5, 1845. He took part in the revolution of 1830 and opposed the restoration of the monarchy by Louis Philippe. Taking part in the uprisings of 1832 and 1834, he was imprisoned, but escaped to England. Returning to Paris in 1841, he became one of the editors of *La Réforme*, an opposition newspaper. He was a founder of the Société des Amis du Peuple and of the Société des Droits de l'Homme in 1832, of which he became president in 1843. A fine statue of him by François Rude is in the cemetery at Montmartre.

CAVAIGNAC, Jacques Marie Eugène Godefroy, French politician, son of Louis Eugène Cavaignac (q.v.): b. Paris, France, May 21, 1853; d. St. Calais, Department of Sarthe, Sept. 25, 1905. As a schoolboy at the Lycée Charlemagne, he is said to have shown his Republican upbringing by refusing a prize from the prince imperial. He served in the Franco-Prussian War, then returned to the École Polytechnique. In 1882 he was elected to the Chamber of Deputies from St. Calais; in 1885-1886 he was under secretary of war; and in 1892 minister of marine and of the colonies.

In July 1898, while again minister of war, he forced Lieutenant Colonel Henry to confess to a forgery of certain letters bearing on the Dreyfus case, but nevertheless he declared his belief in Dreyfus' guilt. He resigned his office the following month. In 1899 he ran for president but was defeated and retired to his country home. He published *La formation de la Prusse contemporaine*, 2 vols. (1891-1898). See also DREYFUS, ALFRED.

CAVAIGNAC, Jean Baptiste, French lawyer and revolutionist: b. Gourdon, Lot, France, 1762; d. Brussels, Belgium, March 24, 1829. An advocate at the Parlement of Toulouse, he was sent to the National Convention as deputy from the Department of Lot. He rose to be one of the leaders of the Montagnards (extreme Republicans), voting for the death of Louis XVI. With his colleague Jacques Pinet, he established a revolutionary tribunal at Bayonne where he repressed his opponents with great energy. He was sent on various missions to the armies of the Moselle and the Rhine and was also a member of the Council of Five Hundred. In 1806 he became a councilor in Joachim Murat's kingdom of Naples, and during the Hundred Days he acted as prefect of the Somme. At the second restoration he was banished as a regicide.

CAVAIGNAC, Louis Eugène, French general: b. Paris, France, Oct. 15, 1802; d. St. Calais, Oct. 28, 1857. His father, Jean Baptiste Cavaignac (q.v.), played a leading part in the Revolutionary assemblies; his brother Éléonore Louis Godefroy Cavaignac (q.v.) was also an exalted democrat and a fighter for the cause of liberty and justice. Young Cavaignac graduated from the École Polytechnique, attended the military school at Metz, served in the campaign of Morea, and was appointed a captain in 1829. In 1832 he was sent to Africa, where he distinguished himself in de-

fending the French settlement against the Arabs and gained recognition as an excellent administrator and organizer. He received the rank of brigadier general in 1844 and was appointed governor of the Province of Oran. In March 1848, the provisional government of the Second Republic promoted him to the rank of *général de division* and appointed him governor of Algeria.

Soon after, Cavaignac was elected to the National Assembly by two departments, Lot and Seine. Proceeding to Paris to take his seat, he arrived there on May 17. The capital was then in a state of great excitement, because of the struggle for power between the various factions which had overthrown Louis Philippe's government: Monarchists, Republicans, Socialists, and others. The political and economic crisis was precipitated by ill-advised measures taken by the provisional government, especially by the closing of the *ateliers nationaux* (national workshops), created in order to give work to the unemployed. Cavaignac was offered the portfolio of minister of war, and on accepting took prompt and energetic steps to protect law and order. In a few days, an army of nearly 70,000 men was assembled in and around Paris. When the insurrection burst forth on June 23, Cavaignac was ready for it. After three days of tumult and bloodshed, during which more than 3,000 persons perished, the insurrection was suppressed.

On June 26, the National Assembly delegated the entire executive power to Cavaignac, who resigned it three days later, but was immediately named president of the Council of Ministers. Notwithstanding the services he had rendered, he was defeated in the elections for the presidency, in the month of December following those events. The radicals never forgave him the harsh repression of June; the Catholics and the Conservatives saw in him too strict a Republican and justly feared he would hinder the monarchist restoration they favored. Cavaignac received only 1,500,000 votes to Louis Napoleon's 5,500,000. After the coup d'état of Dec. 2, 1851, he was arrested and briefly interned in a fortress. In 1852 and 1857, he was elected a member of the legislative body but refused to take the oath of allegiance. The last years of his life were spent at his country seat in the Department of Sarthe.

Consult Deschamps, Émile, *Vie de Cavaignac* (Paris 1870); Bastid, Paul, *Doctrines et Institutions politiques de la Seconde République*, 2 vols. (Paris 1945).

PIERRE BRODIN,
Director of Studies, Lycée Français de New-York.

CAVAILLE-COLL, kâ-vî-kôl', Aristide, French organ builder: b. Montpellier, France, Feb. 4, 1811; d. Paris, Oct. 12, 1899. He was one of a family of French organ builders, including JOSEPH CAVAILLÉ, a Dominican monk, who lived in Toulouse in the first part of the 18th century; JEAN PIERRE CAVAILLÉ, his nephew and pupil (c.1740-c.1815), who made organs for southern France and Spain; and DOMINIQUE HYACINTHE CAVAILLÉ-COLL, father of Aristide (1771-1862).

Aristide Cavallé-Coll built organs for the Paris churches of Notre Dame, St. Sulpice, and the Madeleine, as well as for other churches in the provinces, and in many foreign countries. He invented the pressure method for sounding tones of different depths and heights. He published *Projet d'orgue monumental pour la basilique de Saint-Pierre de Rome* (1875).

CAVAILLON, kâ-vâ-yôn', (ancient Cabelio), town, France, in the Department of Vaucluse, on the Durance River, 13 miles southeast of Avignon at the west foot of the Montagne du Lubéron. An irrigated district, it produces excellent fruit, especially peaches and melons, and early vegetables. Its chief manufactures are tin cans and aluminum kitchen utensils.

The Romans established an important colony at Cabellio whose ruins now comprise a fragment of a triumphal arch and some tombs. From as early as the 5th century A.D. it was an episcopal city, and its present cathedral dates partly from the 12th century, with later additions. Pop. (1946) 9,412; commune 13,804.

CAVALCANTI, kâ-vâl-kân'tê, **Guido**, Florentine poet and philosopher: b. Florence, Italy, between 1250 and 1255; d. there, Aug. 28 or 29, 1300. He was a friend of Dante, who held Cavalcanti's lyric verse in high esteem (Dante's *Divine Comedy*, *Purgatory*, canto xi, 97). When the dissensions of the Guelphs and Ghibellines disturbed the public peace of Florence, the citizens banished the chiefs of both parties. The Ghibellines were exiled to Sarzana, which was so unhealthy a spot that the exiles were permitted to return; but Cavalcanti had contracted malaria, from which he died.

In his youth he made a pilgrimage to Santiago de Compostella in Galicia. Returning home through France he fell in love at Toulouse with a young lady named Mandetta. To her are addressed most of his verses, published as *Canzone d'amore*. Their beautiful style, called by Dante *dolce stil novo*, has been much admired, and many commentaries have made it their subject. The *Canzone d'amore* has been translated into English by J. B. Fletcher in *Modern Philology* in 1910, and by Ezra Pound in 1912.

CAVALCASELLE, kâ-vâl-kâ-sêl'lâ, **Giovanni Battista**, Italian art historian: b. Legnago, Italy, Jan. 22, 1819; d. Rome, Oct. 31, 1897. A student of painting at the Academy of Venice and at Munich, he traveled widely in Lombardy, Tuscany, and Rome. After his activities in the revolution of 1848, he was forced to escape to England where he became the literary collaborator of Sir Joseph Archer Crowe, with whom he produced *Notices of the Lives and Works of the Early Flemish Painters* (1857-1872); *History of Painting in Italy*, 5 vols. (1864-1871); *Life of Titian* (1877); *Life of Raphael* (English ed. 1882-1885). He was inspector of the National Museum in Florence and general director of fine arts in Rome. A new edition of his *History* was brought out by Edward Hutton, in 3 volumes (1909). A revision begun by Crowe was continued by S. A. Strong and Langdon Douglas, in 6 volumes.

CAVALIER, kâ-vâ-lyâ', **Jean**, French soldier and lieutenant governor of the island of Jersey: b. Nov. 28, 1681, at Ribaute near Anduze in Languedoc, France; d. Chelsea, London, England, May 17, 1740. Secretly brought up as a Protestant by his mother, he escaped to Switzerland at the age of 20 when threatened with persecution; but he returned on the outbreak of the revolt in the Cévennes in 1702 against Louis XIV's severe anti-Protestant measures. He became the leader of the Protestant Camisards but suffered a defeat which led to a meeting and an agreement

with Marshal Claude de Villars in 1704; Cavalier was to retain his own army and receive a colonel's commission to fight for France. Fearing treachery, however, he escaped to Switzerland. During the Spanish War in the Netherlands he raised a regiment composed largely of refugee Camisards who fought under him in Spain at the Battle of Almanza (now Almansa), where Cavalier was wounded.

In 1727 he went to England, where he received a pension, was made lieutenant governor of the island of Jersey in 1738, and in 1739 a major general. Eugène Sue made him the hero of his novel *The Protestant Leader* (1849). See also CAMISARDS.

CAVALIER, kâv-â-lêr', a term originally denoting a mounted soldier of rank as contrasted with a foot soldier; also a knight or rider. During the Civil War in England (1642-1646), the term Cavalier was given to the supporters of Charles I whose gay dress and demeanor were in sharp contrast to the austere appearance of the Roundheads who supported Parliament.

In fortifications, in earlier times, a kind of interior bastion, several feet more elevated than the principal bastion of the fortress in which it was formed. The use of the cavalier was twofold: it served either to defile the works from the fire of an enemy, or to command the trenches of the besiegers. Cavaliers were sometimes constructed in gorges or on the middle of the exterior wall, and their form was semicircular; but when they were within the bastion, they were built with straight faces and flanks parallel to those of the work in which they were placed. French cavaliers were works raised by besiegers on the glacis or slope of a fortress for the purpose of enabling them to direct a fire of musketry into the covered way.

CAVALIER POETS, a term properly applied to the group of lyrists among the followers of Charles I and of his exiled son, from the first actual warfare with the Commonwealth until the Restoration. The term is also applied more broadly to other poets of the time, such as Robert Herrick and John Donne (qq.v.), who wrote in the same style; but the distinction of the manner is due to those loyalists who were pre-eminently court gentlemen and fighters for the king.

In literary tradition the Cavalier poets took their descent from Sir Thomas Wyatt and Henry Howard, earl of Surrey; Sir Philip Sidney, Sir Walter Raleigh, and those other cultured and well-traveled "makers" of the Tudor and Elizabethan courts, who naturalized the Provençal lyric and its love system on English soil. This influence, of course, had been strong in Chaucer's time, but only with this later group did lyric poetry as an accomplishment become well established among the gentlemen around the English sovereign, and take on a native manner, truly expressive of the historical moment.

The early Elizabethan court poets, even in their narrowest imitations of the French sonneteers, had some of the largeness of the age in their manner; they spoke consciously to an audience. At the end of Elizabeth's reign the Renaissance wealth of scholarship and culture had spread through the nation, in a wide circle from the court. What remained the peculiar inheritance of the courtly poet was undergoing a refinement such as the novel shows in the second part of

John Lyly's *Euphues* (1580), in which the story is taken into the drawing room, where the feminine influence is dominant, imposing in a modern way the exquisiteness which is the end of all courts of love. By a similar transition, the courtly poets, letting go the larger subjects and the public manner, made the quality of their verse the very qualities of graceful society—the personal compliment; the brief sallies that general conversation demands; the quick turns in which grace and wit count; that method of society verse which restrains beneath an even manner all feeling that is too personal or too deep. The presence of the ladies is felt not of one woman alone; as in the garden scene in the second part of *Euphues*, the lover must find ways to woo his lady under the very eyes of her teasing comrades.

This development of the court poetry was occasioned, no doubt, by the natural growth of culture and the perfecting of manners in English society, as well as at the court. Some impression, however, was made upon the court by the change from Elizabeth's manlike rule to the gentle influence of Charles' refined queen. The influence of Henrietta Maria, however, was not altogether admirable. Refining though it was, it took the direction of effeminacy, and in the *précieuse* fashion which is fostered of insincere pedantry. William Harbington in his *ustara* (1634) illustrates the overrefinement of theme to which the graceful court verse at this moment might have seemed doomed.

The personality of Charles, however, which enlisted the loyalty of the courtiers, his tragic end, and the exile of his family and his followers, gave back to the courtly verse the vitality it was losing, and in addition some new characteristics, which distinguished it as Cavalier poetry. Loyalty to Charles and to his son, unlike loyalty to Elizabeth, was more personal than patriotic; it served to revive therefore some of the most ideal conditions of chivalry. Charles became not so much the sovereign of a country as the head of an order of knights; his exiled son became their leader under all skies. The sufferings that were the cost of their loyalty, their sense of a lost cause and the long tradition of proud breeding that would bear all with outward lightness, made the pathos and the grace of the best Cavalier poets. The Elizabethan largeness of manner never quite returned, though James Graham, 1st marquess of Montrose (1612–1650), echoed it nobly in his lines on the death of Charles I. and in those on his own execution; but in general, the lighter gracefulness continued to be a mark of the Cavaliers, as in Montrose's most famous lyric, which begins "My dear and only love." In singleness and loftiness of devotion, in the actual sacrifice of his life for the cause, and in the natural, incidental place of literature in his career, Montrose is perhaps the ideal Cavalier poet.

Richard Lovelace (1618–1658), author of the best known Cavalier lyric, "Tell me not, sweet, I am unkind," and of the only less perfect *To Althea, from Prison*, illustrates in his life, as does Montrose, the tragedy that often underlay this graceful verse, but the tragedy here is one of sentiment. He impoverished himself to give his fortune to the king. On returning from the wars abroad, he was imprisoned, and his "Lucasta," Lucy Sacheverell, believing him dead, married someone else. Lovelace died worn out by suffering and poverty.

A similarly typical fate was that of Sir John

Suckling (1609–1642), who spent his fortune for the king, became an exile, and died abroad. He wrote several plays and the clever *Session of the Poets* (1637), the model of much later criticism in light verse; his fame, however, is founded on his Cavalier poems. In his life and in his writing he is neither so noble nor so pathetic as Montrose and Lovelace; he is a roisterer at heart, as can clearly be seen even in the exquisite *A Ballad Upon a Wedding*. But he is master of the reckless tone that finally characterized the school, the tone that had been caught so finely by George Wither (1588–1667)—who strangely enough lived to be a Roundhead—in his "Shall I, wasting in despair?" In such lines as "Out upon it, I have loved three whole days together," Suckling turns the bravado note into a pretty compliment; in his best lyric, the song from *Aglaure*—"Why so pale and wan, fond lover?" he carries it to its logical conclusion of recklessness.

Among the numerous poets who wrote in the Cavalier manner, though not under strict Cavalier conditions, besides Herrick and Donne, already noticed, should be mentioned Edmund Waller (1606–1687), for his two perfect lyrics of compliment, *On a Girdle and Go, Lovely Rose*. But far more important is Thomas Carew (1595?–?1639), probably the most gifted minor poet of the time, with the exception of Herrick. He came of good family, enjoyed an excellent education, and, it seems, led a reckless life. In his verse the Cavalier compliment is most elaborate and most noble, as in the incomparable *To Celia*, beginning "Ask me no more," and in the epitaphs on Lady Mary Villiers, where he is indeed more the scholar than the Cavalier. "Give me more love or more disdain," and "He that loves a rosy cheek," are other familiar examples of his felicity. He had in full measure the rhetorical grace of the true Cavalier, the secret of splendid openings and cadences—an unacademic art that began not in literary imitation but in courtly conversation, in the fine compliment paid to beauty that need not be abashed by praise.

Professor Emeritus of English, Columbia University.

CAVALIERE SERVENTE. See CICISBEO.

CAVALIERI, kă-vă-lyă'rê, **Emilio de'** (also EMILIO DEL CAVALIERE), Italian composer: b. Rome, Italy, 1550?; d. there, March 11, 1602. His music, which differed from most compositions of his time in its simple melodic quality, attracted the attention of the intellectual Florentine families, and he became inspector general of arts and artists at the Medici court at Florence from 1589. He was one of the originators of *basso continuo* accompaniment and a promoter of the new *stile recitativo*. Some of his dramatic compositions are *Il Satiro* and *Il Giuoco della cieca* (1590); *La disperazione di Fileno* (1592); *La Rappresentazione di anima e corpo* (1600), the latter once considered the first oratorio, but really a morality play set to music.

CAVALIERI, **Francesco Bonaventura**, Italian mathematician: b. Milan, Italy, 1598; d. Bologna, Nov. 30, 1647. At the age of 15, he entered the Jesuit Order, and was sent to the University of Pisa to study mathematics, for which he showed an early bent. His teacher

there was Benedetto Castelli, a disciple of Galileo. From 1629 until his death he was professor of mathematics in Bologna, and was the author of several mathematical works, the most important of which was entitled *Geometria indivisibilibus continuorum nova quadam ratione promota*. Since he expressed in this work some original ideas concerning the abstruse sciences, the Italians claim him to be the inventor of the infinitesimal calculus. It is indeed true that his method of indivisibles enabled him to attain certain results which are now reached by the integral calculus, but Cavalieri made the false step of regarding a plane figure as the sum of a finite number of narrow rectangular strips and a solid figure as the sum of a finite number of cylindrical laminae, instead of considering the figures in question as *limits* of such sums.

CAVALIERI, Lina, Italian dramatic soprano: b. Rome, Italy, Dec. 25, 1874; d. near Florence, Feb. 8, 1944. A pupil of Mme. Mariani-Masi in Paris, she made her debut at Lisbon, Portugal, in December 1900, later singing in most of the large opera houses on the Continent. She made her debut at the Metropolitan Opera House in New York City on Dec. 5, 1906 as Fedora in Giuseppe Giordano's opera of that name. In 1909-1910 she appeared at the Manhattan Opera House, and in 1915 with the Chicago Opera Company. The roles which gained her the highest acclaim were those of Thaïs, Manon, and Herodiade. In 1913 she married the tenor Lucien Muratore, from whom she was later divorced. Retiring to Italy on the outbreak of World War II, she was killed during an American air raid.

CAVALLA. See KINGFISH.

CAVALLERIA RUSTICANA, *kä-väl-lä-rë-ä roös-të-kä-nä* (RUSTIC CHIVALRY), the title of a famous short sketch by Giovanni Verga, recounting how an "affair of honor" was settled in a country place in Sicily. The story first appeared in 1880 in a collection of tales entitled *Vita dei campi* (*Life in the Fields*) and subsequently, when the stories were reprinted, gave its name to the collection. The direct way the story is told, without any elaboration, leaving to the imagination precisely what is necessary, makes the tragedy a model of this kind of realistic writing, a kind which has given Verga a very high rank among 19th century Italian writers.

Turiddu Macca, a young soldier, returns from military duty to find that his sweetheart, Lola, during his absence has given her hand to a well-to-do villager, Alfio. To revenge himself, Turiddu wins the affection of a young girl, Santa, living directly opposite Lola, and then endeavors to make the latter jealous. He succeeds, abandons Santa, wins back Lola, and pays for his treachery with his life, in a duel with Alfio. Such are the bare facts. The way they are presented in rapid succession leading up to the tragedy is realism of the highest order. Moreover, the local coloring is so strong as to give the sketch a flavor that is peculiarly Italian, and which characterizes thoroughly everything that is presented in the tragedy: Turiddu's uniform and red cap with the tassel worn by the Bersaglieri, which strangely agitate the young girls and attract the small boys; his reproach in Sicilian dialect to Lola, just before her marriage; the ostentation of the latter after her marriage, in displaying her jewels and

ornaments from the balcony of her house to proclaim her wealth; the courtship of Turiddu and Santa, broken by Lola's jealousy, and the resulting consequences, that is, the challenge of Alfio to Turiddu; the binding of the promise to fight the duel by embracing, and by Turiddu's biting Alfio's ear; the duel at sunrise in the Indian fig field, where Alfio, wounded, stoops down, picks up a handful of dust, throws it into his opponent's eyes, thus blinding Turiddu, making it possible for Alfio to wreak his revenge by dispatching the betrayer of his honor.

In 1884 Verga dramatized *Cavalleria rusticana* as a one-act play containing nine scenes. Several minor characters appear and Santa is called Santuzza. The whole action takes place Easter morning in the village *piazzetta*, where the wine shop of Turiddu's mother, Nunzia, is seen, and the village church. Although Verga's dramatized version is effective, the drama is hardly the equal of the *novella*, the charm of which in no small degree lies in the merely suggested background.

Undoubtedly much of the celebrity of *Cavalleria rusticana* is due to Pietro Mascagni's opera of the same name, the libretto for which was written by Ottaviano Targioni-Tozzetti and Guido Menasci, shortly before 1890. Although the original version of the story is followed quite closely, several lyrics are introduced serving as texts for arias and choruses, which, admirable as they are in their way, by reason of their development rather detract from the original dramatic effect. (See CAVALLERIA RUSTICANA, the opera.)

An English translation by Alma Stretell appeared in England in *Cavalleria Rusticana and Other Tales of Sicilian Life* (1893); also one in the United States by Nathan Haskell Dole in a volume entitled *Under the Shadow of Etna* (1896). A readily available text of *Cavalleria rusticana*, with English notes and commentary, by Professors E. H. Wilkins and R. Altrocchi of Chicago University, will be found in a collection *Italian Short Stories* (1912).

JAMES GEDDES, JR.,
Professor Emeritus of Romance Languages, Boston University.

CAVALLERIA RUSTICANA, a grand opera in one act by Pietro Mascagni (libretto by Ottaviano Targioni-Tozzetti and Guido Menasci, founded on a tale by Giovanni Verga), first produced at Rome, May 17, 1890. Awarded the prize in a competition for one-act operas offered by the publisher Sozegno, *Cavalleria Rusticana* launched its composer into worldwide prominence, and founded a school of well-defined proportions. All Italy went wild over the work and Mascagni was hailed as the legitimate successor of Giuseppe Verdi. Everywhere the opera created a furore. In New York two managers vied with each other to be the first in the field, with the result that two productions were given in New York on Oct. 1, 1891, and the question of priority rights had to be settled by the courts. In the meantime, both Philadelphia and Chicago had heard it. The compressed emotional appeal of the work swept critical judgment off its feet. The hot-blooded passion of the story was raised to a higher power by the music. The *Intermezzo* alone was an eloquent advance agent of the opera. The work established the so-called *verismo* school of Italian opera, dealing with contemporary matters in realistic fashion. The Siciliana sung by Turiddu, Santuzza's romance, the Drinking Song and Lola's aria are often heard in concert. Operatic annals contain few such sensational and meteoric careers as that of *Cavalleria Rusticana*. For

more than half a century it has been often paired with Ruggiero Leoncavallo's *Pagliacci* as a double bill in the operatic repertoire. For the outline of the story see CAVALLERIA RUSTICANA.

For a detailed account of its premiere in New York and for an appraisal of the opera consult Krehbiel, H. E., *Chapters of Opera* (New York 1908).

CAVALLI, kă-väl'lê, **Pietro Francesco** (originally PIETRO FRANCESCO CALETTI-BRUNI), Italian composer: b. Crema, Italy, Feb. 14, 1602; d. Venice, Jan. 14, 1676. The name by which he is known was assumed by him in 1640 in honor of his patron Federico Cavalli, mayor of Crema. He studied in Venice under Claudio Monteverdi, whose style he continued. In 1665 he became organist at St. Mark's, and *maestro di capella* in 1668, an office he retained until his death.

He is best remembered for his work in dramatic operas, in which he introduced solos, freer rhythm, and widened the scope of dramatic possibilities. He was the direct forerunner of Alessandro Scarlatti who developed opera along these lines. In spite of obvious crudities of style and weakness of harmony, Cavalli's 42 operas are still noteworthy productions. Among them may be mentioned *Le nozze di Teti e Peloo* (1639); *Il Giasone* (1649); and *Ercole amante* (1661). About 1656, a collection of his church music was published in Venice.

CAVALLO, kă-väl'lò, **Tiberio** (English TIBERIUS), Italian physicist and inventor: b. Naples, Italy, March 30, 1749; d. London, England, Dec. 21, 1809. Very early in life he moved to England where he published in 1775 a notice of *Extraordinary Electricity . . . Observed at Islington*. He invented several ingenious instruments for electrical and chemical experiments. His apparatus for measuring the force and quantity of electricity is remarkably delicate and accurate. In 1779 he was admitted to the Royal Society. His study of the influence of air and light on plant development was brilliantly original and paved the way for valuable discoveries in organic life. He wrote *Theory and Practice of Medical Electricity* (1780); *A Treatise on the Nature and Properties of Air . . .* (1781); *Complete Treatise on Electricity* (1786); *A Treatise on Magnetism in Theory and Practice* (1787); *Elements of Natural and Experimental Philosophy*, 4 vols. (1803); and other scientific works.

CAVALOTTI, kă-väl-lòt'tè, **Felice Carlo Emanuele**, Italian politician and writer: b. Milan, Italy, Dec. 6, 1842; d. Rome, March 6, 1898. A fighter under Giuseppe Garibaldi and a political journalist, contributing to *Unità Italiana* and other newspapers, he was elected to the Italian Parliament in 1868. There he violently opposed Francesco Crispi for his stand on the monarchy, and became the leader of the radical Republicans. He served several terms in prison and fought 32 duels, being killed in the 33d. In his verse he frequently attacked the government. Some of his plays were *Agnese* (1873); *Guido* (1873); *I Merseni* (1877); *La sposa di Menecle* (1882); *Il Povero Piero* (1884). A complete collection of his works was published in Milan, in 10 vols. (1895-1896).

CAVALRY, kăv'äl-rî, that part of the military forces which serves on horseback. Cavalry has always been characterized by its mobility and by its shock action (the impact of charging horse-

men in close formation). These capabilities made cavalry the decisive influence in military operations until the introduction of muskets and artillery. Cavalry has been used for a number of missions besides attack in battle. These include (1) reconnaissance; (2) counterreconnaissance; (3) delaying action; (4) outpost duty; (5) conduct of raids; (6) pursuit.

Ancient Times.—Cavalry's development as a distinct arm followed the breeding of horses capable of carrying an armed man. By 772 B.C. lancers and mounted bowmen began to replace the chariot warriors of the Assyrian Army. The Medes and Persians, who successively replaced the Assyrians, depended mainly on horse archers. In western Europe, this evolution was slower. Xenophon mentions the use of cavalry during the First Messenian War (begun 743 B.C.), but its first employment in sizable units seems to have been at Leuctra (371 B.C.) where Epaminondas used it to secure his flanks. Philip II of Macedon (r. 359-336 B.C.), after studying these tactics while a hostage in Thebes, made cavalry the decisive arm of the professional army he raised on his return to his kingdom. Fixing the enemy by the frontal attack of his massive infantry phalanx, he would throw his heavy cavalry against their flank. Such knee-to-knee charges demanded excellent riders and careful training, since this early cavalry had neither saddles nor stirrups and could be easily dragged from their horses. Philip's army also included light cavalry for reconnaissance and skirmishing. Alexander the Great (r. 336-323 B.C.) inherited this army. At the river Granicus (334 B.C.), he defeated the more loosely organized Persian cavalry; at Issus (333 B.C.), his heavy cavalry rolled up the Persian left flank; at Arbela (331 B.C.) it led the attack through the gap which by clumsy maneuvering the Persians had opened in their center, and pursued the defeated army to its destruction. At the Hydaspes (326 B.C.), it took a stronger Indian army in flank and rear and so disorganized it as to make it easy prey for Alexander's infantry. Alexander was even able to defeat the nomadic Scythians.

Early Rome did not develop an efficient cavalry. This lack brought it repeated defeats in the Second Punic War (218-201 B.C.). Hannibal's heavy cavalry, modeled after Alexander's, was the most effective part of the heterogeneous Carthaginian Army. Though the Roman legions were superior to the Carthaginian infantry, they were shattered by cavalry attacks against their rear at the Trebia (218 B.C.) and Cannae (216 B.C.). Moreover, Hannibal's Numidian light horse was unequaled for scouting and outpost duty. Taught through bitter experience, Rome eventually built up its cavalry. In Africa, Scipio won over the Numidians. Hannibal returned to defend Carthage, but at Zama (202 B.C.) the Roman cavalry rode his horsemen off the field, then turned to strike his infantry from the rear. Carthage defeated, Rome again neglected its mounted arm. Consequently, Roman expansion eastward was blocked by the Parthian horse archers.

Early Christian and Medieval Eras.—Saddles, and then stirrups, appeared in the first centuries of the Christian era (the exact dates are not known). These innovations gave the cavalryman a firmer seat and made shock action more effective. The Goths probably used both in their annihilation of a Roman army at Adrianople

(378 A.D.). Thereafter, European cavalry evolution followed divergent paths. In the Eastern Rome (Byzantine) Empire, war was a science. Its armored horsemen, equipped with bow and lance, combined mobility, firepower, and shock action to a unique degree; such professional soldiers preserved their empire until the unnecessary disaster of Manzikert (1071 A.D.). In the West, under the new feudal system, warfare was the function (and recreation) of the nobility. The knight relied upon shock action alone. His mobility was relatively low, both from the weight of his equipment and the complete lack of any military organization. Medieval armies were temporary collections of local contingents, led by an individualistic gentry. Medieval cavalry reached its maximum efficiency during the 13th century under Charles I, count of Anjou, and Simon de Montfort. Thereafter, the increasing use of plate armor further reduced mobility to a point where armor was observed to be an excellent thing—it protected its wearer, and hindered him from injuring anyone else. At the same time, class tradition and past successes made the knight arrogantly confident in the invincibility of his ponderous charge. Therefore, the next two centuries saw him repeatedly defeated by Flemish and Scottish spearmen, English archers, Swiss pikemen, and the Hussite *wagenburg*.

Meanwhile, Genghis Khan (c.1162–1227 A.D.), one of the greatest cavalymen in history, made an empire out of the restless Mongol tribes. Carefully organized, thoroughly disciplined, his mounted army was followed by wagon trains, spare horses, and herds of livestock, giving it a capacity for sustained operations never before seen. Masters of deception, the Mongols maneuvered swiftly in widely separated columns, and concentrated unexpectedly on the enemy's flank or rear. In combat, they employed evasive tactics, luring their opponents into ambush and wearing them down by incessant archery before committing their armored lancers for the final attack. Victories were exploited by merciless pursuit. In 1241, their raiding columns reached the Adriatic. Fortunately, family feuds broke up their empire by 1300.

The 15th Through 18th Centuries.—The Hundred Years' War saw the introduction of artillery and put war on a more professional basis. Charles VII of France (r. 1422–1461), formed a permanent force of regularly paid heavy cavalry—the *Compagnies des Ordonnances du Roi*. To resist heavy cavalry, infantry armed with 18-foot pikes and covered by arquebusiers formed in masses too dense for horsemen to ride over. Cavalry countered by abandoning the lance for the pistol. Advancing at the trot in columns 12 or more ranks deep, these pistoleers (*reiters*) would fire by rank at close range, wheeling back to the rear of their formation to reload. Leg armor was abandoned, but breastplates were thickened. Various types of irregular light horse (*stradiots*, *argoulets*) were employed.

These slow tactics of the 16th and 17th centuries were upset by Gustavus Adolphus (r. 1611–1632) of Sweden, who taught his cavalry to charge at the gallop, the front rank only firing, then taking to their swords. Once this combination of firepower and shock action had swept away the hostile horse, the Swedish cavalry swung back to help their infantry. Artillery might support these charges. This return to classical tactics was carried on by Oliver Cromwell;

Louis II, prince de Condé; Henri, vicomte de Turenne; Charles XII of Sweden; and John Churchill, duke of Marlborough. Armor largely disappeared. Dragoons appeared as a separate arm about 1554. Cavalry was employed in mass. Frederick the Great (r. 1740–1786) brought cavalry to one of its highest points by strict and unceasing training and careful selection of commanders. It played a major part in most of his victories, especially the Prussian triumphs of Rossbach (1757) and Zorndorf (1758). Its major missions were close-in security and combat. The American Revolution saw little cavalry fighting because of the difficulty both sides experienced in securing sufficient horses and forage.

Napoleon and the 19th Century.—Napoleon Bonaparte evolved the concept of the cavalry screen, which covered the advance of his army, smothered enemy reconnaissance, and collected information. He also developed a cavalry reserve, mostly composed of his cuirassed heavy cavalry which he raised from one regiment in 1800 to 16 in 1810. Once the hostile army was fixed by his light cavalry and advance guard, Napoleon selected the vital spot in its position, massed his artillery there, and literally blew a hole through which he poured the reserve cavalry. Generally these tactics worked, from Austerlitz (1805) to Ligny (1815). At Eylau (1807) the cavalry had to be committed too soon; at Leipzig (1813) it was too weak; at Waterloo (1815) the cavalry attacks over rough terrain against infantry in position met with disaster. The loss of most of his veteran troops and trained horses in Russia (1812) made Napoleon's victories in 1813 barren. There could be no effective pursuit. It must be remembered that the infantry of this period was armed with a muzzle-loading musket, inaccurate even against massed troops at ranges much over 200 yards. It was slow to load, and wet weather left it useless. Infantry in squares might stop cavalry alone, but not cavalry supported closely by artillery and infantry skirmishers.

The years after Waterloo saw great improvements in infantry weapons, but none in cavalry employment. The Crimean War (1853–1856) and the Austro-Prussian or Seven Weeks' War (1866) produced numerous examples of cavalry dash and spirit, but none of its intelligent use. It was the American Civil War (1861–1865) which begot an entirely new concept. Starting with a plentiful supply of good horsemen and horses, the South was able to form effective cavalry units. Until 1863 they operated with almost complete freedom. Though seldom successful against infantry, they raided Northern communications almost at will. Brig. Gen. J. E. B. Stuart, furthermore, screened Gen. Robert E. Lee's army in a masterful fashion, while keeping him informed of every Union movement and weakness—for example, the vulnerability of Brig. Gen. Joseph Hooker's right flank at Chancellorsville. Northern cavalry developed slowly, learning like the Romans from its defeats. The adoption of the repeating carbine gave it an effective weapon, and by 1863 it began to seize the initiative. At Gettysburg (1863), Lee found himself unexpectedly engaged because the overly optimistic Stuart had committed himself to a fruitless raid instead of searching out the Northern Army. By contrast, the first Federal cavalry commander on the ground, Maj. Gen. John Buford, stopped Lee's advance for vital hours by dismounted action

west of Gettysburg. The cavalryman produced by the Civil War was a professional soldier of the highest type, equally ready for shock action with saber and revolver, or for dismounted fighting. Extremely mobile, supported by expert horse artillery, he could maintain himself in hostile territory and even storm fortifications. One feature of cavalry operations in the Civil War was the tendency toward indiscriminate raiding (usually to the neglect of more important missions) which ruined horses and produced headlines— but few other tangible results.

In Europe the many lessons of the Civil War were largely ignored. The Franco-Prussian War (1870–1871) brought out thousands of cavalry, armed and trained only for mounted action. The Prussians were at least usually active in screening and scouting; the French died bravely in futile charges against unshaken infantry.

Early 20th Century.—The South African (Boer) War (1899–1902) taught the British the importance of firepower for cavalry. The conventional type Russian cavalry, though greatly superior in number, accomplished nothing during the Russo-Japanese War (1904–1905). Nevertheless, World War I found the 10 French cavalry divisions unprepared for dismounted warfare; the 11 German divisions only partly so. Both sides frittered away their mounted forces in small detachments, the French killing a great number of their horses in aimless forced marches which had no effect whatever on the fighting. On the eastern front, the Russians finally mobilized a total of 54 cavalry divisions, yet this vast force was scattered all along the front and was of very little use. By contrast, when the two Russian armies under Gen. Pavel Karlovich Rennenkampf and Gen. Aleksandr V. Samsonov invaded East Prussia in 1914, a single German cavalry division delayed Rennenkampf's entire army long enough for Gen. Paul von Hindenburg to concentrate all other available German forces and crush Samsonov at Tannenberg.

Only in Palestine, in 1918, was there effective large-scale cavalry action in World War I. There Gen. Edmund Allenby produced a modern version of the Napoleonic attack—and a preview of World War II armored warfare—by shattering the Turkish right with infantry and artillery and pouring three cavalry divisions through the resulting gap. This cavalry exploitation and pursuit was supported by combat aviation. The improvement in automatic weapons, motor vehicles, radio, tanks, and planes after World War I seemed to leave no mission for horse cavalry. Aviation took over long-range reconnaissance; the machine gun and barbed wire prohibited charges on the battlefield. Most nations replaced the horse with the tank and armored car.

Only Poland, France, and Russia had considerable numbers of mounted men at the beginning of World War II, and these units were stiffened by the incorporation of motorized infantry, antitank weapons, and light armored vehicles. The Polish cavalry was destroyed with the rest of its army in 1939; the greater part of the French horsemen were caught in the German Ardennes breakthrough of 1940 and suffered a like fate. The Russian cavalry lost heavily in attacks on the German armored spearheads during the early part of 1941. Nevertheless, it was soon evident that sizable cavalry units could infiltrate the thinly stretched German lines and deliver attacks deep in the German rear. The

Russian cavalry seems to have normally attacked dismounted, and to have depended on darkness or the extensive forests for concealment from hostile aviation. The Germans increased their own cavalry to meet this threat, and employed mounted units of local sympathizers whenever possible. The use of cavalry on other fronts was as follows: both sides used small forces of cavalry on the Italian front; the 26th Cavalry Regiment (Philippine Scouts) covered the withdrawal of Gen. Douglas MacArthur's forces to Bataan; and both China and Japan employed large numbers of horse cavalry.

Position Today.—In the mid-1950's cavalry has become an arm for use in rough country where infantry moves slowly and motor vehicles cannot leave the few poor roads. Opportunities for shock action are few, though possibly effective due to their sheer unexpectedness. On the other hand, the improvement in automatic and recoilless weapons has increased the cavalry's firepower. With atomic warfare making a greater dispersion of ground forces a necessity, horse cavalry may still find definite, if limited missions. Russia is the only major power to retain horse cavalry as a combat arm. Armored units have taken over the combat missions, even the unit designations, of the cavalry. The armored division has replaced it on the battlefield, and the light tanks of armored cavalry regiments share its reconnaissance mission with military aviation. Shock action is no longer the physical and moral impact of massed horses and men, but of advancing armored vehicles and their firepower. The weapons have changed, but the spirit and traditions remain.

V. J. ESPOSITO,
Colonel, United States Army; Professor of Military Art and Engineering, United States Military Academy.

CAVAN, kāv'ān, 10TH EARL OF (FREDERIC RUDOLF LAMBERT), British soldier: b. Oct. 16, 1865; d. London, England, Aug. 28, 1946. He began his military career as aide-de-camp to the governor general of Canada in 1891–1893. In 1901 he served in the South African War and was mentioned in despatches. During World War I he commanded the 14th Corps, then the Brigade of Guards, and was promoted lieutenant general and made a Knight Commander of the Bath (K.C.B.). In 1918 he was in charge of operations of the 10th Italian Army on the Piave front. Promoted general in 1921, he headed the British War Office section of the delegation at the Washington Conference. From 1922 to 1926 he was chief of the Imperial General Staff, and was made colonel of the Irish Guards, an honor he retained the remainder of his life. He was created a field marshal in 1932.

CAVAN, county, Ireland, inland in the Province of Ulster, bounded on the north by Fermanagh and Monaghan, on the south by Meath, Westmeath, and Longford, and on the west by Longford and Leitrim. Its greatest length (including a long, protruding neck) is 57.5 miles and its greatest breadth, 27 miles; area 729.9 square miles. The Gaelic name, an Chabháin, signifying a hollow, comes from its low-lying central area covered with lakes. Originally Cavan was named East Breffni. The plain around Ballymagauran on the Leitrim border was the ancient pagan site of Magh Shleacht

where the pagan Irish worshiped the idol Crom Cruach. In the northeast in a wild district of mountain and bog is Cuilcagh Mountain (2,188 feet) at the foot of which the river Shannon rises. The river Erne with its tributaries flows through the center of the county. The land is hilly and not very fertile. Cavan is a county of small, frugal farmers. Oats, potatoes, and flax are grown. Near Bailieborough there is a large deposit of gypsum which is mined. The principal towns, all small, are Belturbet, Cavan, Kingscourt, Bailieborough, and Cootehill. Cavan is the county of the O'Reilly clan. Pop. (1951 prelim.) 66,412.

CAVAN, urban district, Ireland, county seat of County Cavan, 65 miles northwest of Dublin, on the Great Southern Railway, and terminus of a branch of the Great Northern. The chief section of the town was burned in 1690 when the duke of Berwick was defeated. It is an agricultural market for livestock and potatoes, and some trade in linen is carried on. Nearby is the seat of the Roman Catholic bishop of Kilmore. Pop. (1951 prelim.) 3,564.

CAVANILLES, kã-vã-nẽ'lyãs, **Antonio José**, Spanish botanist: b. Valencia, Spain, Jan. 16, 1745; d. Madrid, May 4, 1804. In 1777 he went to Paris, where he studied for 12 years, chiefly in the field of botany. In 1785-1786 he published his great botanical work *Monadelphiae Classis Dissertationes decem*, with 300 engravings. After his return to Spain he wrote *Icones et Descriptiones Plantarum Hispaniae*, 6 volumes, with 601 engravings (1791-1801). He became director of the Royal Botanical Gardens of Madrid, where he increased the collection to 12,000 species. In pursuance of a commission from the king of Spain, he collected materials for a work on the natural history of Spain, two volumes of which, on Valencia, were published at the expense of the king in 1795-1797. The plan to include all of Spain was not completed.

His nephew ANTONIO CAVANILLES (1805-1864) was a distinguished counselor and the author of a history of Spain (Madrid 1859-1864).

CAVATINA, kã-vã-tẽ'nã, (It. diminutive of *cavata*), in music, a short operatic air without repetition of words or phrases. The cavatina is composed in one section. The term *cavata* means an "extraction" but it is used to designate an epigrammatic sentence. Hence the cavatina is literally a little musical sentence.

The cavatina was used frequently in 18th and 19th century operas, and the name has also been applied to instrumental pieces of lyric character. Some notable examples are "Largo al factotum" and "Una voce poco fa" from Gioacchino Rossini's *Barber of Seville*; "Come per me serena" from Vincenzo Bellini's *Sonnambula*; a cavatina for basso buffo is found in Gaetano Donizetti's *Elisir d'Amore*; "Udite, o rustici," while the tenor cavatina in Charles Gounod's *Faust*, "Salut! demeure chaste et pure," is wellknown. Felix Mendelssohn's "Be thou faithful unto death" from his oratorio *St. Paul* is listed as a cavatina in the orchestral score, although more often it is classed as an aria. The title of cavatina is also given to the fifth movement of the great string quartette in Opus 130 by Ludwig van Beethoven.

CAVAZZOLA, kã-vãt-tsô'lã, or **CAVAZ-**

ZUOLA, Il, (real name PAOLO MORANDO), Veronese painter: b. Verona, Italy, 1486; d. there, 1522. A pupil of Francesco Bonsignori, he was considered one of the best of the Veronese school. Some of his paintings were: *Baptism of Christ*; *Madonna in Glory* (an altarpiece); *St. Rocco* and *Madonna and St. John the Baptist*, both in the National Gallery, London; of his portraits, *Ritratto di gentiluomo*, particularly fine, was in the Dresden Gallery, Germany.

CAVE, kãv, **Edward**, English printer: b. Newton, Warwickshire, England, Feb. 27, 1691; d. St. John's Gate, London, Jan. 10, 1754. After a short sojourn at Rugby School, he became apprenticed to a London printer named Collins, who sent him to Norwich to run a weekly paper, the *Norwich Courant*. In a minor government post as clerk of the franks (postfree letters granted members of Parliament), he was in a position to obtain news from members of both houses of Parliament, which he wrote as newsletters, sending them to country newspapers in several large towns. Under accusation of breach of privilege for this activity, he was dismissed from his post, and set up as a printer under the name of R. Newton. He published the first number of the *Gentleman's Magazine* under the pseudonym "Sylvanus Urban, Gent." in 1731. The magazine attained a circulation of 15,000 in a few years. One of its features was the parliamentary reports, which again brought him trouble and had to be abandoned for a time. Other famous publications by Cave were *Debates of the House of Commons, by the Hon. Achnitel Grey*, 10 vols (1745); Samuel Johnson's *Rambler*, q.v. (1750-1752); Dr. Newton's *Compleat Herbal* (1752).

CAVE, **George**, 1st VISCOUNT CAVE, English jurist: b. Cheapside, London, Feb. 23, 1856; d. Burnham-on-Sea, Somerset, March 29, 1928. After leaving Oxford he was called to the bar in 1880 becoming a barrister in 1904. In 1913 he was made counsel to the University of Oxford, in 1914 attorney general to the prince of Wales; and in 1915 he became a privy counselor and a solicitor general, and was knighted. David Lloyd George gave him the cabinet post of home secretary in 1916. When he became a viscount, in 1918, he took his seat in the House of Lords and was offered the highest judicial post in the kingdom, that of lord chancellor. He played a leading part in most of the crucial problems of his day, such as the Home Rule Bill of 1911 and 1912; the trial of Sir Roger Casement (q.v.) for treason; the police strike; and compulsory military service. Another honor he particularly enjoyed was his election to the chancellorship of Oxford University in 1925.

He was ably assisted by his wife, ANNE, (nee MATHEWS), who wrote of their travels to Zanzibar, Rhodesia, Canada, and the United States, and of their home in Richmond, Surrey.

CAVE ANIMALS. The animal life of caverns falls into three categories: (1) animals, mostly extinct, that made their dens or left their bones in caves, and in life were members of the next group; (2) animals that temporarily, but habitually, resort to caves for refuge, or sleep, or as breeding places; and (3) animals, degenerate, confined to an underground life throughout their whole existence. None of these classes include those animals making small caves for them-

selves, the burrowers; or which, like the mole and many insects, dwell in the soil; or, like the conies (hyrax), the pikas, and several sea birds, spiders, and other animals, seek safe homes among the interstices of loose rocks.

Prehistoric Cave Beasts.—The first group will require little space, as it consists of such extinct animals as the cave bear, cave lion, cave leopard, cave hyena, cave wolf, and some smaller ones that have been given these names because their bones and portraits have been found abundantly in the floors or on the walls of caverns in Europe and Africa. Indications trusted by geologists and archaeologists combine to show that these animals lived there in the latter part, at least, of the third interglacial epoch, and on through the fourth and last glacial advance, when, although central Europe was free from an icecap, an almost Arctic climate prevailed, with much rain. This is what is known as the Reindeer period, when humanity was represented by the Neanderthal race. (See *STONE AGE—Neanderthal Cave Dwellers.*) The weaker part of the fauna disappeared, but those hardy carnivora, finding food still plentiful, gradually adapted themselves by increased hairiness to the cold climate; but apparently they resorted far more than previously to the shelter of caves.

None of those mentioned above is regarded as anything but a larger, more vigorous variety of the lion, leopard, wolf, or spotted hyena except the cave bear, *Ursus spelaeus*. This beast was the most thoroughly spelaeon of all in its habits, and occupied caves before men began to do so. It was not much if any larger than the ordinary brown bear of today, and its claws were shorter and feebler. "Hence it would appear," says Henry F. Osborn, American paleontologist, "that the Neanderthals had driven out from the caves a type of bear less formidable than the existing species, but nevertheless a serious opponent to men armed with the small weapons of the Mousterian period." Probably fire and smoke were the most effective means. These bears were numerous, for game was abundant. A single cavern in western France has yielded remains of more than 800 skeletons; and from these bones and from prehistoric drawings it is possible to know this animal perfectly. With the close of the last period of partial glaciation, and the return in the early Pleistocene of the moderate climate that still continues, these and the other cave-haunting beasts disappeared, largely, no doubt, killed off by the better-armed Neolithic hunter. The great bear left no descendants, for the modern European brown bear traces its lineage to an older and smaller species, the Etruscan bear, whose bones also are occasionally exhumed from cave floors.

Caves in North America present different conditions from those of Europe. Those that have yielded animal remains, such as the Port Kennedy and Frankstown caves in Pennsylvania, and the Concord Fissure in Arkansas, "are hardly caverns" says William B. Scott, American geologist, "in the ordinary sense of the word, but rather narrow fissures, into which bones and carcasses were washed by floods." They contain a great variety of mid-Pleistocene species, at least half of which are extinct. Big Bone Lick Cave, in Kentucky, is more truly a cave, and has furnished paleontology with an immense supply of bones of recent time, including several ancient species, such as mastodons, mammoths, and the ground sloth, *Megalonyx*, and with certain traces of human pres-

ence. Caves in northern California are also rich in animal remains, illustrating the transition from glacial to modern faunas. Brazilian caverns have yielded much also; and a cavern near Last Hope Inlet, Patagonia, is noteworthy for the finding in it of the bones, and large pieces of the still hairy skin, of a great extinct sloth, *Megatherium*.

Temporary Tenants of Caves.—In modern times, as anciently, bears and other carnivora use caves as sleeping places when it is convenient, but they are exclusively resorted to by a few kinds of creatures that may properly be called cave tenants. The most characteristic of these are probably certain bats, especially such insect-eating kinds as the leaf-nosed, the horseshoe, and the true bats of the family Vespertilionidae. Caves frequented by bats usually harbor enormous colonies, and one who enters and disturbs them will find himself in the midst of a whirring multitude which taxes the powers of description. Some caves long occupied contain vast deposits of the richest possible guano, and this has been extensively utilized in some places as a fertilizer. Such artificial caverns as the deserted tombs of Egypt are filled with bats, one species of which is popularly called the tomb bat and abounds in the interior of the Great Pyramid.

Birds of two sorts are cave tenants. The most singular, probably, is the large guacharo, or oil-bird, of the family Steatornithidae, classified between the nightjars and the owls and inhabiting northern South America and the island of Trinidad. It inhabits both seaside and mountain caverns, going forth only at dusk to get its food, which is mainly fruit. "Visitors to the breeding caves," says Arthur Evans (*Birds*, 1900) "are suddenly surrounded by a circling crowd of oil-birds uttering loud croaking or rasping cries. . . . The numerous nests . . . are flat, circular masses of a clay-like substance placed on ledges or in holes." Great numbers of these birds are killed by torchlight for the sake of the oil obtained from them, which is excellent for illumination or for cooking purposes. The other birds choosing sea caves as a breeding place are swifts of the genus *Collocalia*, whose nests are placed in the depths of caves on the coasts of Ceylon, and eastward and southward to northern Australia. The best known of the many species is that which produces the edible nest of which the Chinese are so fond. Huge numbers of these swifts breed in company in dark caves, where they are associated with bats; but the bats go outside at night and the swifts by day. Such caves contain very rich deposits of guano which are exceedingly profitable to their owners.

Blind Inhabitants.—A special cave fauna exists in all parts of the world, consisting of an assemblage of animals of different classes which are blind, and in most cases eyeless. This fauna is evidently of great antiquity, since it exists most plentifully in caves, such as those of the limestone district of the South Alleghenian region, and in southern Europe, regions which are south of the Pleistocene glaciation. Within such caves, formed by the action of water, are rivers, sink-holes and deep wells, all perfectly dark, inhabited by blind amphibians, fish, crayfish, and other crustaceans, and by many kinds of insects and spiders. No vegetation exists save a few scattered molds and fungi, and all the animals are carnivorous, preying on each other. Mammoth Cave in Kentucky contains about 75 species of these blind creatures, to which 40 or 50 more may be

added from other southern caves; while several hundred kinds have been described from European caverns.

The most striking and interesting form in Mammoth Cave is the blindfish, *Amblyopsis spelaeus*. It is about four inches long, colorless and blind, the eyes being vestigial. This fish seeks the dark and shuns the light, being much disturbed by a lighted match or bright sunlight, or even by a ray of light. In well-fed adult specimens there is no external indication of an eye; but in young ones, before reaching a length of two inches, the eyes can be distinctly seen, owing to their pigment, which is lost in the adult. The optic nerve can be traced in examples under an inch in length. This will apply to the eyes of other blind fishes and blind insects, crustacea, and other blind creatures. While the sense of sight is lost, that of touch in the blindfish, as in most other cave animals, is exalted. *Amblyopsis* is provided with tactile papillae, arranged in ridges on the front and sides of the head. They are said to show extreme timidity in their movements.

A still higher type of vertebrate, two species of salamanders, have become adapted to cave life, losing their eyesight by disuse. The species of the genus *Spelerpes* frequent damp, dark situations and the entrances to caves. An allied form (*Typhlotriton spelaeus*) is distinctly a cavernicolous as distinguished from a twilight species, and has never been found outside caves. Its eyes show early stages of degeneration. It inhabits caves in southwestern Missouri, and occurs under rocks in and out of water. Still another salamander, whose eyes are the most degenerate known among amphibians, is the *Typhlomolge rathbuni*. It lives in subterranean streams, tapped by an artesian and also a surface well, near San Marcos, Texas, and in one of the caves near that town. Its remarkably long and slender legs are too weak to support its body when out of water.

The lower animals tell the same story of degeneration, total or partial atrophy of the eye, together with loss of color, and, in a more striking way, the compensation for the loss of vision by a great increase in length of the antennae and other appendages, or by the growth of long, slender tactile bristles.

The blind crayfish, *Oreonectes pellucidus*, is a common cave form. It differs from its out-of-door allies in being blind, deaf, slender-bodied, and colorless. Other blind or eyeless crustaceans are various kinds of amphipods and isopods, both aquatic and terrestrial, of which species the *Caecidotea* are the most abundant, and form the food supply of the blind crayfish.

The eyeless beetles of caves (*Anophthalmus*) have no vestige of eye or of optic nerves, while their bodies and appendages are slender. They grope their way about by means of very long tactile bristles. Other beetles, such as *Adelops*, which have retained vestiges of the outer eye, some spiders comprising an eyeless species, and others with eyes varying in size, some much reduced, spin little webs on the walls of the chambers. Among the harvestmen some (Phalangides) have extraordinarily long legs; while the Campodeidae (q.v.), a wingless insect of the Mammoth and other caves of the United States and Europe, differs from the outdoor form in its antennae and abdominal appendages, being greatly exaggerated in length. There are also mites, myriapods, primitive wingless insects (podurans), a few flies, worms, and infusorians.

Origin and History.—The blind fauna of caves, according to Alpheus S. Packard, American entomologist, is composed of the descendants of individuals which have been carried by various means into the subterranean passages, have become adapted to life in perpetual darkness, becoming isolated, and thus, as long as they are subjected to their peculiar environment, breed true to their species, and show no tendency to relapse to their originally eyed condition. The absence of the stimulus of light causes the eyes, through disuse, to undergo reduction and atrophy. With this goes, in certain forms, the loss of the optic ganglia and optic nerves.

ERNEST INGERSOLL.

CAVE BEAR, an extinct species of European bear, *Ursus spelaeus*, closely allied to the living grizzly, but attaining a larger size. Its remains are found in bone beds of caverns, whence the name. The habits of the animal were probably not different from those of most modern bears. The cave bear of South America was a different animal (*Arctotherium*). The species found fossil in the caverns of North America include both *Arctotherium* and close relatives of the black bear, *Ursus americanus*. See also BEARS.

CAVE DWELLERS. Both ancient and modern man have utilized caves as dwelling places to a considerable extent. In North Africa today there are large colonies of troglodytes who live in underground chambers in a highly civilized area. Most dwellers who now live in caves are in areas where construction of surface homes is difficult because of lack of construction materials. Temporary shelter is often gained in caves during modern wars by people who have suffered destruction of their homes.

Most of our knowledge of ancient man has come from material preserved in caves. Probably man's first dwellings were in caverns or rock shelters that gave ready protection against both weather and animals. In Europe and Asia numerous discoveries of early man have been made in caverns, the most outstanding being the remains of Neanderthal man found in a cave in Gibraltar. The skeletal remains were encountered during excavations in the limestone in 1848. Several years later another find of Neanderthal man was made in a cave encountered in quarrying in the Rhine Valley of western Germany. Remains of man older than Neanderthal were found in the Choukoutien Cave near Peiping, China, in 1929.

Ancient man did not use caves merely as temporary shelters. In the Lascaux Cave in Dordogne, near Bordeaux, France, and in the Altamira Caverns in northern Spain, discovered in 1879, are beautiful drawings executed in color by Cro-Magnon cave dwellers over 20,000 years ago. In the Montespan Cavern in the foothills of the French Pyrenees, Norbert Casteret discovered a group of clay statues of animals carved by cave men as ancient as the artists of Lascaux. Other traces of ancient cave men have been found in Belgium, England, and southern Germany.

In the Near East, caves have been associated with both Biblical history and ancient man. The Mt. Carmel Cave near Jerusalem, excavated in

1929, contained a succession of human remains and artifacts dating from Neanderthal man to the present. In Iran and northern Iraq remains of ancient cave-dwelling men associated with implements of the Stone Age have been found in many limestone caverns. Some of the caverns, such as Pastun Cave, contained evidence they were inhabited for 7,000 years or more.

The most ancient remains of man that have been found were from a cave at Sterkfontein, South Africa. Excavations in these caves by Dr. Robert Broom, in 1948 and 1949, yielded well-preserved skulls of "ape men" probably representing the link between earliest humans and the ape-like stock that preceded them.

Near Ajanta and Ellora in Hyderabad State, India, are the celebrated cave temples. About 30 of these caves were excavated from the soft volcanic rocks by followers of Gautama Buddha about 200 B.C. Some 700 years later the caverns were enlarged and more than 30 new ones constructed by Hindus who followed the Buddhists in the region. The caves are in a cliff over 200 feet high, and are adorned with columns and frescoes. Within the caves are statues, some decorative, some religious. The statues carved by the Hindus represent the peak of their art.

Until the 20th century there were few finds made of ancient man in the caves of America. In the latter part of the 19th century many artifacts of modern and pre-Columbian Indians were uncovered in excavations in shelters and caves in the Appalachians and the Ozarks. However, no skeletal remains were found that could be considered parallel in age to those recovered in Europe.

In the late 1920's and 1930's several caves were excavated in the southwestern United States that contained a sequence of human occupation as far back as 25,000 B.C. The material recovered from these caves was well-preserved because of their extreme dryness. The oldest of the caves, at Sandia, N. Mex., contained relatively modern Pueblo material at the surface, underlain by artifacts of the Folsom culture and remains of extinct ice age animals. Still lower were more ancient deposits with remains of extinct animals including primitive horses, mastodons, and mammoths, and evidences of human occupation in the form of fireplaces and spear points. The lowest level is estimated to be 25,000 years old.

Near Las Vegas, Nev., Gypsum Cave contained a record of human settlement dating back over 10,000 years. Like Sandia Cave, the upper levels of the cave fill had remains of relatively modern Paiutes. Below this were artifacts of early Pueblos and still older Basket Makers. Still lower deposits, separated from those above by thick layers of dirt and rock fall, contained two fireplaces and implements imbedded in dung of the ground sloth. Radiocarbon dating of the dung gave an age of 8,000 to 10,000 years and clearly demonstrated that man had arrived in America before the extinction of the ice age animals. Another Nevada cave that yielded material similar to that of Gypsum was Etna Cave near Caliente.

Ventana Cave in southern Arizona has yielded many relics of human occupancy. Though more numerous than those found in Gypsum and Sandia caves they are of somewhat younger age. Other caves with remains of ancient man include Conkling's Cavern and Burnett Cave in New Mexico, the Basket Makers' caves in the Rio Grande Valley of western Texas, and several small rock shel-

ters in Oregon. It is interesting to note that although caves have yielded ample material in the form of weapons, utensils, and remains of animals that probably served as food, no skeletal remains of the ancient men who inhabited the caves have been recovered.

Prehistoric man in America not only used caves for habitation but also for burial purposes. Many shelters in the southern Appalachians, the Ozarks, and bluff shelters in the Great Plains have yielded human remains that were buried with implements, jewelry, and other artifacts. Although not so old as the remains recovered in southwestern caves, they have given important information on some pre-Columbian Indians in eastern North America. In Puerto Rico, Haiti, and Cuba a number of caves were used as dwelling places by the ancient Caribs. These caves contained a large quantity of archaeological material concerning the pre-Columbian Indians of the West Indies.

The cliff dwellers of the southwestern United States were a form of cave man. Their dwellings in Arizona, New Mexico, and Colorado were elaborate, multistoried buildings erected in large shelter caves. Behind and beneath the dwellings chambers were often cut in the soft rock to extend the living quarters, or for burials.

Modern caved dwellings are found in a belt from southern China through India, Asia Minor, the Mediterranean lands, and the West Indies. In this area are many large shelter caves in soft rock that have been converted for human use. In southern France the cave house now consists of an old caved dwelling used for storage and a recent house built in front of it. In China large cave mouths have been used by placing houses in them. In Asia Minor, in an area known as Cappadocia, are a number of conical hills that have been honeycombed by caves excavated for dwellings. Some of these excavations date back to 1900 B.C. The cave dwellings in Algeria, Tunis, and Morocco consist of shallow cavate openings made in cliffs or dug beneath the ground in which both humans and their livestock dwell. See also **CAVES OR CAVERNS; MAN, PREHISTORIC RACES OF; STONE AGE—Neanderthal Cave Dwellers.**

H., *Early Man in America* (Austin, Texas, 1952).

WILLIAM E. DAVIES,
National Speleological Society.

CAVE MEN are literally men who have occupied, or do occupy, caves as residences. In popular use the term most often refers to prehistoric times, when primitive men dwelt in the shelter of overhanging rocks and cavern roofs, because they had not yet learned how to build houses. This is the fact in a certain early stage of primitive culture; and it will be found treated in its proper historic place in the article **STONE AGE**. For the human occupation of caves for residence and various other purposes within historic times see **CAVE DWELLERS**.

CAVE TEMPLE, a cave used as a temple; but the name is especially applied to temples excavated in the solid rock, such as exist in considerable numbers in India. Such caves often contain striking paintings. See **CAVE DWELLERS**.

CAVEAT, kă'vê-ăt (meaning let him beware), a formal notice to a court or a public official not to perform certain acts or continue certain proceedings. The term is ordinarily used in connection with the probate of wills, or the appointment of executors or administrators for the estates of decedents. It was formerly used in connection with the obtaining of patents.

In probate proceedings, a caveat is a petition filed by an interested party to contest a will (q.v.) which has been offered for probate by the executor. Various objections to the will, such as an allegation that the testator was insane and lacked the mental capacity to dispose of his property, or that the requisite number of witnesses did not attest the will, may be made in a caveat. Where a person's name has been cut from a will, he may enter a caveat which both contests the altered will and proposes the original instrument for probate. A caveat serves to stay the probate proceedings until the facts affecting the validity of the will are determined by the court. In some states, a caveat serves only to warn the court that a will may not be entitled to probate, and it may be filed by a stranger as well as by an interested person. When a person applies to a court for appointment as administrator of the estate of a decedent, there are various procedures established by local practice for objecting to his petition, one of which is the caveat. In such a proceeding, the caveat is, in effect, an answer filed by an interested party to contest the application for appointment.

Under a statutory provision repealed in 1910, a caveat was formerly a part of the procedure for obtaining a patent. It consisted of a notice to the patent office that the person filing it (known as the caveator) claimed to be the inventor of a particular device. The utilization of this procedure entitled the caveator to be notified prior to the issuance to any other person of a patent on the device described.

CAVEAT EMPTOR, a legal maxim meaning "let the buyer beware," is found in a number of different contexts. Its most common use is in the law of sales, where it represents the opposite of the concept of "implied warranty." The law has gradually departed from the former concept and moved toward the latter, as a guiding principle in determining the rights and liabilities as between buyers and sellers of goods. Under the early common law rule, where the idea of *caveat emptor* predominated, the seller was not liable to the buyer for the bad quality of an article sold unless he himself was aware of the quality. Under the Uniform Sales Act, however, which states the generally accepted modern rule, the law implies a warranty or condition as to the quality or fitness for a particular purpose in cases where the buyer relies on the seller's skill and judgment, or where the goods are bought by description. On the other hand, where the buyer has examined the goods, the rule of *caveat emptor* still applies as to defects which such examination ought to have revealed.

In most sales, the law implies a warranty that the seller has a good title, thus making the rule of *caveat emptor* inapplicable with respect to ownership. However, in connection with judicial sales, such as execution sales and sales by receivers, executors, and guardians, the courts frequently use the phrase *caveat emptor* to indicate the risk assumed by the buyer that the goods pur-

chased are actually owned by the debtor, ward, or other person on whose behalf they are sold, applying the maxim with varying degrees of strictness.

CAVEDONI, kă-vă-dō'nê, **Giacomo**, Italian painter: b. Sassuolo, Italy, 1577; d. Bologna, 1660. Thought to have been a pupil of Annibale Carracci, he was strongly influenced by the Venetian school, particularly by the art of Lodovico Carracci and Giacomo da Bassano. The frescoes which he painted have not survived. His sense of color and his handling of light were particularly admired. His greatest works are considered to be *The Nativity* and the *Adoration of the Magi* (1612-1613) for the Church of San Paolo in Bologna; *The Virgin and St. Alo* (1614), now in the art gallery in Bologna; and *The Miracle of the Last Supper* (1621-1622) for the Church of San Salvatore in Bologna.

CAVELL, kăv'1, **Edith Louisa**, English nurse: b. Swardeston, Norfolk, England, Dec. 4, 1865; d. Brussels, executed during the German occupation of Belgium, Oct. 12, 1915. The daughter of a clergyman, she became interested in hospitals while traveling in Bavaria and in 1895 entered the London Hospital as a probationer. In 1897 she took charge of a typhoid hospital in Maidstone, Kent, and in 1906 she went to Brussels at the invitation of Dr. Antoine Depage, a distinguished surgeon, who had established a training school for Belgian nurses in a suburb of Brussels and desired to modernize the nursing system of the country. Until that time Belgian nurses had been recruited chiefly from the ranks of nuns and domestic servants—the former attending mainly to Catholics and the latter to non-Catholic patients. In 1907 Miss Cavell became matron of Depage's clinic, which developed into a large nursing organization throughout Belgium.

At the outbreak of World War I she was in England on a visit, but returned at once to Belgium and converted her institute into a hospital for wounded soldiers. Dr. Depage was called into military service to organize military hospitals in Belgium, while Miss Cavell continued her work in Brussels. During the German occupation of the city—from Aug. 20, 1914—she was permitted to remain in control of the hospital. For the first year of the war she nursed without discrimination Belgians, French, British, and Germans. During this time, with the aid of friends in Brussels, she was instrumental in conveying many of the wounded Allied soldiers—upon their recovery—across the frontier into Holland, whence they were able to rejoin their armies. She also assisted Belgians of military age to escape capture by the Germans.

Her activities were discovered by the German authorities through the agency of a Belgian traitor (who was found murdered in the street nearly a year later), and on Aug. 5, 1915, she was arrested and lodged in the military prison of St. Gilles. She was kept in solitary confinement for three weeks before the fact of her arrest became known. At the request of the British government, the United States minister in Brussels, Brand Whitlock, took up the case and addressed an inquiry (Aug. 31, 1915) to Baron von der Lancken, the chief of the political department of the German military government in Belgium. When no reply had been received after 10 days, Whitlock wrote again and was informed (Sep-

tember 12) that Miss Cavell's defense was in the hands of a Belgian advocate, Sadi Kirschen, and that no interview could be permitted. The legal adviser to the United States legation, M. de Leval, then endeavored to communicate with the prisoner, but as was usual in the procedure of such courts in Germany, neither was the prisoner allowed to see her own advocate before the trial nor was he permitted to see the documents in the case. On October 4, de Leval was informed that the trial would be held on October 7—nine weeks after the arrest.

By frankly admitting the charge brought against her, Miss Cavell had given the prosecution evidence that otherwise would have been unobtainable. According to the German military code the offense was treason and punishable by death. The trial ended on the following day (October 8) and judgment was reserved. The officials of the United States legation made the most strenuous efforts to obtain information regarding Miss Cavell's fate: at 6:20 p.m. on October 11, Hugh Gibson, the secretary, officially was informed that the decision had not yet been given. At 8 p.m., M. de Leval heard by accident that the sentence of death had been passed at 5 p.m. and that Miss Cavell was to be shot at 2 in the morning. Whitlock was ill in bed at the time, but he wrote a personal letter to Baron Moritz Ferdinand von Bissing, the military governor, while Gibson, de Leval, and the Spanish ambassador formed a deputation of appeal for mercy or at least postponement of sentence. They were dismissed about midnight and two hours later Edith Cavell fearlessly faced the firing squad. During an interview with a British chaplain she remarked, "I have seen death so often that it is not strange or fearful to me. Standing as I do in view of God and eternity, I realize that patriotism is not enough. I must have no hatred or bitterness toward anyone."

A monument to her memory has been erected in St. Martin's Place, Trafalgar Square, London, England.

CAVEN, kāv'ën, **William**, Canadian educator and minister: b. Kirkcolum, Wigtonshire, Scotland, Dec. 26, 1830; d. Toronto, Canada, Dec. 1, 1904. In 1847 he emigrated with his parents to Canada, where they settled in Dumfries township, near Galt. At 18 he entered the theological seminary of the United Presbyterian Church at London, Ontario, and was ordained in 1852. He was pastor of the United Presbyterian Church at St. Mary's, Canada West, from 1852 until 1866, when he was called to the chair of Biblical exegesis in Knox College, Toronto. In 1873 he became principal of the college and in that office (until his death) he was largely instrumental in raising funds for its new buildings. Caven contributed greatly toward the union of the various Presbyterian bodies of Canada in 1875, in which year he was moderator of the united church—a post which he held again in 1892. By his wise foresight, statesmanlike grasp of affairs, and moderating counsels, he rendered service of inestimable value in the consolidation and the upbuilding of the Presbyterian Church in Canada. From 1900 to 1904 he was president of the Pan-Presbyterian Alliance.

CAVENDISH, kāv'ën-dīsh, **LORD Frederick Charles**, second son of the 7th duke of Devonshire, English statesman: b. Eastbourne, Sussex,

England, Nov. 30, 1836; d. Dublin, Ireland, May 6, 1882. Graduating from Cambridge University in 1858, he was private secretary to Lord Granville from 1859 to 1864. He sat in Parliament as Liberal member for the north division of the West Riding of Yorkshire from 1865 until his death. After serving as private secretary to the prime minister, William E. Gladstone (1872–1873) and acting as financial secretary to the treasury (1880–1882), he succeeded W. E. Forster as chief secretary to Earl Spencer, the lord lieutenant of Ireland. On the afternoon of May 6, he and Thomas Henry Burke, an unpopular subordinate, were stabbed to death in Phoenix Park, Dublin. Eight months later, 20 "Irish Invincibles" were tried for the murder, and James Carey and two others having turned queen's evidence, five of the rest were hanged, three were sentenced to penal servitude for life, and the remaining nine were imprisoned for various terms. Carey himself disappeared; but in July news came from South Africa that he had been shot dead on a ship by an Irishman named Patrick O'Donnell. O'Donnell was brought to London, where he was tried and hanged.

CAVENDISH, George, English biographer: b. ?1500; d. ?1561. He became gentleman usher to Thomas Cardinal Wolsey about 1527 and remained in close attendance upon his great master until the latter's death, Nov. 29, 1530, after which he retired, rewarded by Henry VIII for his services, to his house at Glemsford, Suffolk, where he lived quietly with his wife, a niece of Sir Thomas More, until the close of his own life. His affection for the cardinal was most devoted, and his *Life of Cardinal Wolsey* is one of the most interesting short biographies in English. Written in 1557, it may have been read in manuscript by Shakespeare, whose view of Wolsey corresponds to that of Cavendish. Published in an unsatisfactory state in 1641, it was not until 1885 that it appeared in polished form in the *Universal Library*.

CAVENDISH, Georgiana, DUCHESS OF DEVONSHIRE (eldest daughter of John, 1st Earl Spencer), English leader of society: b. June 9, 1757; d. London, England, March 30, 1806. Mentioned by all the leading literary lights of her day and painted by the most skilled portrait painters, such as Thomas Gainsborough and Sir Joshua Reynolds, Georgiana has come down to us not only as a reigning beauty and a lady of fashion, but also as a woman of intellectual ability, fine manners, and charm. She wrote some verse herself, but was the subject of many poems by others. Among her friends were Dr. Samuel Johnson, Charles James Fox, Richard Brinsley Sheridan, Mme. Fanny d'Arblay, Horace Walpole, the prince of Wales, Charles Cornwallis, and many others.

CAVENDISH, Henry, English chemist: b. Nice (now in France), Italy, Oct. 10, 1731; d. London, England, March 10, 1810. A grandson of the 2d duke of Devonshire, after his education at Peterhouse College, Cambridge, he devoted himself to scientific research. He lived in quiet retirement, never marrying, and having no interests besides his scientific studies. He was rather eccentric and had an impediment in his speech. His first researches dealt with arsenic and in 1765 he made some notable investigations con-

cerning heats of liquefaction and vaporization which were not published until much later. He discovered the peculiar properties of hydrogen and the qualities by which it is distinguished from atmospheric air. To him we owe the important discovery of the composition of water. Karl Wilhelm Scheele, the German chemist, had already observed that, when oxygen is mixed with double the quantity of hydrogen, this mixture burns with an explosion without any visible residuum. Cavendish repeated this experiment with the accuracy for which he was distinguished. He confined both the gases in dry earthen vessels, to prevent the escape of the product of their combustion, and found that this residuum was water, the weight of which was equal to the sum of the weights of the two gases. Antoine Laurent Lavoisier confirmed this conclusion in later times. Cavendish also obtained the anhydride of nitric acid from nitrogen and oxygen, by the electric spark.

Cavendish determined to constant K in the law of gravitation $f = \frac{Kmm^1}{d^2}$, where m and m^1 are the masses of two bodies, d the distance between them and f the measure of their mutual gravitational attraction, and thus was able to determine the mean density of the earth. He found it to be 5.45 times as great as the density of water—a conclusion which differs but little from that obtained by Nevil Maskelyne in another way. The apparatus used consisted of two large fixed masses of lead and two smaller masses near these at the ends of a rod suspended by a wire at its middle. It was devised by the Rev. John Mitchell. Cavendish was a member of the Royal Society of London and in 1803 was made one of the eight foreign members of the National Institute of France. His writings consist of treatises in the *Philosophical Transactions* from 1766 to 1809. The Cavendish Physical Laboratory in the University of Cambridge is a monument to his memory.

CAVENDISH, Margaret, DUCHESS OF NEWCASTLE, English writer: b. St. John's near Colchester, Essex, England, 1624; d. London, Jan. 7, 1674. The daughter of Sir Thomas Lucas, Margaret is notable chiefly for her autobiographical record of the way in which young ladies of means were reared in the 17th century. As the youngest of a family of eight, three boys and five girls, she had ample material for her sketch. The Civil War interrupted the happy family life, and she became maid of honor (1643-1645) to Queen Henrietta Maria. While in attendance on the queen in Paris she met and married William Cavendish, later duke of Newcastle. Until the Restoration they were very poor. She wrote many poems, essays, and plays, as well as the autobiography mentioned, and a memoir of her husband. Many of her contemporaries considered her work of more value than does later critical estimate.

CAVENDISH or CANDISH, Sir Thomas, English navigator: b. Trimley St. Martin, Suffolk, England, about 1555; d. at sea off Ascension Island, June 1592. Having been in his own ship in Sir Richard Grenville's expedition to Virginia in 1585, he returned with him to England and prepared for a voyage modeled on that of Sir Francis Drake in 1577. A complete account of this adventure was recorded by a fellow-adventurer. With three small vessels he sailed from Plym-

outh in 1586 by way of Sierra Leone, Africa, where he attempted to burn the town, proceeding to South America, spending some time in Patagonia, where a harbor was named Port Desire after his own ship. He passed through the Straits of Magellan during a great storm, took and destroyed many Spanish vessels, ravaged the coasts of Chile, Peru, and New Spain, and returned by the Cape of Good Hope, having circumnavigated the globe in two years and 51 days, the shortest period in which it then had been effected. For this exploit he was knighted by Queen Elizabeth. In 1591 he set sail on a similar expedition which was unsuccessful. Accounts of his voyages may be found in Richard Hakluyt's *Principal Navigations, Voyages, and Discoveries of the English Nation* (1589).

CAVENDISH, William, DUKE OF NEWCASTLE, English general: b. 1592; d. Dec. 25, 1676. James I made him a Knight of the Bath in 1610 and in 1620 raised him to the peerage as Viscount Mansfield. Charles I made him earl of Newcastle in 1628 and appointed him in 1638 tutor and governor to his son Charles, prince of Wales (afterward Charles II), whom he taught to be a fine horseman. When the Civil War began, he embraced the royal cause and received a commission constituting him general of all the king's forces raised north of the Trent, with ample powers. Through great exertions and the expenditure of large sums from his own personal fortune, he levied a considerable army, with which, for some time, he maintained the king's cause in the north. In 1643 he obtained a complete victory over Lord Fairfax on Adwalton Moor and recovered all Yorkshire except Hull; but next year on the arrival of the Scottish Army and its junction with the parliamentary forces, he threw himself into York. Having been relieved by Prince Rupert, he was present at the Battle of Marston Moor (1644), after which he left the kingdom. His term of exile was chiefly spent in Antwerp, where he was for a long time so straitened in circumstances that he had on one occasion to pawn his wife's jewels. He returned after an absence of 16 years and was rewarded by Charles II, for his services and sufferings, with the title of duke of Newcastle. Besides plays and poems Cavendish wrote *La methode et invention nouvelle de dresser les chevaux* (1657), repeated in *A New Method . . . to Dress Horses and Work Them According to Nature* . . . (1667).

CAVENDISH, William, 1ST DUKE OF DEVONSHIRE, English statesman: b. Jan. 25, 1640; d. London, England, Aug. 18, 1707. Traveling abroad during the civil wars, at the Restoration he was elected member of Parliament for Derby in 1661. He volunteered for service in the navy and was present with the duke of York at the fight with the Dutch off Lowestoft (1665). Standing for the rights of Parliament, he served on many committees and made important speeches in the House of Commons relative to the behavior of the king's ministers. When he succeeded his father to the earldom in 1684, he took his seat in the House of Lords and was involved in a quarrel which led to his retirement while the famous house of Chatsworth (still a show place) was being built. He was secretly involved in the cause of William of Orange and when William succeeded to the English throne in 1688, at the coronation he acted as lord high steward. In

1694 he was created duke of Devonshire and marquess of Hartington.

CAVENDISH, tobacco which has been softened and pressed into quadrangular cakes and often sweetened with sirup and molasses, for chewing, so called after Thomas Cavendish. It is also called negrohead.

CAVENDISH EXPERIMENT. See CAVENDISH, HENRY.

CAVES or **CAVERNS**, natural openings within the earth, generally extending beyond the zone of light. Caves are found in many types of rock but are most common in limestone, dolomite, and gypsum, which are readily dissolved by ground water. Sandstones having considerable quantities of lime cement between their grains also give rise to solution caves. Caves in the form of lava tubes, some several miles in length, are common in extensive lava fields, particularly in the western part of North America. These caves are formed when successive lava beds from volcanic eruptions cool and solidify, trapping liquid lava that leaves open tubes when it escapes to flow to the surface. A third type of cave is found along sea or lake shores where the shoreline is cliffed or steep in slope. Waves attack zones of weakness in the face of the shore, and cut openings in the rocks which eventually develop into large cave-like passages.

Small caverns also develop along fissures, joints, or faults where slight movements of the rock give rise to small openings. Broken rock debris in the form of talus often contain large interconnected voids that are referred to as caves. One such "cave" in New Hampshire is large enough to be operated as a tourist attraction.

Origin of Solution Caves.—The origin of solution caves in limestone and related rocks is complex, and scientists are not in full accord as to the exact sequence of events that lead to the eventual formation of a cave. In all solution caves at least three related phases of development are recognized: (1) In the first phase openings are developed in the rock by solution and are integrated to form cavern passages. (2) The second phase involves the filling of these passages with clay, silt, sand, or gravel, the source of which is the surface soils or rock in the vicinity of the cave. At times these deposits of cave earth accumulate to such an extent they completely fill the primitive passages of the cave. (3) The third stage is a reverse of the second and results in the partial removal of the earth fill by streams flowing in the cave. The streams also modify and enlarge the primitive passages. Simultaneously the reopened passages receive deposits of calcite or other minerals that are carried through the rocks in solution. The deposition of these minerals on or from the walls and ceilings of passages develops beautiful stalactites, stalagmites, columns, flowstone, or other formations that are attractions in many caves opened for public inspection. During this stage the ceilings of many cavern passages are weakened by stresses exerted upon them so that they no longer support their own weight and collapse, forming large piles of rock known as breakdown.

While the three phases of development outlined are recognized by most scientists, there are two schools of thought as to the timing and po-

sition of each phase. On one hand it is believed that all three stages occur simultaneously at or near the top of the ground water in the earth. Those holding this view (known as the one-cycle theory) advocate that water descending from the surface of the earth into the ground dissolves the limestone to form cavern openings. At the same time some of the water containing large amounts of dissolved materials precipitates them on reaching the openings forming stalactites, flowstone, and other cavern formations. Earth fills also are brought in from the surface by the descending waters at the same time that the passages are being enlarged by solution. On the other hand, another group of scientists believes that each phase is distinct and separate (known as the two-cycle theory); the first phase occurs well below the top of the ground water; the second phase at or near the top of the ground water level; and the third phase in the zone between the top of the ground water and the surface of the earth.

Age of Caverns.—The age of caverns is still an unsolved problem. Many estimates have been based on the rate of growth of stalactites, fossil remains in the cavern fills, and on the rate of solution within the cavernous limestones. The figures arrived at by these methods have been of little consequence, as they are not directly tied to the origin of the cave and at best are minimum ages. Recent work in the Appalachians and Ozarks indicates caverns are closely related to erosion levels of the earth surface and that they were probably developed simultaneously. On this basis some caverns in central and eastern North America originated as far back as the Cretaceous period of geologic time with the bulk of the Appalachian caves dating from the end of the Tertiary period.

Description.—Caves have many different shapes and patterns of passages. In most caves, passages are formed primarily along joints. Faults and bedding planes are secondary in controlling the direction of passages, but often are important in developing the shape of the passages. In plan most caves are either a series of simple sinuous or subangular passages, or a complex maze of interlacing, relatively straight passages, the layout of which is similar to city blocks. The latter plan is generally found in caves developed at the point where the rocks are gently bowed upward. Passages are usually arranged vertically in levels. In caves in mountainous regions these levels are often separated more than a hundred feet. Each level of passages is relatively horizontal, both in flat-lying or steeply dipping limestones.

In size the cavern passages range from small openings which require crawling to pass through, up to giant galleries several hundred feet wide and long. Most passages, however, are relatively small with enough room to permit walking. Floors are generally formed of smooth or stream-scoured earth fills which in some caves are covered with broken fragments of fallen rock. Pits, some small with gently sloping sides, others 50 feet or more across with vertical sides over 200 feet deep, interrupt the floor in many cavern passages. In some passages deposits of calcite in the form of smooth sheets or low sinuous dams (rimstone) cover the floor. Most cavern walls are bare rock, at times with a thin covering of wet clay. In a small percentage of cavern passages beautiful deposits of minerals known as

formations occur and in many commercialized caves they are the principal tourist attraction. Those formations hanging from the ceiling are stalactites; those deposited upright on the floor are stalagmites; while those deposited in sheets or layers on the walls or floors are flowstone.

Atmospheric conditions in caves are very uniform. At the entrance, temperatures and humidity approximate surface conditions. Beyond a short zone of transition the temperature and humidity show little variation. At most times the temperature within the cave is close to the mean annual surface temperature of the region in which the cave is located. Humidity is close to 100 per cent except in some caves with abundant gypsum or other mineral deposits where humidity generally is low. In caves with passages connecting two or more surface openings, strong air circulation takes place between entrances giving rise to the term "blowing" cave. If the circulation alternates in direction at an entrance, successively blowing in and out, the phenomenon is known as a "breathing" cave. Another unique meteorological feature of some small caves, particularly lava caves, is the large accumulation of ice and freezing temperatures found in them throughout the year even though the surface temperature rises very high in summer. Several of these caves are located in desert areas in the southwestern United States and many of them are well-known in the mountains of Europe and Asia.

Location.—Caves are generally located in areas known as karst lands. Karst is the surface expression of the subterranean solution of limestone that develops caverns. Karst landscapes are pitted with sinkholes, vertical shafts, and long blind valleys which lack surface outlets. Karst soils are usually thin, and bare bands of limestone, known as *karren* or *lapiez*, form much of the surface. In karst areas there is little surface drainage as most streams flow underground through cavernous passages reaching the surface in the form of large and numerous springs.

The most famous of the karst and cavern areas in North America are in Kentucky and Tennessee. In these states plus adjacent areas of Indiana and Illinois there are over 20,000 square miles of limestone that are "karstified." Sinkholes dot much of the landscape and in places there are as many as 1,000 sinks per square mile. On the plateau surrounding Mammoth Cave in central Kentucky there are sinkholes over a mile in diameter with steep slopes over 300 feet deep that have resulted from collapse and subsequent solution of underground chambers. Passages in these caves are mainly large galleries extending for miles; gypsum is present in many of the caves. The large caves in this region, like most of the large caves in the eastern United States, are in limestones assigned in geologic age to the Mississippian system. Within this cavern area are some of America's most famous caves.

Mammoth Cave (q.v.), with over 30 miles of known passages, was discovered in 1799 and after a long history as a private commercial cave it became a national park in 1936. In the same region with Mammoth Cave are five other large commercial caves including Crystal Cave, which was owned and developed by Floyd Collins whose death in a small cave nearby attracted worldwide attention in 1925. In central Tennessee, Higginbotham Cave, which rivals Mammoth in size, is one of the largest noncommercial caves in the

United States. Wyandotte Cave in southern Indiana is one of America's oldest known commercial caves, having been discovered in 1798, after which it was operated for saltpeter until 1850 when it was opened to the public. In eastern Kentucky, near Mt. Vernon, is the Great Saltpeter Cave which, along with Mammoth Cave, was the source of much of the niter used for gunpowder during the War of 1812 and the Mexican War. It was first dug for saltpeter in 1794.

In the Appalachian Mountains there are numerous cave areas. In general, the caves are smaller but more highly decorated than those in the plateaus of Kentucky and Tennessee. The Great Appalachian Valley, extending from New Jersey to Alabama, is floored with limestone of Ordovician age and contains numerous beautiful caves, the most famous being Luray Caverns (q.v.) in Virginia, viewed by many thousands of tourists since its discovery in 1878. Weyers (Grand) Cave near Waynesboro, Va., is probably the oldest existing commercial cave in America, having been opened to the public in 1804. Madison Cave, close by, is reputed to have been opened commercially shortly before the 18th century, but for a brief period only.

In southeastern West Virginia is a region of limestones of Mississippian age that contains caverns of immense size similar to those found in Kentucky. Within this area is Organ Cave made famous by Thomas Jefferson's description of fossil bones found in it in 1799. Elsewhere, throughout both the Appalachian Mountains and plateau are many limestone valleys and ridges with thousands of small, little-known caves in them.

In the central United States, the Ozark region of southern Missouri and northern Arkansas is an important cavern region. Although there are numerous large caves and large springs in this area, other karst features are generally lacking. Other important cavern regions of the Midwest are the Black Hills of South Dakota and the Driftless area of southwestern Wisconsin. In southeastern New Mexico and western Texas are large areas of limestone, Permian and Cretaceous in age, that contain large, deep caverns, including the famous Carlsbad Caverns (q.v.), reputed to be the largest in the world. Limestones continue south through the interior of Mexico and are very cavernous, ending in Yucatán, where there are deep well-like pits, known as *cenotes*, in the karst. These *cenotes* served as sacrifice pits for the ancient Mayas. Another famous West Indian cave and karst area is northwestern Puerto Rico where the ground is so honeycombed with subterranean passages that it has been described as a "lot of cave held together by a little limestone." Similar conditions exist in western and central Cuba and in central Jamaica, which is well-known for its "Cockpit" country.

In Europe and Asia there are extensive karst and cavernous areas. Northern Italy and Yugoslavia are renowned for their large caverns and sinkholes. The Pyrenees of southern France contain the deepest cave in the world, its lower levels being over 2,000 feet below its entrance. In eastern Belgium and western Germany are caverns that are well-known because of the remains of ancient man found in them. In the Urals, the Caucasus, and other parts of the southern USSR are extensive caverns and karst, some of which are noted for the presence of radium. Other noted cavern areas are in central England, North Africa, southern China and Indochina, the

islands of the East Indies and in parts of southern and southeastern Australia.

Commercial Aspects.—Most people who visit caves tour those that have been developed for commercial purposes. Commercial caves have graded paths, elevators, and in the case of Postumia Grotto in Italy, an electric tramway to make traverse of the cave safe. Electric lights are now extensively used but formerly kerosine lanterns or pine torches were the main source of illumination. In the United States there are about 130 caves opened commercially and throughout the rest of the world there is probably an equal number. Thirteen caves in the United States have been set aside as parts of national parks or monuments including such famous ones as Carlsbad (New Mexico), Mammoth (Kentucky), Wind and Jewel (South Dakota). In America the commercial cave business is quite large with some caverns attracting as many as 500,000 visitors a year, and it is probable that over 2,000,000 persons annually visit a commercial cave.

Aside from the commercial aspects, caves have little economic value at present. However, previous to the development of modern chemical methods they were an important source of saltpeter used in the manufacture of gunpowder. In all the wars up to the Civil War in the United States, caves in the Appalachian Mountains and adjacent areas in Tennessee and Kentucky were worked extensively for saltpeter. During the Civil War a large part of the Confederate Army's gunpowder was made from saltpeter dug from caves in Virginia, West Virginia, Tennessee, Alabama, and Georgia. The saltpeter, in the form of calcium nitrate, is contained in the earth fills on the floors of caves. It was removed by leaching with water and mixing with wood ashes to produce potassium nitrate. Caverns have been considered for use as shelters in warfare but in general have been found unsuitable because of the irregular size of passages and the danger of flooding. Large deposits of sand, clay, and guano in many caves have already proved to be economically valuable.

Speleology.—The study of caves is known as speleology and those who explore caves are speleologists. In America the scientific studies of caverns and related features were not systematized until the late 1930's. In France, Germany, Austria, Italy, Yugoslavia, and England serious study has been devoted to caves since the latter part of the 19th century. In 1895 the Société de Spéléologie was founded in France and shortly thereafter similar societies were established in several European countries. In America the National Speleological Society, founded in 1939, has brought together most of those interested in caverns of the Western Hemisphere. In addition to the countries cited above, speleological societies exist in Spain, Switzerland, Bulgaria, Czechoslovakia, the USSR, and Belgium.

Harlen, "Vadose and Phreatic Fractures of Limestone Caverns," *Journal of Geology*, 50: 675-811 (Chicago 1942); *Bulletins of the National Speleological Society* (Washington, D.C., 1940-); reports dealing specifically with caves, published by the state geological surveys of Maryland, Pennsylvania, Virginia, and West Virginia.

WILLIAM E. DAVIES,
National Speleological Society.

CAVIANA, kă-vyă'nă, island, Brazil, in the

north mouth of the Amazon River, belonging to Pará State. Its town of Roberdello is almost exactly on the equator. About 47 miles long and 20 wide, the island is fertile and is used for some cattle raising. Pop. (1940) about 1,900.

CAVIAR or **CAVIARE**, kăv'i-är, a table delicacy prepared from the roe of the sturgeon, particularly in Russia. Astrakhan, on the Volga River, is one of the chief centers for its export. Of recent years, sturgeon caught in the United States, particularly in the Delaware River and on the north Pacific coast, has been utilized. To prepare the caviar, the ovaries are removed from the fish and are beaten to loosen the eggs, which then are put through a sieve to separate them from the tissues, are soaked in brine or other preservative, then drained and packed in oaken kegs, jars, or cans. The best Russian caviar, prepared with less salt, is difficult to preserve and is transported in ice. There are black, red, green, brown, and gray varieties varying in size from a small grain to a pea. A pressed caviar is packed in tin or glass, but is considered much inferior. Its most popular use is as an hors d'oeuvre served with vodka or other liqueurs. See also STURGEON.

CAVIGLIA, kă-vē'lyă, Enrico, Italian army officer: b. Finale Ligure, Italy, May 4, 1862; d. there, March 22, 1945. Educated at Turin Military Academy, Caviglia took part in the Eritrean War (1888-1890 and 1896-1898); served as Italian observer in the Russo-Japanese War (1904-1905); and as commander during the Tripolitan War (1911-1912). In World War I he commanded the 24th Corps which broke the Austrian lines on Bainsizza Plateau (1917), and commanded the victorious 8th Army at Vittorio Veneto (1918). Promoted general in 1919 and minister of war from January to June, 1919, he expelled Gabrielle d'Annunzio from Fiume in 1920, and in 1926 was made a field marshal. An opponent of fascism, he is thought to have plotted with Marshal Pietro Badoglio in 1943 to remove Benito Mussolini from office.

CAVITE, kă-vē'tă, province, Philippines, in the southwestern part of the island of Luzon. Bounded on the north and northwest by Manila Bay, on the northeast by Rizal Province, on the east by Laguna Province, and on the south and southeast by Batangas Province, it has an area of 498 square miles. In the south and southwest the province is mountainous; in the northwest there is a gradual elevation, forming a fertile plateau. The chief products of the lowland regions are coffee, sugarcane, fruits, and rice; in the towns of the interior hemp, cotton cloth, and sugar are manufactured; in the coastal towns the chief industries are salt manufacture and fishing. Cocoanuts also are grown. Communication with Manila and inland is by water and by road. The province includes Corregidor Island (see CORREGIDOR).

In the Spanish-American War, after the Battle of Manila Bay (1898), Cavite was occupied by United States troops, who freed it from Spanish control. The government of the province was established in 1901; later several islands were added to the province. It suffered from the Japanese invasion in World War II, was retaken by the American forces in 1945, and became part of the Republic of the Philippines in 1946. Pop. (1948) 262,550.

CAVITE (officially CITY OF CAVITE), city, Philippines, capital of the Province of Cavite on the land of Luzon. Its location on a peninsula in Manila Bay, 8 miles south of Manila, makes it a good naval base and trade center. Originally an old walled Spanish town, it was the scene of Filipino insurrections before its liberation in 1898. The naval base of Sangley Point just north of the city was seized on Jan. 2, 1942, by the Japanese in World War II and was retaken on Feb. 13, 1945, by United States forces after heavy bombardment. When the Philippines became independent in 1946, the base at Sangley Point was retained by agreement as an operational area for the United States Navy. Pop. (1948) 35,052.

CAVO-RELIEVO, kă'vô-rê-lê'vô, a system of relief in which the figures do not rise above the general surface of the material on which the carving is done. It may be regarded as sculpture in relief, of which the background has not been cleared away in the usual manner. Again, it may be considered as sculpture of which the bounding line has been marked by a groove, generally wedge shaped, that is, with a section like a V: the slope of one side being left as the boundary of the pattern or design, while the other slope disappears in the general rounding of the figures.

CAVOUR, kă-vôor', CONTE Camillo Benso di, Italian statesman: b. Turin, Italy, Aug. 10, 1810; d. there, June 6, 1861. His father was the Marchese Michele Benso di Cavour and his mother the daughter of the conte di Sellon of Geneva. Graduating from the military academy of Turin at the age of 16, with highest honors in mathematics, history, and languages, he journeyed to England to study the workings and principles of its constitution. Finding military life uncongenial, he resigned his commission in 1831 and assumed the management of his father's estates at Leri, Piedmont, which he made one of the model agricultural properties of Italy. In 1842 he returned to Turin and soon afterward published in the *Bibliothèque Universelle* of Geneva, a paper on *Considerations on the Present State and Future Prospects of Ireland*. With Conte Cesare Balbo and others he established in 1847 the journal *Il Risorgimento*, which was devoted to the cause of reform, independence, and national unity.

In 1848, Cavour became a member of the Sardinian Chamber of Deputies, and after the Battle of Novara (1849), in which the Piedmontese were defeated by the Austrians, and Charles Albert resigned in favor of his son Victor Emmanuel II, he became politically active. In 1850 he succeeded to the office of minister of commerce and agriculture, to which he later added the portfolios of the navy and of finance. He set himself to promote the internal prosperity of the country by the establishment of railways and an improved system of postal communications. A new organization was given to the military and naval forces, and the monasteries were, with certain exceptions, suppressed.

His aggressive national policy made Cavour very prominent, and in November 1852 he became premier. Not long afterward he gave a signal proof of his statesmanship by the part which he took in cementing an alliance with Great Britain and France and in making common cause with these powers and Turkey in the

Crimean War (1854-1856) against Russian aggressions. The prestige thus gained to the arms of Sardinia was no less important than that acquired by her liberal and reforming policy in civil matters. The attitude, however, thus taken by Sardinia could not fail to prove extremely offensive to the neighboring power of Austria, to whose arbitrary and repressive measures the government of Victor Emmanuel displayed itself as a standing reproach and whose supremacy in Italy was jeopardized by the aspirations of Sardinia. A collision, therefore, was inevitable, resulting in the campaign of 1859.

This conflict was foreseen by Cavour, who had made a secret agreement with the French emperor at Plombières-les-Bains, France (1858). The intimate connection formed at that time with France, who lent her powerful assistance in the prosecution of the war, was mainly due to the agency of Cavour, who was accused, on this occasion, of having purchased the assistance of Napoleon III by unduly countenancing his ambitious projects. Napoleon, however, secretly signed a treaty of peace with Austria, thus deserting Italy before the close of the war. Cavour, broken-hearted, retired to private life, but was recalled to the head of the government in 1860. In October of that year he secured the passage of a bill by the Piedmontese Parliament authorizing the government to incorporate in one union such provinces of southern Italy as should express their desire by a plebiscite. This was one of the differences which he had with Giuseppe Garibaldi who, having led his volunteers to battle, wished to be dictator of southern Italy. In 1861 all Italy was united save Rome and Venetia.

The marriage of Victor Emmanuel's daughter, Princess Clotilde, to Jérôme Bonaparte, Napoleon III's cousin, occurred in 1859, and the cession of Nice and Savoy to France at the end of that year, not without protest from Garibaldi. Another cause of dissension was over the officers, who expected to retain in the regular army the ranks which they had held as volunteers.

These differences brought some unpopularity to Cavour, but after his death his devotion to the cause of united Italy was fully recognized. See also RISORGIMENTO, THE; VICTOR EMMANUEL II.

Consult Cadogan, Edward, *The Life of Cavour* (London 1907); Thayer, W. R., *The Life and Times of Cavour*, 2 vols. (London 1911); Matter, Paul, *Cavour et l'unité italienne*, 3 vols. (Paris 1922-26); Strachey, Marjorie G., *Massini, Garibaldi and Cavour* (Harrisburg, Pa., 1938).

CAVY, kă'vī, any of several rodents of the family Caviidae, related to the capybara, pacas, and agoutis, two rather distinct subfamilies being recognized. The typical caviés (Caviinae) are characterized by their stout build, short legs, small ears, and total absence of tail. About 15 species are known, widely distributed in South America and occurring in both the highlands and the lowlands. The only species familiar to most persons living outside that continent is the domesticated guinea pig (q.v.), which is about eight inches long and owing to its harmlessness and adaptability is often kept as a pet or laboratory animal. The subfamily Dolichotinae consists of considerably larger animals with longer legs confined to southern South America. The larger and better-known Patagonian cavy, *Dolichotis australis*, is reddish in color and has the size and the habits of a hare.

Caviés of several species occur in the Plio-

cene and Pleistocene periods of South America, as is shown by numerous fossils; these extinct forms differed little from modern caviés. Caviés live in burrows of their own digging and breed twice a year, the number of young varying with the climate, but usually being one or two. The young are born in a very advanced state of development. Their eyes are open, they can run in a few hours' time, they are able to feed themselves on the next day. Their diet is vegetarian.

Consult Hudson, William Henry, *The Naturalist in La Plata* (London 1892); Lydekker, Richard, *The Royal Natural History* (London 1893-96).

CAWDOR, kô'dēr, village and parish, Scotland, in Nairnshire, five and one-half miles southwest of Nairn, three miles from a railroad junction. Cawdor Castle, nearby, on the banks of the Cawdor Burn, a tributary of the Nairn River, has a central tower, built in 1454, with battlements, drawbridge, and a moat, but is surrounded with 16th century additions. Tradition assigns it as the place where King Duncan was murdered in 1040 by Macbeth, a legend perpetuated by William Shakespeare in his tragedy *Macbeth*. Pop. (1951) 823.

CAWDOR, Thane of, a character in William Shakespeare's *Macbeth*, who does not appear upon the stage. On account of his alliance with the Northmen he was condemned to death by Duncan, king of Scotland, who bestowed his title on Macbeth, as the witches prophesied (*Macbeth*, Act I, scene 3). In describing his death it is thought that Shakespeare had reference to the execution of the earl of Essex, Robert Devereux, when he says, "Nothing in his life became him like the leaving of it."

CAWEIN, kâ-win', **Madison Julius**, American poet: b. Louisville, Ky., March 23, 1865; d. there, Dec. 8, 1914. One of America's minor poets, Cawein's verse is often exceedingly musical and displays great command of meters. Its defects are overornamentation and a too profuse employment of adjectives, but the note which he strikes is distinctive and pleasing. He is at his best in his Kentuckian poems on nature. His *Complete Poetical Works*, in five volumes, were published in 1907; *Selected Poems*, with a foreword by William Dean Howells, in 1911; and a final volume, *The Cup of Comus*, in 1915.

CAWNPORE, kôn'pôr (since 1948 officially KANPUR), city, India, capital of Cawnpore District in Uttar Pradesh, on the Ganges River, 115 miles northwest of Allahabad. Cawnpore is a major industrial center and a railroad junction for trade in grains, woolens, cotton, jute, tanneries, boots and shoes, textile products, machinery of many kinds, and a dozen other thriving industries. There is an agricultural college, a law college, and a technological institution.

As Cawnpore, it is associated in history with the Sepoy Rebellion, or Indian Mutiny, of 1857, when the native soldiers under the Raja Dundhu Panth of Bithur, called the Nana Sahib, rebelled. Gen. Sir Hugh Massy Wheeler, the commander of the European forces, defended his position for three weeks with great gallantry, but, pressed by famine and loss of men, was at length induced to surrender to the rebels on condition his party would be allowed to leave uninjured. A safe conduct was promised; but after the European troops,

with the women and children, had been embarked in boats on the Ganges, the rebels treacherously fired upon them, killed about 600, including the general, and conveyed about 200 survivors back to the city, where the men were massacred and the women and children placed in confinement. The approach of Gen. Sir Henry Havelock to Cawnpore in July aroused the brutal instincts of the Nana, who ordered his prisoners be slaughtered and their bodies thrown into the well of Cawnpore, since marked by a memorial. Pop. of the urban district (1951) 719,385.

Consult Trevelyan, Sir George Otto, *Cawnpore* (London 1865).

CAXAMARCA. See CAJAMARCA.

CAXIAS, kâ-shê'ās, the name of three cities in Brazil.

(1) CAXIAS, in northeast Maranhão State, northeastern Brazil, on the navigable Itapecuru River, 182 miles southeast of São Luis on the São Luis-Teresina Railroad. It has an airport. The chief trade is in cotton, sugar, babassu nuts, tobacco, and cereals. It is the birthplace of the poet Antonio Gonçalves Dias. Pop. (1940) 7,042.

(2) CAXIAS, now DUQUE DE CAXIAS, in Rio de Janeiro State, southeastern Brazil, near Guanabara Bay, 10 miles north-northwest of Rio on the Federal District Railway line. Manufacture of motors, processing of flax, and jute milling are main industries. There are also orange groves. Pop. (1950) 74,557.

(3) CAXIAS DO SUL, in northeastern Rio Grande do Sul State, southern Brazil, 60 miles north of Porto Alegre. Founded by Italians about 1870, it was called Caxias until 1944. Cattle and hogs are slaughtered here; it is a wine-growing center and is the terminus of a branch railroad. Agates are found nearby. Pop. (1950) 32,158.

CAXTON, kâks'tûn, **William**, first English printer: b. Tenterden, Kent, England, about 1422; d. London, 1491. In 1438 he was apprenticed to Robert Large, a mercer in London, and five years after his master's death (1441) he went to Bruges, where he went into business on his own account. About 1463 he became governor at Bruges for the English merchants settled in the Low Countries, a post in which he continued for some years. He visited Utrecht during three years and was able, with the assistance of two English envoys, to restore the old commercial relations between England and the Low Countries. In 1469 he arbitrated a dispute between English and Genoese merchants.

About 1471 Caxton entered the service of Margaret, duchess of Burgundy, sister of Edward IV of England. He had begun a translation of the popular romance entitled *Le recueil des histoires de Troie*, which he finished at Cologne in 1471. To meet the demand for the book, he learned the art of printing, probably at Cologne, and his *Recuyell of the Historiyes of Troie*, the first English printed book, appeared about 1474, having issued, it is supposed, from the press of Colard Mansion at Bruges. His *Game and Playe of the Chesse*, also a translation from French, was probably a production of the same press in 1475 and is the second English book printed. He left Bruges in 1476, returned to England, and in 1477 had a press at Westminster Abbey, where he printed the *Dictes and Sayings of the Phi-*

losophers, a translation by Earl Rivers from the French of Jean de Teonville; it was the first dated typographical work executed in England. Of the 99 works printed by Caxton, all in black letters, from six fonts of type, he edited almost every one and translated 25 of them from the French, Latin, or Dutch. The first illustrated book printed by him was *The Mirror of the World* (1481). His patrons included Edward IV, Richard III, Henry VII, Margaret Beaufort, and the chief noblemen and merchants of the day. Besides the books already mentioned, Caxton printed Geoffrey Chaucer's *Canterbury Tales*; *Troilus and Criseyde*; *Book of Fame*; John Gower's *Confessio Amantis*; works by John Lydgate; Sir Thomas Malory's *King Arthur*; *The Golden Legend*; and *The Fables of Aesop*. His books have no title pages, but are frequently provided with prologues and colophons. His types were copied so closely from the handwriting of his time that many of his books have been mistaken for manuscript. In some no punctuation is used; in others, the full point and colon only; commas are represented by a long or short upright line. In his introductions he declared that his aim was the creation of a prose style that should do for English prose something akin to what Chaucer had done for English verse. His trade device was a square block with the initials W. and C. intersected by figures representing 1474, with a border at the head and foot. Wynkyn de Worde (q.v.) was his foreman and successor. A memorial tablet is in St. Margaret's Church, Westminster, where he was buried.

CAXTONS, The, a novel by Edward G. E. Bulwer-Lytton (q.v.), published in 1850. *The Caxtons* was not only instantly popular in Britain, but 35,000 copies were sold in the United States within three years after its publication. Never before had Bulwer-Lytton written with so light a touch and so gentle a humor, and this novel has been called the most brilliant and attractive of his productions.

CAYAMBE, kă-yăm'bă, a volcanic peak in the Andes Mountains, lying directly under the equator in northern Ecuador. It rises in the shape of a beautiful and regular cone to a height of 19,160 feet. Its top is crowned with perpetual snow, and its geographical position and great elevation render it one of the most striking mountains of the world.

CAYENNE, ki-ën', city and capital of French Guiana. It is situated on the northwest coast of Cayenne Island (30 miles in circumference), which is formed by the Cayenne River, a small stream that divides into two channels before emptying into the Atlantic Ocean. The harbor is shallow, and vessels drawing over 14 feet have to anchor in the roadstead. Because of the humidity and the low and swampy character of the surrounding region, the climate is unwholesome for white people. The main highway of French Guiana connects Cayenne with Saint Laurent du Maroni, a seaport near the mouth of the Maroni River. Between 1604 and 1652 the French government sent six expeditions to Cayenne and neighboring points on the coast of Guiana. In 1654 the Dutch occupied the settlement at Cayenne, but were obliged to surrender it to a new French expedition in 1664. After the Treaty of Breda in 1667, Cayenne was attacked and damaged by the Brit-

ish, and in 1676 it again was seized by the Dutch; the latter were evicted the same year, and since then it has remained in French possession. Many of the inhabitants of Cayenne are descendants of criminals liberated from the penal settlement which was maintained in French Guiana from 1852 to 1946. Pop. (1946) 11,704.

CAYENNE PEPPER. See **CAPSICUM**.

CAYES, Les. See **AUX CAYES**.

CAYEY, kă-yě'ê, town, Puerto Rico, located in the southeastern part of the island 9 miles north-northwest of Guayama. It is 2,300 feet above sea level, and because of its cool climate it is a favorite summer resort. The town contains old barracks which date from the Spanish colonial period. Coffee, sugar, and tobacco are grown in the surrounding area. The tobacco is considered to be the finest produced in Puerto Rico, and the manufacture of cigars is the principal industry of Cayey. Pop. (1950) 18,429.

CAYLEY, kă'li, Arthur, English mathematician: b. Richmond, Surrey, Aug. 16, 1821; d. Cambridge, Jan. 26, 1895. He received his early education at Blackheath and King's College, London, passing subsequently to Trinity College, Cambridge, which elected him a fellow in 1842 and re-elected him in 1875. Called to the bar in 1849, he practiced for some years as a conveyancer, but in 1863 was appointed first Sadlerian professor of pure mathematics at Cambridge; he continued to occupy this chair until his death. He received many distinctions from universities and learned societies both at home and abroad, and in 1883 he presided over the meeting of the British Association at Southport. He seldom identified himself with movements outside his own immediate work, but took a prominent part in the movement for the higher education of women, which resulted in the foundation of Newnham College. His chief memoirs deal with differential equations, elliptic functions, and determinants. He discovered the higher curve named for him, and the principal proposition of matrices known as Cayley's Theorem. His *Elementary Treatise on Elliptic Functions* appeared in 1876, and *Single and Double Theta Functions* in 1881; a collected edition of his papers (over 900 in 13 volumes) was published between 1889 and 1898.

CAYLEY, Sir George, English inventor: b. Scarborough, Yorkshire, England, Dec. 27, 1773; d. there, Dec. 15, 1857. After education in schools at York and Nottingham, he began studies in chemistry and electricity under George C. Morgan. He made his first experiments in aeronautics at this time, and in 1796 built a tiny helicopter with windmills made of feathers which spun around a vertical axis.

From his observations of bird flight he gained an understanding of natural flight, concluding that flying was feasible for man with the aid of a gliding machine powered by a suitable engine. In 1804-1810 he engaged in aerodynamic experiments, his first published article in 1807 discussing the problem of the engine and outlining his "expansion air engine" which would operate by the expansion of hot air.

By 1809 he was able to explain the problem of flight as "to make a surface support a given weight by the application of power to the resist-

ance of air." He was the first to attempt a mathematical explanation of the basic principles of flight, his essay *On Aerial Navigation* laying the groundwork for the whole science of aerodynamics as it later developed. Articles in 1809-1810 described all his experiments and he referred in these writings to the internal-combustion engine and streamlining. In 1815 he became interested in navigable balloons. In 1837 he patented his hot-air engine, and in 1840 suggested the possibility of a twin-rotor, steam-powered helicopter.

CAYLUS, *kā-lūs'*, COMTE DE (ANNE CLAUDE PHILIPPE DE TUBIÈRES, *tū-byār'*), French archaeologist and man of letters: b. Paris, France, Oct. 31, 1692; d. there, Sept. 5, 1765. He was a son of the Comtesse de Caylus (q.v.), and after serving in the army during the War of the Spanish Succession he left the service in 1715. During 1716 he traveled in Greece and Asia Minor, making some attempts to locate ancient Troy. In 1717 he returned to Paris and began his great work *Recueil d'antiquités égyptiennes, étrusques, grecques, romaines, et gauloises* which was published in seven volumes from 1752 to 1767.

He became an active member of the Academy of Painting and Sculpture and of the Academy of Inscriptions. A friend of Jean Watteau and other contemporary figures of the art world, Caylus himself was a skillful engraver who produced many plates, copying the work of great artists and helping to preserve some early masterpieces.

Between 1749 and 1755 he made extensive experiments in the ancient method of encaustic painting, his *Mémoire* (1755) being a description of the process which he claimed to have rediscovered.

CAYLUS, COMTESSE DE (MARIE MARGUERITE LE VALOIS DE VILLETTE DE MURÇAY, *lê vâ-lwâ' dē vè-lêt' dē mūr-sā'*), French writer of memoirs: b. Poitou, France, 1673; d. Paris, April 15, 1729. Born a Protestant, she was converted to Catholicism by her aunt, Madame de Maintenon. She married the Comte de Caylus in 1686 and was left a widow in 1704. From 1707 until 1715, when Louis XIV died, she was a favorite at the French court, and her *Souvenirs*, written in later years, describes events and personalities at the court during that period.

CAYMAN ISLANDS, *kā-mān'*, a group of three islands in the British West Indies in the northwest Caribbean Sea from 150 to 200 miles west-northwest of Jamaica of which they form a dependency. Occupying an area of approximately 105 square miles, the group consists of Grand Cayman, Cayman Brac, and Little Cayman. The capital is Georgetown on Grand Cayman (pop. 1950 est., 5,721). The mean annual temperature is 80°F. and the heaviest rains occur in September and October.

The chief occupations of the islands are shark and turtle fishing, shipbuilding, rope-making, lumbering, and coconut growing. Roads suitable for motor traffic connect the settlements on the larger islands and all parts of Grand Cayman and Cayman Brac have telephone communication. A system of free and compulsory education has been established. In 1950 there were 16 schools (13 government elementary; 3 private).

The islands were discovered by Columbus on May 10, 1503, and were first named Las Tortugas because of the abundance of turtles. They were

never occupied by the Spaniards, the chief settlement being from Jamaica in the 18th century. Government is by commissioner, assisted by a 53-member Legislative Assembly of justices of peace and vestrymen. The governor of Jamaica approves all laws passed by the local legislature. Pop. (1950 est.) 7,393.

CAYUGA, *kā-yōō'gā* ("place where the locusts were taken out," or "place where the boats were taken out"), tribe of North American Indians which spoke an Iroquoian dialect. One of the original members of the Five (after 1722, Six) Nations Iroquois, the Cayuga were considered younger "brothers," "offspring," or "nephews" of the Mohawk, Onondaga, and Seneca tribes in the social and political structure established by their league. When visited by Jesuit Father Menard in 1653, their villages were located between Owasco and Cayuga lakes in Cayuga County, New York. Later villages were west of Lake Cayuga and on branches of the Susquehanna after the defeat of the Andaste in 1675. A probable offshoot of the Seneca, the Cayuga adopted remnants of such defeated tribes as the Huron, Andaste, Catawba, Delaware, and Illinois.

The basic unit of Cayuga society was the family. The families were grouped into clans, and marriage was not permitted within the same clan. Clans functioned as units in politics and religion. Cayuga villages were moved to new sites when game or fish migrated, soil in the garden became exhausted, or danger of enemy attack impended. Theirs was a typical Iroquoian economy. Maize, squash, and beans, raised by the women in communal gardens, were supplemented by meat and fish taken by the men. During the Revolution the Cayuga sided with the British. Many fled to Canada when Major General John Sullivan burned their villages in 1779. As a result of the treaties of 1789, 1795, and 1803, the Cayuga ceded all their lands to the State of New York. Since 1803 they have lived with other tribes, but have maintained a separate identity. In 1953 they resided as follows: 1,100 in Canada (approximately 1,000 on the Six Nations Reserve); 38 with the Seneca on the Cattaraugus Reservation in New York; 137 scattered on other reservations and in cities. A small number, which formerly lived in Ohio, is in Oklahoma. These were incorporated with the Seneca as Seneca Cayuga in 1937 under the Oklahoma Indian Act and are considered Seneca, although some continue to speak Cayuga. See also SIX NATIONS OF THE IROQUOIS.

GEORGE S. SNYDERMAN.

CAYUGA LAKE, *kā-ōō'gā; kā-yōō'gā; kī-ōō'gā; kū'gā*, lake, New York, on the boundary of Cayuga and Seneca counties, and extending south into Tompkins County. It is the second largest of the Finger Lakes, its area being about 66 square miles. Forty miles in length, it is the longest in the lake group, and has an average width of two miles. Its greatest depth is about 435 feet. At its north end it is connected by the Seneca River with Seneca Lake to the west. The river is partly canalized as a section of the New York State Barge Canal system and is known as the Cayuga and Seneca Canal.

The lake is of glacial origin and drains north to Lake Ontario by way of the Seneca and Oswego rivers. Its high clifflike banks have been cut by the adjoining streams. The surround-

ing area is devoted to farming, fruitgrowing, and resorts.

CAYUSE, kī-ūs', **CAILLOUX**, **CA-JOUSES**, or **KAGOUSE**, American Indian tribe belonging to the Shahaptian stock, speaking a Waiilatpuan dialect, and residing formerly around the Wallawalla, Umatilla, and Grande Ronde rivers, and from the Blue Mountains to the Deschutes River in Washington and Oregon. Spanish explorers in 1592 were the first whites to have contact with the Cayuse. Members of English trading companies came later. The first recorded contact was made by Lewis and Clark in 1806. With the opening up of the Oregon Trail to California and westward emigration for gold after 1850, the Cayuse were soon overwhelmed by white settlers. They suffered severe dislocation, and friction with whites soon began to undermine their strength. Epidemics decimated them numerically and Marcus Whitman, a missionary who established there in 1838, was blamed for these ravages. He and his entire mission were massacred in 1847.

In 1851 the Cayuse partially merged with the Nez Percés and in 1853, as the result of a treaty, they were moved to the Umatilla Reservation. In 1937 the Cayuse numbered 370; because of intermarriages this number is not reliable. Their language is nearly extinct. Horses were early bred among them as a result of their Spanish contact. This particular breed became known as the cayuse.

GEORGE S. SNYDERMAN.

CAZALES, kà-zà-lès', **Jacques Antoine Marie de**, French politician: b. Grenade, Department of Haute-Garonne, France, Feb. 1, 1758; d. Rennes, Department of Ille-et-Vilaine, Nov. 24, 1805. The son of a counsellor of the Toulouse Parliament, Cazalès served for some time in a cavalry regiment as a captain. Being chosen in 1789 a deputy of the nobility to the States-General, he became one of the most able and eloquent opponents of the French Revolution. With Mirabeau he tried to form a party uniting conservatives and liberals who wanted reform without revolution. The Royalists, however, received with ingratitude his efforts on their behalf. Upon the outbreak of the Reign of Terror in 1792 he became an émigré, fighting in an émigré army against the revolution and living in Switzerland and England. He returned to France in 1803, and Napoleon conferred on him the cross of the Legion of Honor.

CAZALIS, kà'-zà-lès', **Henry** (pseudonyms **JEAN CASELLI**; **JEAN LAHOR**), French physician and poet: b. Cormeilles-en-Parisis, Department of Seine-et-Oise, France, March 9, 1840; d. Geneva, Switzerland, July 1, 1909. In 1865, under the name Jean Caselli, he published *Chants populaires de l'Italie* and *Vita tristis, rêveries fantasques, romances sans musique*. Under his own name came *Melancholia* (1868), *Livre du néant* (1872), and *Henri Regnault, sa vie et son oeuvre* (1872). Using the name Jean Lahor, he published *L'Illusion* (1875-1893), a collection of pieces most characteristic of his work. They reveal the influence of his Oriental studies and his enthusiasm for the styles of the Parnassian school of French poets. He also wrote the remarkable *Histoire de la Littérature Hindoue*, and several treatises on medical subjects.

CAZALLA DE LA SIERRA, kâ-thâ'lyâ thâ lâ syér'râ, commune, Province of Sevilla, Spain; about 40 miles north-northeast of the city of Seville; on the south slope of the Sierra Morena in southwestern Spain. It is a food processing and agricultural center, and the chief industries are liquor distilling and manufacture of furniture and wooden boxes. There are mineral springs, and near the city are foundries for the iron and other mineral deposits lying at hand. Pop. (1941) 10,058.

CAZAMIAN, kâ-zâ-myân', **Louis**, French scholar: b. Saint-Denis, Réunion, April 2, 1877. In 1900 he graduated from the École Normale Supérieure, Paris, with a degree in English, and received his doctorate of letters in 1903. He lectured at several French universities and became professor of modern English literature and civilization at the Sorbonne in 1909. He has also lectured at the University of California, Rice Institute (Houston, Texas), Columbia University, and Wellesley College. Among his published works translated into English are *Modern England* (1911); *Carlyle* (1914); *History of English Literature* (with Émile Legouis, q.v., 1927; 8th ed., 1947); and *The Development of English Humor*, part 1 (1930); part 2 (1952).

CAZEMBE, kâ-zêm'bě, former Negro state in Africa occupying the area which later became the most northern part of Northern Province, Northern Rhodesia.

The kingdom developed as the result of conquests by a Bantu-speaking people during the 16th century. The conquering tribal divisions expanded eastward from what is now southwestern Belgian Congo to Lake Mweru, and created an empire whose sovereign bore the title muata yamvo. In the 17th century the area bounded by Lakes Tanganyika, Bangweulu, and Mweru was subjugated, and Cazembe became one of the kingdoms established; it was named for its ruler, Muata Cazembe.

Ivory trade with Arabs and Portuguese and rich copper mines enriched the kingdom. The population was divided into two distinct classes: the ruling race who had invaded and conquered the country; and the original inhabitants who were regarded as a servile class. The earliest recorded visit by a European was made by Manoel Pereira, Portuguese merchant, in 1796. Francesco de Lacerda in 1831 and David Livingstone in 1868 explored the area. About 1875 a usurper overthrew the muata and the kingdom declined rapidly thereafter.

CAZIN, kâ-zân', **Jean Charles**, French artist: b. Samer, Department of Pas-de-Calais, France, May 25, 1841; d. Le Lavandou, Department of Var, March 27, 1901. He was educated at the college in Boulogne and then went to Paris, where he studied art under Paul Le Coq de Boisbaudran. In 1868 he was appointed director of the École des Beaux-Arts and conservator of the museum at Tours. In England from 1871 to 1874, he was influenced by the Pre-Raphaelites. During 1874-1875 he was in Italy, and in 1876 he exhibited his *Le Chantier*. The following year came *La Fuite en Egypte* and in 1878 *Le Voyage de Tobie*. In 1880 he showed *Le Départ de Tobie*, *La Terre*, and *Ismaël et Agar*, the last bringing Cazin recognition as a master of landscape-religious painting.

For his *La Terre*, based on an Adam and Eve

theme, he obtained a medal of the first class. Other works are *Souvenir de fête*; *Poste de secours*; *Judith* (1883); and *La Journée faite*, in which he departs from the religious theme to portray a scene of contemporary reality. He is well known as a landscape painter. His figures are always subservient to the scene. But he has a power of idealization which gives to truth the most delicate air of poetry, a tender melancholy and charm. A wistful, hushed, sympathetic note pervades his works. He attempted to revive the art of encaustic painting. He became a member of the Legion of Honor. He also completed the decorations on the Puvis de Chavannes in the Pantheon (1898). Consult his biography by Bénédite (Paris 1901); and Marcel, *La Peinture française au XIXe siècle* (Paris 1905).

CAZORLA, kâ-thôr'lâ, Spain, a town in Andalusia and 41 miles east of the city of Jaen. It rises in the form of an amphitheatre on the slope of the Sierra de Cazorla, and is well built, though much less important and populous than in the time of the Moors, during whose wars it held an important position. It has two castles, both in good preservation. The Sierra de Cazorla is a wooded ridge round which winds the upper course of the Guadalquivir. Pop. 7,936.

CAZOT, kâ-zô', Théodore Joseph Jacques, French politician: b. Alais, Feb. 11, 1821; d. 1912. In 1848 he was active as a Republican in his home department; in 1870 he was appointed general secretary in the ministry of the interior; in 1871 elected to the National Assembly; and in 1875 was made life senator. From 1879-1882 he was Minister of Justice and was interested in bringing about a reform in the appointment of judges, but retired without passing the law he desired. In this capacity he was also active in the persecution of the Jesuits and other unauthorized assemblies. In 1883 he was president of the Court of Cassation, resigning in 1884 on account of being implicated in fraudulent dealings.

CAZOTTE, kâ-zôt, Jacques, French poet: b. Dijon, 1720; d. Sept. 25, 1792. His masterpieces are *Olivier* (1762), a poem of chivalry after the manner of Ariosto; and *The Devil in Love* (1772), a tale of wonder, still a popular favorite. He had extraordinary skill in versifying, as shown by his adding a seventh canto to Voltaire's *Civil War of Geneva* with such perfect imitation of Voltaire's style and manner as to deceive all Paris. He joined the *Illuminati* about 1775. For his opposition to the Revolution as a Royalist he was guillotined by the Revolutionary Tribunal. Consult De Nerval, *Illuminés* (Paris 1852).

CAZWINI, kâz-wē'nē, Zacharia Ben Mohammed, Arabian naturalist: b. Cazwin, Persia, 1212; d. April 7, 1283. He was descended from a family of lawyers, who derived their origin from Anas Ben Malek, a companion of Mohammed, and had settled in Cazwin, a city in Persia. From that place this author received the surname under which he has become celebrated. Of the circumstances of his life we know little more than that he was cadi of Wazith and Hillah, and died in the year of the Hegira 682 (1283 A.D.). His most im-

portant work is on natural history—*The Wonders of Nature and the Peculiarities of Creation*—of which Ideler, professor in the University of Berlin, published the chapter on the *Constellations of the Arabians*, and of which there are fragments in Bochart's *Heirozoikon*, in Ouseley's *Oriental Collections*, and in Wahl's, Jahn's and De Sacy's *Arabic Chrestomathies*. It was the object of Cazwini, like Pliny, to describe the wonders of all nature. His work contains a comprehensive view of all that had been written before him, but in so grand and original a manner that it is of higher value than most of the original works which treat of the same subjects. There is an abridged translation of it in the Persian.

CEAN-BERMUDEZ, thâ-ân' bër-moo'-dâth, Juan Agustin, Spanish art historian and painter: b. Gijon, Asturias, Sept. 17, 1749; d. Madrid, Dec. 3, 1829. He devoted himself early to the study of the fine arts, into which he was initiated by Raphael Mengs. After holding a public office at Madrid, he retired to Seville, where he founded an academy of fine arts, and occupied himself with the study of their history. He was elected a member of the royal academies of history and fine arts at Madrid, and published several valuable works connected with his favorite pursuits. His most important book, entitled *Sumario de las anti-gueda des romanas que hayan España*, appeared posthumously in 1832. He published also *Diccionario histórico de los más ilustres profesores de las bellas artes en España* (1800); *Descripción artística de Sevilla* (1804); *Diálogo sobre el arte de la pintura* (1819); *Noticias de los arquitectos y arquitectura de España* (1829).

CEANOTHUS, a genus of shrubs and small trees of the natural order *Rhamnaceae*. There are about 35 species, mostly natives of the Pacific Coast region of North America. They are characterized by serrate or entire simple leaves; small, perfect, white, purplish or blue flowers in showy clusters, which are often paniced; and three-celled drupaceous fruits, which, on drying, separate into three stones. Many of the species and their hybrids are popular ornamental shrubs, especially in mild regions, their free-blooming habit rendering them specially useful as lawn specimens. Three species, *C. americanus*, *C. ovatus* and *C. fendleri*, and some of their hybrids, are hardy in the north, but usually the hybrids must either be protected from frost or stored over winter in a plant-pit or frost-proof cellar. They succeed in almost any soil, but do best in light, well-drained loams, especially when exposed to the sun. Propagation is easily effected by seeds, cuttings or layers. *C. americanus* known as New Jersey tea and red-root, is common from Canada to the Gulf States. Its leaves are said to be used as a substitute for tea, a use to which they are reported to have been put during the American Revolutionary War.

In medicine ceanothus has not been used to any great extent. Its roots contain from 6 to 10 per cent of tannin, and have been used in domestic medicine as astringents. Owing to the close resemblance of the roots, ceanothus has been used as an adulterant for rhatany.

CEARÁ, sâ-â-râ', Brazil, a state bounded on the north and east by the Atlantic Ocean and the state of Rio Grande de Norte, on the

south by Pernambuco, and on the west by Piauí. The area is 57,371 square miles, and the population numbers 2,524,266 (1949 est.) Fortaleza, sometimes called Ceará, is the state capital and principal port; a lesser port is Camocim, 170 miles west-northwest of Fortaleza. Cities in the interior of the state include Sobral and Crato (terminus of a railroad from Fortaleza). The coast regions are sandy and unproductive, while the center is occupied by an elevated plateau which is sparsely watered and fit only for pasture. The climate is hot and dry. The most fertile area is in the upper reaches of the Jaguaribe River. Cotton, coffee, sugarcane, and fruits are cultivated. Irrigation projects have been undertaken. Portuguese occupation of the area dates from 1604, when a settlement was established near Camocim. The province of Ceará was constituted in 1822.

CEBES, sē'bēz, a Greek philosopher, of Thebes, who flourished in the 5th century B.C. A disciple and friend of Socrates and Philolaus, he is one of the interlocutors in the *Phaedo* of Plato, seeking virtue and truth. For long he was reputed to be the author of three dialogues in the Socratic style—the Phrynicus, the Hebdome, and the Pinax, or "votive tablet," a philosophical dialogue representing allegorically the temptations of this life and teaching that true learning can alone make for happiness. In spite of its pure Attic, and its truly Socratic tendency, modern criticism now assigns the work to the 2d century A.D. It was translated into all the languages of Europe, as well as Arabic, which latter version, made possible in the 9th century, is our sole record of the close of the dialogue.

CEBES OF CYZICUS, sīz'ī-kūs, a Greek philosopher, one of the Stoics, who flourished in the 2d century A.D.

CEBIDAE, sēb'ī-dē, in zoology, a family of platyrrhine monkeys. It includes all the monkeys found in the Americas with the exception of the marmoset and the tamarin. See also MONKEY.

CEBU, sā-bōō' (Visayan SUGBU, sōōg-bōō'), island, one of the Visayan Islands, in the east central part of the Philippine Islands. Tañon Strait, on the west, separates it from Negros, and Bohol Strait, on the southeast, separates it from Bohol; on the north it is bounded by the Visayan Sea, and on the east is the Camotes Sea. The island has an area of 1,707 square miles. The province of Cebu comprises that island and several others adjacent, among them Bantayan, west of the northern end of Cebu, and the Camotes group and Mactan, both off the east coast; the province has an aggregate area of 1,880 square miles and population of 1,068,078 (1939 census). The length of the island of Cebu, from northeast to southwest, is 139 miles, and the width is about 20 miles. It has a mountain system consisting of a chain running the length of the island, nearer the east than the west coast. There are six passes, the best of these being the southernmost, from Sibonga, on the east coast 28 miles southwest of the provincial capital of Cebu (q.v.), to Dumanjug, on Tañon Strait, 37 miles southwest of the capital. Other towns, both on the east coast, include Argao and Carcar. The major products of Cebu are coconuts, corn, rice, sugar, and tobacco; gold and coal are mined,

and petroleum deposits have been located. Miguel López de Legazpi (Legaspi) (q.v.) occupied the island in 1565. The Spanish authorities evacuated Cebu in 1898, and civil government was established by the United States in 1901.

CEBU, city, Philippine Islands, capital of Cebu Province, in the central part of the east coast of the island of Cebu (q.v.). It is the oldest Spanish town in the Philippines. In front of Santo Niño Church is the cross said to have been set up by Ferdinand Magellan, discoverer of the island on April 7, 1521. The city was occupied by the Japanese on April 18, 1942; it was recaptured by American troops on March 27, 1945. Pop. (1948) 167,503.

CECCHI, chāk'kē, Giovanni Maria, Italian dramatist: b. Florence, March 15, 1518; d. there, Oct. 28, 1587. The best of his 95 plays are *La Dote*; *Il Servigiale*; *La Stinava*; *La Moglie*. His religious dramas included *L'Esaltazione della Croce* (1580).

CECCO D'ASCOLI, chāk'kō dēs'kō-lē (properly FRANCESCO DEGLI STABILI), Italian poet and philosopher: b. Ascoli, about 1257; d. Florence, Sept. 16, 1327. In 1322 he was appointed professor of astrology at the University of Bologna. He wrote a commentary on the *Tractatus de Sphaera Mundi* of Johannes de Sacrobosco (q.v.) which aroused the hostility of the church. Moving to Florence, he wrote four books of *L'Acerba*, a poem of encyclopedic compass which attacked the *Divina Commedia* of Dante. The subject of the first book was astronomy with meteorology; of the second, stellar influence and physiognomy; of the third, minerals; of the fourth, sundry problems, moral and physical. This work was deemed heretical, and in consequence he was burned at the stake.

CECH, chēk, Svatopluk, Czech poet: b. Ostředek, Feb. 21, 1846; d. Prague, Feb. 23, 1908. After being educated at Prague (Praha) he practiced law, at the same time being editor in succession of several journals. A writer of national poetry, he achieved fame with such poems as *The Dreams* (1872), *The Adamites* (1874), and *Songs of Morning* (1886). His fiction included *Stories Arabesque and Humoresque* and the amusing *Candidate for Immortality* (1884).

CECIL, sēs'il, name of a historic English family. Its known ancestry begins with David Cecil (the name is variously spelled), who became a freeman of Stamford, Lincolnshire, in 1494, and subsequently mayor of that place, a member of Parliament, and sheriff of the county. Richard Cecil, his son, was the father of William Cecil, 1st Baron Burghley (see BURGHLEY), the founder of the family's greatness. From him, through successive wives the family split into two branches. THOMAS CECIL (1542-1623), 1st EARL OF EXETER and 2d BARON BURGHLEY, first of the elder line, fought in Scotland (1573) and the Low Countries (1585), and against the Spanish Armada (1588). SIR EDWARD CECIL (1572-1638), VISCOUNT WIMBLEDON, third son of the 2d Baron Burghley, commanded incompetently in the Low Countries (1596-1610) and led an expedition which negligently permitted Spanish treasure ships to find haven in Cadiz (1625). DAVID GEORGE BROWNLOW CECIL (1905-),

son and heir of the 5th Marquis of Exeter, was Olympic 400-meter hurdles champion in 1928.

ROBERT CECIL (1563?-1612), 1ST EARL OF SALISBURY and 1ST VISCOUNT CRANBORNE, first of the younger line, was the sole surviving son of the 1st Baron Burghley by his second wife. As secretary of state (1596-1608) he conducted the realm's foreign affairs. With the death of Elizabeth in 1603 he was instrumental in calling James VI of Scotland to the throne of England as James I. From 1608 he was lord treasurer.

ROBERT ARTHUR TALBOT GASCOYNE-CECIL (1830-1903), 3D MARQUIS OF SALISBURY, great British statesman, entered the House of Commons as a Conservative in 1853; after succeeding to the marquise in 1868 he was a member of the House of Lords. He served in the Cabinet as secretary for India (1866-1867 and 1874-1878) and for foreign affairs (1878), and in 1881 he was chosen leader of the peers in opposition to the Liberal administration. During 1885-1886, and again from June 1886 until 1892, he was Conservative prime minister and foreign secretary. His second term as premier was the period of the partition of Africa, royal charters being granted to the British East Africa Company (1888) for what became Kenya Colony and to the South Africa Company (1889) for what became the Rhodesias, and agreements being made (1890) with France in respect of Madagascar and with Germany respecting spheres of influence in Africa. From 1892 to 1895 he again led the opposition in the House of Lords. In 1893 the peers, by his advice, rejected William Gladstone's second bill for Home Rule for Ireland. Salisbury's third and last premiership was from 1895 until his retirement in 1902; he was also foreign secretary until 1900. During these years he had to deal with the question of Turkish atrocities in Armenia, United States intervention in the Venezuela-British Guiana boundary dispute, Russia's seizure of ports in Manchuria, a French attempt to establish a post on the Nile at Fashoda, and the South African War.

JAMES EDWARD HUBERT GASCOYNE-CECIL (1861-1947), 4TH MARQUIS OF SALISBURY, was a member of the House of Commons from 1885 until succeeding his father, the 3d marquis, in 1903, when he entered the House of Lords. He was a member of the Cabinet as lord privy seal (1903-1905) and president of the Board of Trade (1905), and in 1911 he was one of the Conservative peers who bitterly opposed the Parliament bill of David Lloyd George curtailing the powers of the House of Lords. During World War I he remained aloof from the coalition governments of Britain. He again served in the Cabinet, as lord president of the council (1922-1923) and lord privy seal (1924-1929). Subsequently, in the House of Lords, he spoke frequently in opposition to Indian constitutional reform. (EDGAR ALGERNON) ROBERT CECIL (1864-), 1ST VISCOUNT CECIL OF CHELWOOD, third son of the 3d Marquis of Salisbury, was a leading barrister before entering the House of Commons in 1906. During World War I he filled posts in the coalition governments, and after the conflict he was associated closely with President Wilson and Gen. Jan Christiaan Smuts in drafting the Covenant of the League of Nations. Under Prime Minister Stanley Baldwin he served as lord privy seal (1923-1924) and chancellor of the duchy of Lancaster (1924-1927); he resigned the latter

seat because the Cabinet failed to support the recommendation of the British delegation to the Disarmament Commission at Geneva (which he headed) that a compromise on the cruiser question should be reached with the United States. He continued to be a staunch supporter of the principles of the League of Nations, and in 1937 he was awarded the Nobel peace prize. Besides the autobiographical *A Great Experiment* (1941), he wrote *The Way of Peace* (1928) and *All the Way* (1949).

HUGH RICHARD HEATHCOTE CECIL (1869-), 1ST BARON QUICKSWOOD, fifth son of the 3d Marquis of Salisbury, was a Conservative member of the House of Commons from 1895 to 1906, and again from 1910 until 1937. A man of independent views, he frequently opposed the policies of his party. As a free trader, he was a leader among those Conservatives who fought the tariff reform policies of Joseph Chamberlain. When the Liberals sought to limit the powers of the House of Lords by enactment of the Parliament bill in 1911, he was one of its unsuccessful opponents. In the House of Commons, in 1928, he strongly supported the Anglican prayer-book proposals. From 1936 to 1944 he served as provost of Eton College. He received a barony in 1941. ROBERT ARTHUR JAMES CECIL (1893-), VISCOUNT CRANBORNE, 1ST BARON CECIL OF ESSENDON, elder son of the 4th Marquis of Salisbury, was a Conservative member of the House of Commons from 1929 until 1941, when he received a barony and was called to the House of Lords. During World War II he served the coalition government under Winston Churchill as paymaster-general (1940), secretary of state for dominion affairs (1940-1942) and for the colonies (1942), lord privy seal (1942-1943) and, once more, as secretary of state for dominion affairs (1943-1945).

LORD (EDWARD CHRISTIAN) DAVID CECIL (1902-), younger son of the 4th Marquis of Salisbury, graduated at Oxford University and subsequently lectured there. In 1948 he was appointed Goldsmith professor of English literature at New College. *The Life of Cowper* (in America, *The Stricken Deer: The Life of Cowper*, 1929) and *The Young Melbourne* (1939) are considered by many to be the finest of his books. Others included *Sir Walter Scott* (1933); *Early Victorian Novelists* (1934); *Jane Austen* (1935); *Hardy, the Novelist* (1943); *Two Quiet Lives* (1948); and *Poets and Story-tellers* (1949).

CECILIA, sê-sîl'i-â Saint, Christian virgin and martyr; her day in the Roman calendar is November 22. Her story as recounted in the *Breviarium Romanum*, represents her as a Roman lady of noble birth, a Christian from childhood, and from her early years vowed to virginity. Yet her parents gave her in marriage to a young noble, Valerianus, whom Cecilia persuaded not only to respect her vow, but also to become a Christian; and he, converted, induced also his brother, Tiburtius, and their intimate friend, Maximus, to enter Christ's fold; shortly after these three suffered martyrdom together. Cecilia now, in anticipation of the same fate or the same crown, distributed her possessions among the poor, and this becoming known to the prefect of Rome, he ordered her to be taken to her own mansion and there burned to death in the bath (*in balneo*). But the virgin, exposed to the flames for a day and a night, was found

unhurt; and, after the axe of the headsman had also failed to sever her head from her body, at last she won the double wreath of virginity and martyrdom; this was in the reign of Alexander Severus and in the pontificate of Urban I, about the year 230. Urban erected a church in her house which was called by her name. The church of Saint Cecilia is still one of the most notable churches of Rome, having been again and again repaired or reconstructed.

In this account of Saint Cecilia nothing is said of the musical accomplishments of the virgin, but legend makes much of them; hence, Saint Cecilia is the patron saint of music and musicians, and musical societies are very commonly called by her name: John Dryden's fine ode, *Alexander's Feast*; a *Song for Saint Cecilia's Day* is an imperishable monument of the Cecilian legend in English literature.

Consult Gueranger, Prosper L. P., *Sainte Cécile et la société romaine* (Paris 1873).

Another Saint Cecilia was born in Africa and suffered martyrdom by starvation under Diocletian. The Roman Catholic Church celebrates her festival on February 11.

CECILIA, a novel by Fanny Burney, published in 1782. It is a typical English novel of a century ago. The plot is simple, the story long drawn out, the style stilted, and the characters alone constitute the interest of the book, and justify Dr. Samuel Johnson's praise of Miss Burney as "a little character-monger."

CECROPIA, *sê-krô'pî-â*, a genus of plants of the order Artocarpaceae of which the best known species is the trumpetwood (*C. peltata*) of the West Indies and tropical South America. It attains a height of about 50 feet, and has a hollow stem and branches, from which musical instruments are made. Its leaves are very large, circular and peltate, and serve as food for sloths; and its flowers are small and grouped in short spikes, several of which are enclosed at first in a large bract. The wood is light and soft, and is employed by the natives in various ways, particularly for the purpose of obtaining fire by friction. Ropes are made from the inner bark, and the outer bark has astringent properties. Caoutchouc is obtained from the juice, and the buds are employed as a potherb. Certain ants utilize the hollow stem as dwellings and prove their value by repelling attacks on the trees of leaf-cutting ants.

CECROPIA MOTH, a colossal species (*Samia cecropia*) of the silkworm family Saturniidae, which ranges over eastern United States to the Rocky Mountains. The moth expands five or six inches and is brick red in color, the wings tinged with grizzly, each wing with a large crescent-shaped spot near the center, which is red and white, or white edged with red and black; on the apex of each fore wing is a large, black, eye-like spot. The caterpillar is a large green worm three to four inches in length, protected by large tubercles colored green, blue, yellow, or red. It is not uncommon on the elder, willow, apple, currant, pear, thorn, or poplar tree. At the end of summer it spins a large cocoon, open at one end, and attaches it to a branch of a tree. Allied species are found in northern Maine and Canada, Colorado and Wyoming, and on the Pacific Coast.

CECROPS, *sê'krôps*, according to Greek tradition, the founder of Athens, and the first king of Attica. He was said to have been an autochthon (sprung from the soil), and was sometimes represented as half man, half dragon. He taught the savage inhabitants religion and morals, made them acquainted with the advantages of social life, and laid the foundation of the future city of Athens, which after him was originally called Cecropia. According to later legend, he was responsible for the formation of a confederacy of 12 cities, the introduction of marriage, burial of the dead, writing and other arts. He is also said to have introduced the art of shipbuilding. He died after a reign of 50 years. By the later Greeks he was represented as having led a colony to Attica from Sais in Egypt about 1400 or 1500 B.C., but the best modern critics do not look upon this event nor on the life of Cecrops at all as historical. There is no doubt that Egypt did have a certain influence on the development of civilization in Greece, but how great this influence was, or in what manner exercised, history does not furnish sufficient data to enable us to decide. It is probable that the true Cecrops was a hero of the Pelasgian race.

CEDAR, *sê'dêr*, the name of two rivers: (1) a river rising in the extreme southern part of Minnesota, which flows southeast through the eastern part of Iowa by way of Waterloo, Vinton, and Cedar Rapids to Muscatine County, where it turns southwest and flows into the Iowa River at Columbus Junction, after a course of 329 miles; (2) a river rising in Garfield County, Nebraska, which flows 120 miles southeast into the Loup River at Fullerton, in Nance County.

CEDAR, various cone-bearing evergreen trees and their wood; also several nonconiferous trees. The most widely known are probably the cedar of Lebanon (*Cedrus libani*), the deodar, or god-tree, of India (*C. deodara*), and the African or Atlas cedar (*C. atlantica*). These are large ornamental evergreen trees with wide-spreading branches, which give them a form distinct from most other cone-bearing trees. They are sometimes planted in southern California and the Gulf states, and the last-mentioned species even as far north as Philadelphia, where it can stand the winter in sheltered situations. They are readily propagated by seeds, and thrive in well-drained, loamy soil. From ancient times their odorous, light red wood has been used for fine furniture and interior house finish. The white gum of the cedar of Lebanon, which oozes from the trunk and branches, was formerly employed in embalming, but the forests of this tree have become so much reduced that neither the resin nor the oil made from it are in commerce. The other species are most abundant, the deodar in India and the Atlas cedar in northern Africa. Their timber is widely used for fine cabinet work.

The red cedar (*Juniperus virginiana*) is a well-known very variable tree found from Canada to Florida, and westward to the Great Plains. It attains a height of about 80 feet; has a conical more or less spreading head with upright limbs; evergreen, spiny, pointed leaves, and bluish globular fruits covered with bloom. The white cedar (*Chamaecyparis thyoides*) is also a well-known American tree found in wet ground from New Hampshire to Florida. It attains a height of 70 to 80 feet; has erect spreading branches, thin and

flat pendulous twigs, fragrant green leaves, and tiny bluish-purple cones covered with bloom. The trees are highly ornamental, and, being hardy, are general favorites in the North. The wood is especially useful in moist places. The name white cedar is often applied to the arbor vitae (*Thuja occidentalis*). The yellow cedar (*Chamaecyparis nootkatensis*), a common tree on the Pacific coast from Oregon to Alaska, is valued, in cabinet work and interior house-finishing, for its light yellow wood, which takes a high polish. Like its relative mentioned above, it is often planted for ornament. In its home it often exceeds 100 feet in height. The best known nonconiferous trees that are sometimes called cedar are probably *Cedrela odorata*, the West Indian or Spanish cedar, and *Cedrela toona*, the Australian cedar. See TOON; JUNIPER.

CEDAR APPLES, fungous outgrowths upon juniper and red cedar trees. They are caused by some species of the parasitic fungus, gymnosporangium, one of the rusts. At the first they appear like warts upon the smaller branches and twigs, becoming chocolate color or brown as autumn advances, and remaining attached and unchanged until spring, when they enlarge into horn-shaped, jelly-like masses that resemble sponge. At this time they produce their abundant spores which, as the masses become dry, are blown away by the wind and, alighting on apple-trees, produce rust on the foliage and other green parts. They will not germinate upon cedar or juniper, but require an alternate host, the apple, to complete their life cycle. For methods of control see APPLE; FUNGICIDE.

CEDAR CITY, city, Utah, in Iron County; altitude 5,840 feet; it is served by the Union Pacific Railroad and has a modern airport and bus service. Situated 189 miles north of Las Vegas, Nevada, and 220 miles southwest of Salt Lake City, Utah, the city, in the heart of scenic southern Utah, serves as the gateway to Utah's national parks and monuments. Cedar Breaks National Monument and Bryce Canyon National Park are to the east and Zion National Monument and Zion National Park to the south.

Cedar City is situated in a large livestock and agricultural area. Industries include brickmaking, concrete products, coal and iron mining, feed mills, creameries, seed raising, bottling, canning, meat packing, and produce raising.

Educational and Cultural Facilities.—The city has a public library; a modern school system with high schools and gymnasium; and a hospital. There are a number of churches of the Latter-day Saints; also a Presbyterian and a Catholic Church. Cedar City is the home of the Branch Agricultural College, founded 1897, which offers the bachelor's degree, and a summer school for students interested in advanced work in higher education. The Music Arts Association fosters community renditions of music. Exhibitions of paintings and other art forms are continuous in addition to annual showings. Recreation is provided for in the operation of a municipal swimming pool, riding stables, softball games, tennis courts, golf course, skiing, boating, hunting, and fishing.

History.—Cedar City was founded in 1851 by Mormon colonists sent out by Brigham Young to discover suitable sites for colonization. They also discovered beds of iron ore. A volunteer group

of settlers skilled in mining and smelting was organized, and it was here that iron was first refined west of the Mississippi River. With the advent of the Union Pacific Railroad (1923), iron ore production in the vicinity rose materially. The vast iron deposits west of Cedar City supply ore for all the smelting plants in Utah, and also supply ore to plants in California and Colorado.

Cedar City was incorporated Feb. 18, 1868. Its form of government is by mayor, city manager, and city council. Pop. (1950) 6,106.

CEDAR CREEK, Battle of. After the battle of Fisher's Hill, Va., Sept. 22, 1864, Gen. Philip H. Sheridan followed Gen. Jubal A. Early as far as Harrisonburg, his cavalry going as far as Port Republic, Staunton, and Waynesboro, Virginia. In view of the difficulty of supplying his army so far from its base, and of other operations by which two corps of infantry and a cavalry division of his army were to be sent to the Army of the Potomac, he holding only the lower valley of the Shenandoah, Sheridan, after ordering the destruction of all mills, barns, grain, forage, and provisions of all kinds, began to withdraw down the valley on October 5, and on the 8th recrossed Tom's Brook. His rear had been so persistently followed and harassed by Confederate cavalry that he ordered his cavalry commander to whip them or be whipped. On the morning of the 9th they were engaged and routed, and 300 Confederates were taken prisoner with 11 guns and 40 wagons.

Sheridan then resumed his march, and on the 10th halted on the north bank of Cedar Creek. He was followed by a Confederate Army of about 18,000 men under General Early, who arrived at Fisher's Hill, six miles from Cedar Creek, on October 13. Sheridan departed for Washington, leaving Gen. H. G. Wright in command of the Union Army which numbered about 31,000 men. Reconnaissance parties wrongly reported that Early had retreated from Fisher's Hill. Counter Confederate reconnaissance disclosed the fact that the Union line was lightly picketed, and that infantry could cross the creek secretly by night and advance to within half a mile of the Union lines. A comprehensive plan of attack was worked out by Early, and the movement began after dark on the 18th. At dawn of October 19, covered by darkness and fog, the Confederate attack surprised the Union camp, swept everything out of it and turned captured guns upon the fugitives. Other concurrent attacks, parts of the plan, were equally successful. Wright, who had foreseen at the beginning of the attack that his position was untenable, and a change of front was necessary, withdrew to more tenable positions. Following up their advantage in spite of stiff resistance, the Confederates pressed forward, and Wright withdrew to a position north and west of Middleton, Va., where he was reinforced, and prepared to counterattack as soon as a supply of ammunition could be issued.

Sheridan, returning in haste, approved Wright's redistribution of his troops. A further attack along the entire line by Early was repulsed, and the Confederates retired to Fisher's Hill where a defensive line was thrown up beyond the reach of Union artillery. Sheridan ordered a general advance which, after a severe and obstinate fight during which parts of the Union line were repulsed, proved successful. The Confederate line was broken and the entire

army fled in disorder pursued by Union cavalry. The 24 guns taken by Early were recaptured, and he left in Sheridan's hands 23 of his own. The Union loss was 644 killed, 3,430 wounded, and 1,591 missing; of the latter 1,429 were sent as prisoners to Richmond. The Confederate loss was 320 killed, 1,540 wounded, and 1,050 missing. Early's offensive movement suspended for a time the transfer of any part of Sheridan's army to the Army of the Potomac; his defeat ended Confederate efforts to invade the North by way of the Shenandoah Valley. See also **SHENANDOAH VALLEY, MILITARY OPERATIONS IN**.

E., *Shenandoah Valley in 1864* (New York 1883); The Century Company, *Battles and Leaders of the Civil War*, vol. 4 (New York 1884-1887); Sheridan, P. H., *Personal Memoirs* (New York 1888); Ashby, T. A., *The Valley Campaigns* (New York 1914).

CEDAR FALLS, city, Iowa, in Black Hawk County; altitude 854 feet; on the Cedar River, and served by the Chicago Great Western; the Chicago, Rock Island and Pacific; the Illinois Central; and the Waterloo, Cedar Falls and Northern railroads. It is six miles west of Waterloo. Situated in an agricultural area, the chief manufactures include farm tools and equipment, pumps, concrete mixers, overhead doors, humidifiers, highway flares, brooms, seed-processing machinery, and stock feed.

The city has a public library, and is the seat of the Iowa State Teachers College (founded 1876), on the campus of which is a 100-foot campanile. First settled in 1844, Cedar Falls was successively incorporated as a village, a town, and, in 1865, as a city. Its government is by a mayor and council. The water-supply system is municipally owned. Pop. (1950) 14,334.

CEDAR KEYS, city, Florida, in Levy County; altitude 13 feet; on an island in a group of the same name in the Gulf of Mexico, south-southeast of the mouth of the Suwannee River; 58 miles southwest of Gainesville, connected with the mainland by a 3-mile causeway. A railway in 1860 made this town for a time a transshipping point for southern Florida, and there was a customhouse here. When the railroad was abandoned, commercial fishing, oyster and sponge gathering, and palmetto fiber brush factories became the leading industries. Pop. (1950) 900.

CEDAR KEYS, small group of islands situated approximately at longitude 83° W. latitude 29° 7' N., in the Gulf of Mexico, off the northwestern coast of the Florida peninsula, Levy County. Indian burial mounds have been excavated here. Some of the islands are government bird sanctuaries.

CEDAR LAKE, lake, Canada, in western Manitoba, northwest of Lake Winnipeg. It is 40 miles long, 32 miles broad at its widest point, and has an area of 285 square miles. The Saskatchewan River flows through it from west to east, and then pours over the Grand Rapids into Lake Winnipeg. Cedar Lake is deep enough for the largest craft except at the northwest where alluvium is deposited by the Saskatchewan. Both the surrounding mainland and the islands are well wooded with balsam, spruce, birch, poplar, tamarack, pine, and cedar, the last growing on the shores of the lake, particularly the northwest, from which the lake derives its name.

CEDAR MOUNTAIN, CEDAR RUN, or SLAUGHTER'S MOUNTAIN, Battle of. On Aug. 8, 1862, Gen. S. W. Crawford's brigade of Maj. Gen. N. P. Banks' corps marched from Culpeper Courthouse to Cedar Run to support Gen. G. D. Bayard's cavalry brigade which was being driven back by Stonewall Jackson. The latter, with the three divisions of C. S. Winder, R. S. Ewell and A. P. Hill, in all nearly 24,000 men, was advancing from Gordonsville to seize Culpeper. Next day Banks' entire corps, at Little Washington, was ordered to follow Crawford, and Gen. Franz Sigel was ordered to march his corps from Sperryville to the same point. Banks joined Crawford at Cedar Run about noon and took position on elevated ground just beyond it, covering the road to Culpeper; Crawford's brigade, and six companies of Wisconsin infantry, of Gen. G. H. Gordon's, on the right of the road, being partially hidden in woods. Gordon's brigade was held in reserve on the nearer side of the stream. Across the road on Crawford's left was Gen. J. W. Geary's brigade; Gen. Sterling G. Prince's brigade was on Geary's left, and G. S. Greene's small brigade to the left of Prince and somewhat removed. Seven batteries of artillery were distributed on the plateau slightly in advance of the infantry. Banks had about 8,000 men. Jackson, having crossed the Rapidan August 8, about noon of the 9th drove back Bayard's cavalry, and following, came under Union artillery fire and prepared for battle. Early's brigade was ordered to advance, keeping to the right and close to the Culpeper road, while Ewell led his two other brigades further to the right along the slope of Cedar Mountain. Early advanced and, coming under severe artillery fire, halted under cover of a small hill; C. S. Winder's division and three batteries came up on his left. Col. W. B. Campbell's brigade on the extreme left, then Gen. W. B. Taliaferro's, with Winder's brigade in reserve. While placing his batteries in position, Winder was mortally wounded by a piece of shell. At 5 o'clock, August 9, Banks gave the order to advance and attack. After skirmishing actions, the main line became severely engaged. The battle surged back and forth, each side advancing and suffering rebuffs. It was going hard with Early when reinforcements came up and permitted him to restore the fight and check further Union advances. Union reserves, called into action, suffered heavy loss and fell back. The Confederate advance continued. Night had now fallen, but Jackson, desiring to enter Culpeper before morning, gave immediate pursuit, and when one and one-half miles from the field was checked by Banks' rallied troops and Gen. James B. Rickett's division, which had come up from near Culpeper, followed later by Sigel. Meantime, Brig. Gen. John Pope had arrived and assumed command. Pope and Jackson confronted each other on the 10th and the 11th, but, on the night of the 11th, Jackson retreated, abandoning many of his wounded, recrossed the Rapidan and marched to the vicinity of Gordonsville. The Union loss was 1,759 killed and wounded, and 594 missing. The Confederate loss was 1,338 killed and wounded, and 31 missing.

C., *The Army under Pope* (New York 1881); The Century Company, *Battles and Leaders of the Civil War*, vol. 2 (New York 1884-1887); Allan, W., *Army of Northern Virginia in 1862* (Boston 1892); *Official Records*, vol. 12 (Washington, D.C., 1881-1901).

CEDAR MOUNTAINS (Du. CEDER BERGEN, kã'dër bër'gë), a mountain range in the province of Cape of Good Hope, Union of South Africa, located at longitude 19° E. and latitude 32° S. The highest peak is Sneeuwkop, 6,339 feet. They separate the valley of the Olifants River on the west from the valley of the Doorn River on the east. Cedar trees of gigantic size formerly covered these mountains, and still do so to a considerable extent. The mountains contain many Bosjesman (Bushman) caves.

CEDAR RAPIDS, city, Iowa, and seat of Linn County; altitude 733 feet; is situated on both sides of the Cedar River, connected by bridges, three of which connect with Municipal Island in mid-river. The city is served by the Chicago, Milwaukee, St. Paul and Pacific; the Chicago and North Western; the Chicago, Rock Island and Pacific; and the Illinois Central railroads. Local railways also provide interurban service. It is a railroad center situated 105 miles east-northeast of Des Moines. The city has a municipal airport for which extension and development is planned.

The city derives its name from the swiftly-flowing rapids of the Cedar River which furnishes valuable waterpower. Built on terraced hills, the city has wide, well-paved, and well-planted streets. Its cleanliness has earned for it the nickname, "The Parlor City."

Industries.—Cedar Rapids is the center for a large agricultural region, and has extensive wholesale trade. Grain (especially oats) processing is the main industry. Oatmeal, corn and sorghum syrup are major products. Poultry and stock feed, and meat and poultry packing are important. Machinery is manufactured here for road building, mining, milk processing, creamery, ice-cream, dairy-farming equipment, office equipment and bookkeeping systems, snow plows, pumps, furnaces, oil burners, and radio and broadcasting equipment. Other manufactures include electronic devices and pharmaceuticals. The Rock Island Railroad maintains repair shops here.

Educational and Cultural Facilities.—The city has a modern public school system with four high schools from which a high percentage of graduates enroll in neighboring colleges. The University of Iowa is 23 miles distant; the Iowa State College, and Cornell College are within easy distance, while Coe College, organized in 1881, under the auspices of the Presbyterian Church, is primarily a Cedar Rapids institution. The city has a public library, a memorial coliseum, and a Masonic library which contains one of the world's largest collections of Masonic books. The Art Association maintains an exhibit in its galleries in the public library, and the local talent of the Cedar Rapids Symphony Orchestra, and various music clubs and bands, provide creditable music programs. There is also a business school and Mount Mercy Junior College. Recreation facilities include baseball and football stadiums, tennis courts, and archery.

Among Cedar Rapids' native sons who attained distinction may be mentioned the late Grant Wood whose paintings have won wide recognition for him as America's "Painter of the Soil"; Carl Van Vechten, journalist and author; Bourke Hickenlooper, United States Senator; and Beardsley Ruml, notable as a promoter of pay-as-you-go income taxes. The largest element

of foreign descent in the city is Czechoslovak. A Czech newspaper is published here; and there is a Czech Fine Arts Society. The All-Iowa Fair is held annually at Hawkeye Downs.

History.—In 1841, a group of New England pioneers laid out the village and developed a sawmill wagon works, a woolen mill, and also opened a bank. After the first of the four major railroads reached it, progress was rapid. More settlers from the Middle Atlantic states arrived, and the place was operated in accordance with their sturdy traditions. In 1852, Bohemian and Czech immigrants settled in the vicinity and contributed largely to the development of Cedar Rapids. The present name was adopted when the town was incorporated in 1849. In 1856 it became a city; a commission form of government was adopted in 1908, with a nonpartisan election every two years. Pop. (1950) 72,296.

CEDAR WAXWING, the common American waxwing (*Bombycilla cedrorum*), a bird found throughout North America, breeding from the latitude of Kentucky northward. In most localities it is only partially migratory. It is a beautiful bird of delicate unobtrusive colors, generally ashy-brown with a purple tint on the head, the front of which, like the throat, is black. The tail feathers are tipped with yellow, and the secondaries have red waxy tips. The head is gracefully crested. Cedar waxwings spend most of the time in flocks, which wander according to the supply of food and are noteworthy for the uniformity with which all members alight or rise together. The food consists chiefly of berries when these are to be had, on account of which they have received the name of cherry birds in some sections. Nesting takes place late, when the summer is well advanced, and the rather bulky structure is usually placed in an apple or other orchard tree. The eggs are four to six in number, bluish gray, and thickly speckled. See also WAXWING.

CEDARBURG, sē'dër-bürg, city, Wisconsin, in Ozaukee County, is served by the Chicago, Milwaukee, St. Paul and Pacific Railroad. It is a trading center situated 17 miles north of Milwaukee. The city has various civic and fraternal clubs and six churches. Its light and water systems are municipally owned. First settled in 1842, the city was incorporated Oct. 28, 1921; its government is by a mayor and council. Pop. (1950) 2,810.

CEDARHURST, sē'dër-hûrst, village, New York, in Nassau County, is a residential community on the Rockaway peninsula on the south shore of Long Island, served by the Long Island Railroad. It is 17 miles east-southeast of New York City. The village was incorporated in 1910. Pop. (1950) 6,051.

CEDARTOWN, sē'dër-toun', city, Georgia, and seat of Polk County; altitude 809 feet; served by the Central of Georgia, and the Seaboard Air Line railroads, is situated 61 miles northwest of Atlanta. Its factories produce tire-cord fabric, cotton yarn, woolen cloth, slide fastener tape, cheese, vitamins, chemicals, disc-plows and harrows, paper products, furniture and other products. Cedar pine, poplar and oak abound in the district. Large high-grade iron

ore deposits are mined nearby, and limestone is present in great quantities. Big Spring flows eight million gallons of pure water daily to supply the city's entire needs. Cedartown is built on the site of an old Cherokee Indian meeting ground. It was incorporated Feb. 8, 1854. Pop. (1950) 9,470.

CEDILLA, sê-dîl'ă, a mark under the letter c used originally in Spanish, Portuguese and French to show that it is sibilant; to be sounded like the English s, not like k. It is written thus, ç.

CEDRELA, sêd'rê-lă, a genus of large timber trees, natives of the tropics of both hemispheres, giving name to the order Cedrelaceae, which is now usually included in Meliaceae. The species have evergreen, equally pinnate leaves, and small bell-shaped white flowers. *C. odorata* of Honduras and the West Indies yields bastard cedar. *C. australis* is a valuable Australian timber tree. *C. toona*, a native of Bengal, furnishes timber much like mahogany. The bark is very astringent, and has been found valuable in fevers, dysentery, etc. The flowers are used for producing a red dye.

CEFALU, chà-fă-lōō' (anc. CEPHALOEDUM, sêf-ă-lê'di-um), seaport city, Sicily, in Palermo Province, on the Tyrrhenian Sea, is situated 37 miles east of Palermo. It is the episcopal see of the province; its buildings include a fine Norman cathedral and several churches. Cefalu is named for the headland, 1,233 feet high, on which it originally stood, which headland bears on its summit ruins of an ancient Sicilian town. First historically mentioned in the 4th century A.C., the present town at the foot of the headland, dates from 1131 A.D., when the building of the cathedral, which has since been restored, was commenced. The harbor is small, capable of accommodating only a few vessels. Sea-fishing and marble quarrying are actively engaged in. Pop. (1936) 9,654.

CEHEGIN, thă-ě-hên', Spain, a commercial and industrial commune in the Province of Murcia, 34 miles west-northwest of the city of Murcia, four miles east of Caravaca, on a declivity facing the south. It has spacious streets, squares lined with substantial houses, and neat public buildings comprising a parish church, three chapels, town and courthouses, a prison, hospital, theater, cemetery, and several schools. Manufactures include paper, cloth, soap, pottery, brandy, wine and oil. There is also a trade in grain, oil, wine, fruits, wool, hemp, silk, wax, and cotton. Pop. (1940) commune 17,316; town 7,724.

CEILING, the interior overhead surface of a room or chamber usually formed of a lining of some kind affixed to the under side of joists supporting the floor above, or to rafters, generally to hide the floor. The term is equally applicable to a horizontal, curved, or other surface of any interior opposite the floor. It is also technically applied to certain specially prepared boarding or sheathing used in construction work. The word seems to have been suggested by the use of arched coverings for churches, and even for rooms, which prevailed in the Middle Ages, and were not unknown to the ancients. Ceilings

have been decorated by paintings since the earliest times. Egyptian temples and tombs were decorated on the undersides by blue paint, yellow stars, and other hieroglyphics of the heavens. The ceilings of Babylonia and Assyria often were gilded and stuccoed.

Greek roofings were decorated inside with ornaments. Arched ceilings among the Romans were known by the name camerae, or camera, the Greek origin of which seems to suggest that the arch was known to them. The camera was formed by semicircular beams of wood, at small distances from each other, over which was laid a coating of lath and plaster. In later times the camerae were frequently lined with plates of glass. They were then termed vitreae. Some ancient Greek ceilings were of decorated marble. The Romans had painted and relief decorated ceilings, as evidenced in their Pompeian baths. But the ceilings most common among the Romans were flat, the beams, as in modern times, having been covered with planks and plaster. Sometimes hollow spaces or panels were left between the planks, which were frequently covered with gold and ivory, or paintings. The arched ceilings of the Romans were commonly of brick or concrete covered with stucco, and were of three kinds: barrel vaults, groined vaults, and domes. Mosaic incrustation of curved roofing characterized the buildings of the Byzantine Empire. Good examples are Saint Mark's in Venice, and the churches at Salonika and Istanbul. Mohammedan art developed a similar form.

In the West, in the Middle Ages, the ceiling design took the form of bare rafters, which was later replaced by vaulting of stone and flat wooden ceilings. In England, the simpler forms prevailed; while in France the multiple rib vault and the elaborate fan vault developed. The wooden ceilings were decorated in the hammer-beam types of English churches and halls, which lasted until the 17th century. During the Renaissance, Italy used three types of ceiling, the smooth vault; the same with penetrations, having a flat central field and curves; and the flat paneled ceiling of wood or plaster, of which the most magnificent example is that in the Doge's palace at Venice, highly decorated with paintings by Titian, Tintoretto and Veronese. In England, during the early Renaissance, were developed plaster ceilings with curved lines, ornamented with heraldic devices and other patterns. At Coleshill, Berkshire, a ceiling by Inigo Jones (1650) shows a type which became predominant for a century: deeply sunk panels with medallions around and bands enriched with foliage and fruit in bold relief. The present type generally used is the one developed by Robert Adam. Modern ceilings are generally flat and are of plaster or wood. When the ceiling is divided into deep panels it is said to be coffered.

There are many examples of decorated ceilings in the United States, as in the dome of the National Academy of Sciences building in Washington, and in the Nebraska State Capitol.

CEILING, a meteorological and aeronautical term indicating: (1) Height above ground from which prominent objects on the ground can be seen and identified; also, the height above the ground of the base of a layer of clouds when over half of the sky is obscured. *Ceiling unlimited* denotes a cloudless or nearly cloudless sky, or a sky less than half obscured by clouds at levels

lower than an arbitrary fixed altitude. (2) *Absolute ceiling* denotes the maximum altitude at which a given aircraft can maintain horizontal flight under standard air conditions. (3) *Service ceiling* is the altitude, under standard air conditions, at which a given airplane is unable to climb faster than a small specified rate. (4) The maximum altitude at which an individual is able to maintain satisfactory muscular coordination and mental efficiency without artificial aids, such as oxygen or a pressurized cabin.

CEILING, a maximum sum fixed by government or other authority which may not be exceeded in the price charged or paid for any article or service, usually as of a certain date.

CELAKOVSKY, chě'lá-kôf-skě, František Ladislav, a Bohemian poet; b. Strakonice, Czechoslovakia, March 7, 1779; d. Prague, Aug. 5, 1852. He was destined for the pulpit, but chose pedagogy. In 1828 he became associate editor of the *Quarterly Review for the Catholic Clergy*, published by the Prague consistory. In 1834 he became editor of the *Bohemian Gazette*, and of the *Bee*, a literary journal. He also was a lecturer on Czech literature and language at the University of Prague. Having fallen into the disfavor of Emperor Nicholas I, he lost both positions. The Bohemian Society for the Propagation of Science elected him a member in 1840. Thereafter (1842-1849), he accepted a professorship of Slavic languages and literature established by the king of Prussia, for the benefit of his Polish subjects, at the University of Breslau. Changes in the political situation in 1848 brought him again a professorship at the University of Prague.

Of his numerous works, the following are the most remarkable: *Poems* (1822); *Slavic Folk Songs* (1822-1827); *Lithuanian National Songs* (1827); a metrical translation of Walter Scott's *Lady of the Lake* (1828); a translation of Augustine's *De Civitate Dei* (1829-1832), *Echoes of Russian National Songs* (1829); *Echoes of Czechic National Songs* (1839). One of his latest works was the *Popular Philosophy by the Slavic Nations in their Proverbs* (Prague 1851). After 1835 Celakovsky was engaged in a comparative study of all the Slavic dialects, the fruit of which is given in part in his additions to Joseph J. Jungmann's Czechic dictionary. As a poet he is distinguished by the grace and naiveté of his popular songs.

CELAKOVSKY, Ladislav, Bohemian botanist, son of the preceding; b. Prague, Nov. 29, 1834; d. there, Nov. 26, 1902. He was educated at Prague, where in 1860 he was appointed custodian of the botanical department of the Bohemian Museum. In 1882 he became professor of botany at the Czech University of Prague. His works are numerous and valuable. They include *Prodromus der Flora von Böhmen* (1867-1881); *Über die morphologische Bedeutung der Samenknospen* (1874); *Vergleichende Darstellung der Placenten in den Fruchtknoten der Phanerogamen* (1876); *Die Gymnospermen* (1890); *Das Reduktionsgesetz der Blüten* (1895).

CELANDINE, sěl'an-din (*Chelidonium*), a genus of herbs of the family Papaveraceae. The few species are natives of Europe, where

they are widely distributed, and whence they have spread to other parts of the world. One species is common in some of the older parts of the United States, having escaped from gardens. Common celandine (*C. majus*), which is most frequently seen, is an ill-smelling biennial or perennial plant with brittle hairy stems, pinnate leaves, small yellow flowers in umbels and slender two-valved pods. The plant has long been popular in old-fashioned gardens. It is easily grown from seed and produces abundant flowers all through summer. All parts contain an acrid yellow juice, for which the plant has been sometimes used in medicine, though it is now used practically only by the Eclectics.

CELANO, châ-lă'nô, Thomas of. See THOMAS OF CELANO.

CELASTRACEAE, sěl-ăs-tră'sě-ě, a family of polypetalous dicotyledons, consisting of shrubs and small trees, natives of southern Europe, Asia, America, Australia, etc., most of them of no great importance. They have generally acrid properties. The chief genera are *Celastrus* and *Euonymus*.

CELAYA, sâ-lă'yă, city, central Mexico, in the state of Guanajuato, altitude 5,750 feet, about 150 miles northwest of the city of Mexico. It has several fine plazas, handsome churches, among which is that of Our Lady of Carmen, a magnificent structure. Its manufactures are cotton and woolen cloth, candy, soap, candles, saddlery and other articles. The burning of its bull-ring, on Easter Sunday, 1888, caused considerable loss of life. Near Celaya are thermal springs. Celaya was founded in 1570, and in 1655 was raised to the dignity of a city by Philip IV. It was sacked by revolutionists in 1810. Pop. (1940) 22,766.

CELEBES, sěl'ě-běz; sěl'ě'běz, (Indonesian SULAWESI), one of the larger islands of the Malay Archipelago, east of Borneo (Kalimantan), west of the Molucca Islands, and south of the Philippine Islands, is part of the Republic of Indonesia. Its geographical situation is from latitude 1° 45' N. to 5° 37' S., and from longitude 118° 49' to 125° 5' E. Its area, including small integral islands, is 72,967 square miles. Celebes is singular in shape; it consists of four large peninsulas extending east, northeast, southeast, and south, divided by the Tomini, Tolo, and Bone gulfs. This unusual topography makes for countless harbors, inlets, and bays, and provides a shoreline of 3,500 miles, much of which is fringed by coral reefs and shoals dangerous to navigation. Though its northern part is cut by the equator, the island is wholly within the torrid zone. Celebes is considered to be remarkably healthful. Its natives often enjoy vigorous old age, and Occidentals live longer here than anywhere else in the Orient. Its extreme heats are tempered by the sea breezes, by the monthly rains, and by the north winds that prevail for part of the year. The east monsoon lasts from May to November; and the west during the remaining months.

The island is predominantly mountainous; two ridges form the four peninsulas. Several peaks are above 9,500 feet; one peak, Rantemario, reaches 11,286 feet. The absence of extensive deltas, and the incidence of broad grassy plains

between forests, distinguish the island from others of the archipelago. The scenery is varied and picturesque, and is greatly enhanced by magnificent tropical vegetation. There are a number of natural harbors, also several comparatively unimportant rivers the mouths of which are navigable by small craft and sampans. There are also numerous, and some large, lakes.

Geology.—The geological structure of the island varies considerably in the different regions. The central elevation is largely volcanic rock of the tertiary period surrounded by cretaceous rocks and alluvial deposits. Other regions are characterized by tourmaline quartzite, limestone, crystalline schist, shale, and sedimentary rock. The soil generally consists of a bed of vegetable mold, from 10 to 20 feet thick, on decomposing basalt. Gold is found in the valleys of the north peninsula which is often convulsed by earthquakes, and abounds in sulphur. Copper of good quality occurs at various points, and in Makassar, tin also, as pure as the famous Bangka tin. Nickel, iron, and lead also have been found in south Celebes. Diamonds are sometimes found almost at the surface of the ground, and precious stones are carried down in the sand of the torrents.

Natural History.—Much of the island is covered with forest, in parts almost primeval, although the valleys and plateaus are fertile and pasturable. Many kinds of palms abound, including the sago. Breadfruit trees and coconut palms are abundant. Among other kinds of trees are bamboo, oak, teak, cedar, and the poisonous upas. Plants requiring more careful cultivation are the coffee tree, indigo, cacao, sugarcane, cassava, and tobacco.

The island is almost entirely without the large carnivorous animals; neither has it elephants, rhinoceroses, or other animals of that type. Other indigenous animals are deer, wild hogs, which abound, together with the babirusa and the antelope. Crocodiles and snakes of several kinds are plentiful. Pouched animals and black tailless baboons also are found here. Trepan and turtle are caught in abundance; and mother-of-pearl fishing is carried on. Among domesticated animals are small but vigorous horses, buffaloes, goats, sheep, and pigs.

The People.—The main ethnic groups of the island are the Makassarese and the Buginese of the deuterio-Malay race; and the Tarajas and the Menadonese of the proto-Malay race. The maritime districts are largely inhabited by Malays; and in the harbors are many Chinese and others of mixed Malay and Battak origin who live in boats, roaming over the whole archipelago gaining a livelihood by fishing. The true aborigines are probably the dark-skinned jungle folk, a mild people having a distinct language of their own. The Buginese, and the Makassarese who are a well-built muscular people, originally inclined to Hinduism, are Mohammedans. They are good traders and excellent shipbuilders. Their praus, sea-worthy vessels, high-pooped in the style of the *Santa Maria*, are largely engaged in inter-island trade. The languages and literature of the people differ essentially from those of the islands and countries to the west. The Buginese and the Makassarese have an unusual written alphabet and languages of their own which belong to the Malayo-Javanese group. Being Mohammedans, their religious literature is mainly Arabic. The Mina-

hassese of the north of the island, a worthy and industrious people, have adopted the European style of living and the Christian religion which was first introduced during the 17th century. They have a native language, and also use the Malay and Dutch languages. The Gorontaloese of the northeastern peninsula, largely Mohammedan, are agriculturalists. The lingua franca of Celebes is Malay. The staple items of diet of the people generally are: rice, maize, and fish, supplemented at times, by some of them, by meat.

Principal Cities.—These are: (a) Makassar, population (1930) 84,855, a thriving modern city which is the southern trading center; (b) Menado, population (1930) 27,544, a northern port, and the oldest center of Christianity in Indonesia. The harbor of Makassar is quite modern, with good warehouses for ocean freight and copra. In the bazaars of Makassar are vendors of all the products of the neighboring islands as well as of Celebes itself. Among these are: bamboo canes, sandalwood, cajuput oil, nutmegs, rice, coffee, pearls, birds' nests, and trepan (*bêche de mer*).

Industries.—These include shipbuilding, fiber weaving, basket work and plaited articles, woodcarving, pottery, articles of gold and silver. Indigenous products of the island include fish, asphalt, timber, copra, spices, cotton, palm oil, coffee, sago, rice, corn, rattan, cordage fibers, tobacco, sugar, cocoa; gold, iron, nickel, petroleum, and coal are mined experimentally.

History.—The island of Celebes was first visited by the Portuguese in 1512. In 1607 the Dutch entered into commercial relations with Makassar and gradually acquired and extended control until, early in the 19th century, they made their supremacy complete. During World War II the island was overrun by the Japanese, and Menado and Makassar were occupied. The island was bombed by Americans, 1944-1945, and eventually surrendered to the Australians in 1945. With the proclamation of the independence of Indonesia, the name "Celebes" was officially discontinued and "Sulawesi," the Indonesian name for the island, was restored. From early 1946 until late 1949, the administration of the Republic was interrupted because the Dutch, with the support of the Australian occupation army, reoccupied the island. During the four years of their occupation the Dutch launched unsuccessful attempts to liquidate the independence movement, but with the major retirement of the Dutch in 1949, the Indonesian administration was again restored in Celebes.

Educational Activities.—The introduction of general compulsory education is one of the aims of the new Republic. Already the island has an educational system which provides primary schools for several hundred thousand pupils. There are government-maintained secondary schools, and many unregulated schools of various kinds throughout the various provinces. Special teacher-training courses are held in Makassar, and an anti-illiteracy movement is actively carried on for adults. Government-supported educational institutions on the college level will be inaugurated.

Government.—In addition to the governor, there is a provincial representative Assembly whose members are elected. The island is divided into two residences, South Sulawesi, and North Sulawesi. The government is bipartisan, and periodical elections are held. The popula-

CELERES, a body of horsemen traditionally said to have been introduced by Romulus, and to have numbered 300, consisting of citizens rich enough to furnish a horse. They are also described as subdivided into three centuries, under the names of Ramnes, Titienses and Luceres. The number of the centuries of the Celeres is said to have been raised to six by Tarquinius Priscus, this being the origin of the equites or knights, who in after times formed a separate class of citizens.

CELERIAC, sê-lêr'î-ăk, a plant, *Apium graveolens rapaceum*, of the parsley family, and a horticultural variety of celery. It is highly prized as a vegetable in Europe but is little grown in America. Unlike celery, the plant has a very thick, fleshy root. This is used in flavoring stews or it may be boiled or used in salads.

CELERY, a biennial or annual herb (*Apium graveolens*) of the family Umbelliferae. It is a native of Europe, Asia and Africa, in the older civilized parts of which it was cultivated prior to the Christian Era. In nature the plants are commonly found in moist ground, where they attain a height of from 6 to 15 inches. They have numerous leaf stalks, odd-pinnate leaves and branching leafy flower stalks two to three feet tall, bearing many small umbels of small white flowers which give place to small seeds (fruits). Cultivated celery does not differ in general characteristics from the wild plant, but by cultivation its leaf stalks (the part desired for the table) have been made more solid, less stringy and more agreeably flavored. In many instances, too, they have been lengthened or increased in number and made to form more compact plants. Celery is usually eaten raw with salt, but often it is used as a cooked vegetable, and its leaves, roots or ground seeds are frequently used for flavoring.

Commercial production of celery in the United States began in the vicinity of Kalamazoo, Mich. in the 1880's.¹ Its rapid popular acceptance led the extension of its production into some 15 important producing states. Celery production ranks about 15th in terms of acreage, 6th in terms of production, and 4th in terms of proper value among the 25 more important commercial truck crops. Marketings generally exceed 25 million crates (averaging about 65 pounds each).

Production has become highly specialized among producers, and in the major producing areas the operations have become highly mechanized. Most of the production is grown in muck soil areas in Florida and California and a few of the Great Lake states, although a considerable volume also is grown in sandy soils in New Jersey, Florida and some other states. Celery produc-

tion requires large quantities of fertilizer and humus.

Production begins with the very careful preparation of seed beds and the fields into which the plants subsequently are transferred. About four or five weeks after the seeds are sown in the seed beds, the plants are ready for transplanting into the fields, after which about 90 days are required for the plants to attain marketable size. During this growing period the crop is cultivated meticulously, sprayed with insecticides and fungicides and irrigated frequently.

The typical harvesting operation involves the cutting of the plants immediately below the surface of the ground, stripping the stalk of loose and undesirable outer branches, placing the stalks in field boxes, and cutting the tops to a stalk of uniform length. In the more important areas the celery is then hauled immediately to a packing house where the stalks are washed, sorted, and packed according to uniform sizes in shipping containers, cooled with an ice water bath the temperature of which is approximately 32°F., and loaded into refrigerator cars or trucks for shipment to market. At each stage of the production and preparation for market the work is performed by trained and carefully supervised workers. Emphasis is placed upon care, speed, and refrigeration to preserve the fresh qualities of this perishable food. Meanwhile successive plantings are proceeding a few days apart so as to maintain as even a movement of celery to market as possible.

Preferences exist in the various consuming markets for particular sizes of stalks and types of celery, depending primarily upon localized customs of housewives, restaurants and institutions with respect to methods of serving. Market price premiums and discounts vary between consuming markets, depending upon customary methods of serving and the relative supplies of appropriate varieties and sizes of stalks suitable for such customs in the local market. Consequently the marketing of celery from the shipping point becomes somewhat complex.

Prior to the early 1940's essentially all celery was blanched by "earthing up" as the celery approached marketable size, or by other means of shading the stalks with boards, paper, or straw. The blanching effect also was obtained by spacing the stalks closely in the rows so that the heavy foliage would provide the shading necessary for blanching. Later the rapid expansion and consumer acceptance of the higher-yielding Pascal type of celery permitted producers in some of the important producing areas to discontinue blanching. While consumers in some market areas were slow to accept the green Pascal type, this was largely overcome and permitted a major shift in production to the higher-yielding Pascal type. Together with improved farming practices, this contributed to a very rapid increase in average yields per acre: to from two to four times the yields obtained approximately 10 years before.

CELESTIAL MECHANICS, the branch of astronomy and applied mathematics which develops all the consequences of the law of gravitation. Its origin goes back to 1687, when Sir Isaac Newton in his *Principia* estab-

¹ Beattie, W. R., "Celery Growing," U.S. Department of Agriculture Farmers' Bulletin No. 1269, Washington, D.C., revised October, 1944.

lished the dynamical principle causing the planetary motions: "two particles of matter attract each other with a force proportional to the product of their masses and inversely proportional to the square of the distance between them." This accounted for the three facts that Johannes Kepler had laboriously deduced empirically: (1) that planetary orbits are elliptical with the Sun at one of the foci; (2) that the planets move in such a way that the radius vector describes equal areas in equal times; and (3) that the squares of the times of revolution of the planets around the Sun are proportional to the cubes of their distances from that body.

FIG. 1.—The Sun (S) in the focus of a cometary elliptic orbit.

When in the course of the 20th century it was found that the motion of binary stars conforms to the same rules, it became evident that the dynamical principle prevailing in the solar system applied as well to the most remote stars so that Newton's rules of motion rightly deserve the name of *law of universal gravitation*.

Perturbations.—If the planets' motions depended solely on the Sun's attraction, their orbits would be perfectly elliptical. But from the universality of the law of gravitation it results that the planets and their satellites also attract each other, and this produces small deviations from

on the return of the planets to similar configurations: they are the *periodic inequalities*. Marquis Pierre Simon de Laplace was the first to show that, while most of the orbital elements undergo both kinds of perturbations, the major axis of the orbit remains unchanged, if we consider only the first powers of the perturbing forces; this gives a very high approximation in the solar system where the solar mass is so dominant. He also showed that over long periods of many centuries the various elements will fluctuate between rather narrow limits: for instance, the ellipticity of any planetary orbit will never change so much that the orbit can become a parabola, nor will the inclination of the Earth's orbit on its equator continue to diminish, as it does at present, so

S●

FIG. 3.—Crosses mark the two possible locations of Trojans relatively to the Sun (S) and Jupiter (J).

far that both planes would ultimately coincide, thereby removing all seasonal effects. Laplace also found the large perturbation, caused by the mutual attraction of the two biggest planets, Jupiter and Saturn, which recurs after a little more than nine centuries.

Masses.—Since perturbations depend on the masses of the planets, they have been used inversely to determine the masses of the planets having no satellites. When a planet has a satellite, the mass is known as soon as the period of revolution of the satellite, as well as its distance from the planet, is measured. But when, as in the case of Mercury, Venus and, more recently, Pluto, there is no satellite, this direct and accurate method is not applicable. Only the per-

FIG. 4.—Tidal bulge produced in the oceans by the action of the Moon (M) on the Earth (E).

FIG. 2.—Neptune's (N) attraction perturbing the motion of Uranus (U).

purely elliptical motion, which are called *perturbations*.

There is no general rigorous solution of the mathematical problem of perturbations even in the case of three bodies. But the masses of the planets are small compared with that of the Sun, and their orbits do not differ much from circles. This makes approximate solutions possible although the analysis is extremely complicated and delicate.

Perturbations are divided into two groups. Some alter the shape and position of the orbits very slowly but continuously: they are the *secular inequalities*. Others recur at intervals depending

turbations caused by these planets on the other bodies of the solar system can give a clue as to their mass.

In the first half of the 19th century planetary perturbations were used not only for finding masses but even to predict the existence of an unknown planet. In the course of his exploration of the sky, Sir William Herschel in 1781 discovered a new planet which was subsequently called Uranus. After some years this planet showed unexplained deviations from the predicted position. Two investigators, John Couch Adams in England and Urbain Jean Joseph Leverrier in France, independently concluded in 1846 that the deviations in the motion of Uranus could be accounted for by assuming the existence of a more

distant planet, whose position in the sky could be roughly predicted. The unknown object was promptly found close to the foreseen location and was named Neptune. Its discovery constitutes one of the greatest triumphs of the theory of gravitation.

The Lunar Problem.—The problem of the Moon's motion is one of the most arduous in celestial mechanics. In this case, while the Moon gravitates mainly under the attraction of the Earth, the Sun's action enters as a perturbing force, but its amount is such that many of the approximations that could be made in the case of the smaller attractions of the planets cannot be applied here. In spite of the enormous amount of work that has been devoted to the problem, even the latest tables predicting the course of the Moon show discrepancies, which, although small, introduce errors of several seconds in the prediction of total eclipses of the Sun. The cause of the discordance is probably not to be sought in an inadequacy of the theory of gravitation. There are indications that the Earth's rotation around its axis undergoes small irregularities. A slow lengthening of the day in the course of the centuries may well account for the fact that the Moon tends to run ahead of its computed position.

The law of gravitation has given the explanation of many other peculiarities in the solar system.

Precession.—Already in the 2d century B.C. the Greek astronomer Hipparchus had noted an apparent increase in the longitude of all stars. Newton showed that this resulted from a gradual shift in the position of the Earth's axis produced by the action of the Moon and of the Sun on the equatorial bulge of the not perfectly spherical Earth. Although the Moon is so much less massive than the Sun, it is so much nearer that its influence accounts for nearly two thirds of the yearly change of 50 seconds of arc.

Tides.—The attraction of the Moon and, to a lesser extent, of the Sun on the waters of the ocean produces the phenomenon of the tides. The crest of the tide follows the Moon as the Earth rotates and appears as a periodic rising and falling of the ocean level twice a day. The height of the tide varies considerably with the changing distance of the Moon and its location far from or near to the Earth's Equator. In the course of the monthly changes in lunar configuration the Sun's influence may increase or decrease the Moon's effect. At full or new Moon the tidal force of the Sun is directly added to that of the Moon, causing high spring tides, while at first or last quarter the forces counteract each other with the result that the so-called neap tides are less than half as high as the former. In reality the crest of the tide lags behind the time when the Moon is in the meridian. This lag varies with local circumstances such as the shape of the coastline, the depth of the water, and ocean currents. For every port, the average value of this lag, called the "establishment of the port," has been determined; this makes it possible to predict the high and low tides without any particular difficulty for any point on the coast.

The Asteroid Group.—Several peculiarities in the distribution of the large number of small planets or asteroids covering the wide belt of space between the orbits of Mars and Jupiter have been accounted for by the law of gravita-

tion. The vicinity of Jupiter to these small bodies causes large perturbations in their motion and has produced in the course of time gaps in their distribution in regions where the period of revolution around the Sun is in a simple ratio to that of Jupiter.

A special case of the three-body problem, namely that of a planet making an equilateral triangle with Jupiter and the Sun in the plane of Jupiter's orbit, had been shown by Joseph Louis Lagrange in the 18th century to be a possible solution. A planet near such a location may oscillate around the theoretical position, but when the initial deviation is not too large the effect of the perturbations will be to make the body swing back and forth around the apex of the triangle, thus producing what is designated as a stable solution. A dozen asteroids moving according to this theoretically foreseen possibility have been found, some preceding and others following Jupiter, corresponding to the two equilateral-triangle solutions. They are called the Trojans because they have been given names of the heroes of the Trojan War to distinguish them from the other asteroids which are designated by feminine names.

The law of gravitation has found further application in explaining the gaps in the rings of Saturn and also the oblateness of the rotating planets.

Stellar Systems.—While, thus far, most of the features of the solar system have been accounted for by the law of gravitation, in recent years mathematical astronomers have considered the consequences of that law in the case of stellar systems. They have studied the stability of globular clusters, those large groups of stars, gravitating not around a central dominating mass, but each one moving under the influence of all the others in the group. They have studied also the still larger systems which are of the same nature as our galaxy and can be seen on photographs of the sky as spiral-like formation. A new mathematical approach was necessary to solve such problems: the individual bodies are not followed, but the probability of the behavior of any of them is considered. This leads to interesting conclusions not only in regard to the stability but also concerning the duration of these stellar systems and therefore the time scale of the universe. CELESTIAL SPHERE, an imaginary sphere (of which the apparent vault of the sky forms half) upon which all celestial bodies appear projected. Its radius must be infinitely great, so that—no matter where he may be—the observer is always at the center. For astronomical and navigational purposes, several systems of imaginary circles lie upon it, permitting the determination of the position of all celestial bodies through their spherical coordinates. See also **COLURE**.

CELESTINA, La (in full *TRAGICOMEDIA DE CALISTO Y MELIBEIA*), one of the parent sources of modern realism, was the work of Fernando de Rojas (q.v.), sometime mayor of Salamanca, whose title to the authorship of a recent Spanish scholarship has been established to the exclusion of other claimants. Originally appearing at Burgos in 1499, the 21 acts of this loose drama, or dialogued novel, provide a singularly vivid and realistic picture of the night life of a Spanish city of the Renaissance; its more unsavory features are conveyed with a touch that is absolutely modern in its directness. The story, however, of the amours of Calisto and Melibeia, as promoted by the activities of the bawd Celestina, is less happy, because of the blight of long passages of scholastic dialectic and of pseudoclassical erudition which rest heavily upon it. *La Celestina* was the point of departure of the Spanish picaresque or rogue novel, which in turn became a dominant factor in the development of the English novel.

CELESTINE I, sěl'ēs-tin; sê-lēs'tin, saint and pope: b. in Campania, Italy; d. July 26, 432; r. 422-432. He was a Roman and zealous in maintaining the faith and rights of the church and the dignity of his office. In this he was aided by Galla Placidia, mother of the boy emperor, Valentinian III. He was a close friend of St. Augustine and defended him against the Semi-Pelagians (see *CASSIANUS*). Among other heresies and schisms which vexed his reign were those of Donatism, Manichaeism, Nestorianism, Novatianism, and Pelagianism (qq.v.). Nestorius, bishop of Constantinople, whom he ordered to retract in writing or to be excommunicated, was condemned by the Third General Council at Ephesus in 431.

Celestine's last official act, perhaps the most far-reaching of his pontificate, was to send St. Patrick in 432 to preach Christianity in Ireland after the death of Palladius, whom he had sent thither as missionary-bishop in 431. Sixteen of Celestine's letters on a variety of subjects and a fragment of his discourse on Nestorianism are extant.

His feast is kept on April 6 in the Roman Catholic Church, and on April 8 in the Greek Church, where he is greatly honored for his condemnation of Nestorius.

Consult Duchesne, L., ed., *Liber Pontificalis*, vol. 1, p. 230 (Paris 1886).

CELESTINE II (GUIDO DEL CASTELLO), pope: b. Città di Castello, Umbria, Italy; d. March 8, 1144; r. 1143-1144. A pupil of Abélard, he is described as a learned priest and an upright man. As pope he lifted the interdict imposed on France by Innocent II, in his dispute with Louis VII over the bishopric of Bourges.

CELESTINE II (TEOBALDO BOCCADIPICORA), antipope: r. 1124. Elected successor to Callistus II, he resigned within a few hours to prevent a schism, after the powerful faction of the Frangipani had invaded the conclave and compelled the proclamation of its candidate, Lambert Cardinal Scannabecchi, who then ruled as Honorius II.

CELESTINE III (GIACINTO BOBONE), pope: b. about 1106; d. Rome, Italy, Jan. 8, 1198; r. 1191-1198. For 47 years he had been a cardinal deacon, when he was elected pope in

his 85th year. He was ordained priest and consecrated bishop at once. Celestine crowned Henry VI of Germany emperor and used great forbearance, whether from fear or charity, with this cruel and predatory monarch, but he excommunicated Duke Leopold of Austria, who, at Henry's instigation, had seized and imprisoned Richard I of England on that monarch's return from the Third Crusade. Celestine confirmed the new military Order of Teutonic Knights (q.v.). Against Alfonso IX of León and Philip II of France he insisted on strict interpretation of the church's laws on marriage.

CELESTINE IV (GOFREDO CASTIGLIONI), pope: b. Milan, Italy; d. Nov. 10, 1241; r. 1241. A Cistercian and the nephew of Urban III, he was elected during the papal warfare with Frederick II, but died after a pontificate of only 15 days. There was a suspicion that he had been poisoned.

CELESTINE V (PIETRO DI MURRONE), saint and pope: b. Isernia, Italy, 1215; d. Fumone, May 19, 1296; r. 1294. A Neapolitan of humble parentage, he became a Benedictine at 17 and later was ordained priest. He withdrew to the wilderness and lived as a hermit in prayer, fasting, and mortification. So many others followed his example that, before his death, there were 36 monasteries with 600 religious bearing the papal name Celestines (q.v.). Fatigued by governing his followers, he again withdrew from men and to a wilder fastness.

In a scene unparalleled in ecclesiastical history, Pietro was besieged in his mountainous retreat by a multitude of monks, led by messengers who brought news that he had been chosen pope by a conclave which, divided for 27 months, at last had united on his election. In tears he protested his elevation, but eventually obeyed what seemed to be the voice of God. In the five months of his reign Celestine made many serious mistakes, due chiefly to his inexperience in ecclesiastical polity. He scattered privileges and posts lavishly, often bestowing the same place on several suitors, and thus confused the affairs of the Curia. Incompetent, ill at ease, impatient of time taken from pious exercises for political matters, Celestine abdicated. His successor, Boniface VIII, fearing a schism, kept him a prisoner. After two abortive attempts to escape to his cave, he died in his cell in the castle of Fumone 17 months after his abdication.

Celestine's day is May 19 in the Roman calendar, where he is styled not simply St. Celestine, but St. Peter Celestine.

Consult Duchesne, Louis, ed., *Liber Pontificalis*, vol. 2, pp. 467 ff. (Paris 1892).

CELESTINES, sěl'ēs-tinz; monastic order of the Roman Catholic Church founded by Pietro di Murrone (later Pope Celestine V, q.v.), who organized it as a religious community under his personal rule. A decade later Urban IV approved it and attached it to the Benedictines (1264). First called Hermits of St. Damian, the community assumed the name of Celestines after Pietro's elevation to the papal throne. The order became moribund late in the 18th century and no longer exists.

CELESTITE, sěl'ēs-tit, a native form of strontium sulphate, SrSO_4 , crystallizing in the

orthorhombic system, and also occurring in fibrous and radiated forms. The crystals resemble those of barite, and are usually tabular or prismatic. They have a hardness of from 3 to 3.5, and a specific gravity of 3.96.

Celestite is commonly white with a vitreous lustre, but it also occurs with a pronounced bluish tinge, from which circumstance it received its name. When found in quantity it is a useful source of strontium. Fine crystals of it occur in the limestone about Lake Erie. Other important localities are in Sicily, Hungary, England, Canada, West Virginia, and California. Varieties containing large amounts of calcium or of barium are called calciocelstite and barytocelestite respectively; and the mineral itself is often called celestine.

CELIBACY, the state of being unmarried, but not implying necessarily either virginity or chastity. In Judaism marriage was a divine ordinance and sterility was a mark of divine displeasure. Celibacy, either temporary or perpetual, for certain classes in the service of temples (as the emasculated *Galli* of the cult of Attis), virginity (as the Vestal Virgins in Rome), and continence before performing certain religious ceremonies were practiced in several pagan cults. Those who embraced the ascetic way of life, as in Buddhism, abandoned their families to live as celibates. Likewise in Christianity monastic rules imposed celibacy on all members of ascetic communities. Celibacy and a vow of chastity are still required for all full-fledged members of monastic and religious orders in the Roman Catholic and in the Eastern churches. But the ecclesiastical laws concerning the secular clergy in matter of celibacy are at variance in the Christian churches of today. In the Roman Catholic Latin Church all members of the clergy in major orders, beginning with sub-deacons, are bound by a strict law of celibacy and chastity. The Eastern Orthodox churches impose the obligation of celibacy only on bishops but not on the lower clergy. This rule is followed also by the Uniates, that is, by Catholics of the eastern rites united with Rome. In the Protestant churches there are no restrictions: the same discipline regulates marriages of both ministers and laymen.

Historical Development.—There is perhaps no other ecclesiastical institution which has given rise to so many controversies about its origin, its value and its observance. As to its origin there have been three different theories: (1) that sacerdotal celibacy was a divine institution; (2) that it was established by the Apostles; (3) that it was introduced by a later ecclesiastical law. Its value has been challenged and defended in ancient and modern times according to different estimations of the disadvantages and the advantages of a celibate clergy. Its observance met for long periods the stubborn resistance of large sections of the clergy, but in modern times it has been more successfully enforced.

The theory attributing a divine origin to this law has been now discarded. There is no trace of it in the New Testament. The theory that it was instituted by the Apostles lacks historical evidence. Not all the Apostles of Jesus were celibates. Of Peter we know from the Gospel that he had a wife. It is known also that Philip had four daughters. Of the other Apostles nothing is said in the New Testament, whereupon Tertullian (end of the 2d century) remarked that

they "were either eunuchs or they lived in continence." Clement of Alexandria is witness to another tradition holding that not only Peter but also Paul and several Apostles were all married men. Paul, however, urging his followers to shun marriage gave himself as an example (I Corinthians 7:7-8). But this exhortation was addressed to all the believers in view of the imminent return of Christ to establish the kingdom. On the other hand, Paul in the same Epistle defending his claim to rank with the other Apostles stated: "Have not we the power to take with us a woman among our sisters as the other Apostles do, the brothers of the Lord and Kephas (Peter)?" Was Paul speaking of wives as it is suggested by the mention of Peter, or merely of women companions in missionary journeys? At any rate, that the Apostles made no law concerning clerical celibacy is confirmed by the Pastoral Epistles attributed to Paul in the Catholic Bible, in which it is said that a bishop "should be a man without blame and married to only one woman" (Timothy III, 2-4; Titus I, 6).

The theory now prevalent assigns to the law of sacerdotal celibacy a mere ecclesiastical origin. Very early in the church virginity and continence were exalted as having a higher spiritual value than marriage: hence it was natural that some among the more spiritually minded members of the clergy should be or live as celibates. But most of them were married men living a normal family life. Down to almost the end of the 4th century there was no *general law* imposing celibacy as a clerical obligation. Very early also, celibate members of the clergy introduced the custom of living together with a pious woman, a virgin or a widow, in a kind of spiritual marriage for purposes of mutual comfort and edification. Abuses and scandals caused by this practice led the Council of Nicaea (325) to forbid the cohabitation of clergymen with women not of their immediate family. But the same council refused to pass any law imposing celibacy on the clergy.

A canon of the so-called Apostolic Constitutions (a collection compiled about 400 A.D.) but representing an older tradition, forbade second marriages to all clerics as being bigamous unions. According to St. Jerome (c.340-420) the church in his time was filled with deacons, priests, and bishops who had married twice. The notion of bigamy was later on extended even to first marriages contracted after the ordination, since the reception of a major order was described as being a holy indissoluble marriage of the ordained man with the church. These restrictions paved the way to a more rigid ecclesiastical discipline. The main problem was that of priests and bishops who had come from the ranks of married men and after their ordination continued to live and to have marital relations with their wives. They formed the large majority of the clergy. Abstinence from such relations was already practiced in some eastern churches, especially in Egypt, where the monastic influence was very strong, but not in the western churches till the Roman synod of 386 under Pope Siricius (d. 399). In his Epistles to the Spanish and African bishops Siricius made the rule that "The priesthood of the New Testament which every day celebrates the sacred mysteries at the altar must abstain always from the works of the flesh. To all clerics in major orders all sexual relations with their wives are strictly forbidden. Those

who disobey this law shall be deposed from their office and cut off from our communion." This law did not impose the separation of married clergymen from their wives. Cohabitation was still permitted: thus, as Pope Leo I (440-461) said, "on the one hand the sacredness of marriage is respected, and on the other hand the works of the flesh cease altogether."

The Churches of the Patriarchate of Constantinople, which ignored altogether Siricius' and other western decrees, enacted their own laws at the Council in Trullo (691) imposing celibacy only upon bishops. This law still observed by the Orthodox churches greatly affected their organization because all bishoprics were now filled by celibate monks, barring the secular clergy, usually married, from any access to higher positions in the church. The Nestorian Church, on the contrary, made of marriage an obligation for all members of the clergy from the patriarch to the lesser clerics.

In the Western churches, which prospered after the conversion of the barbarians settled in the provinces of the former Roman Empire, the laws of celibacy and clerical continence were more often disregarded than observed, as we learn from the acts of many synods and papal decretals. The moral level of the clergy sank even lower with the rise of ecclesiastical feudal holdings and baronies. Bishops and priests were mostly either married or lived openly in concubinage. The Gregorian Reform of the 11th century reestablished a measure of discipline by strictly enforcing the law of celibacy, but the evil of concubinage could not be suppressed altogether. There was even a recrudescence of it during the period of the Renaissance when high prelates and even some popes gave the bad example of having irregular families. It must be said, however, that throughout those centuries there were always in the church shining examples of clerical virtue and of strict observance of the laws of celibacy and chastity. The ideal of sacerdotal purity and renunciation was always kept alive.

After the Protestant Reformation which cast away the whole Canon Law, the Catholic Church by the disciplinary reform of the Council of Trent (1545-1563) was able to enforce more strictly the law of clerical celibacy and continence. This law being merely an ecclesiastical ordinance could be modified or abolished altogether by the supreme legislative authority of the church, the pope. As a matter of fact, Pope Pius VII (1800-1823) yielding to the request by Napoleon granted a dispensation from the vow of celibacy and chastity to hundreds of French priests who during the revolution had contracted civil marriages. Those priests, however, were reduced to the state of laymen unable to perform any religious ceremony or to fill any ecclesiastical office.

Bibliography.—A minute bibliographical survey of all texts and writings on this subject from early Christianity to 1860 was published in 1861 by A. de Roskovany (a volume in 8vo of 708 pages). A second volume brought the survey down to 1888. In the 19th century hundreds of writers, mostly Germans, dealt with this subject. The most complete work in English, though marred by inaccuracies, is still C. Lea's *An Historical Sketch of Sacerdotal Celibacy in the Christian Church*, 2d ed. (1884). See also Vacandard, E., "Les origines du célibat ecclésiastique," in *Études de critique et d'histoire religieuse* (1905); Leclercq, Dom H., "La législation conciliaire relative au célibat ecclésiastique," in the French edition of Hefele's *Histoire des Conciles*, vol. 2, pp. 1321 ff.; Thourston, H., "Clerical Celibacy in the Anglo-Saxon Church," in *The Month* (1909). For the evidence supplied by epigraphic material see Dom H. Leclercq, article, "Célibat" in Dic-

tionnaire d'Archeologie Chrétienne et de Liturgie, vol. 2 pp. 2808 ff. (1925).

GEORGE LA PIANA.

CELINA, village, Ohio, Mercer County seat altitude 875 feet, on the Cleveland, Cincinnati Chicago and St. Louis, and the New York, Chicago and St. Louis railroads. It makes furniture and has creameries and canneries. There are two hospitals and a public library. Celina was settled in 1834. It has mayor, council, and city manager. The water, power and light system are municipally owned. Pop. (1950) 5,703.

CELL, *The*. A microscopical unit of structure of living organisms. Large organisms have many cells, smaller organisms have fewer, sometimes only one. All cells have certain structural features in common regardless of the organism or tissue in which they are located, and under appropriate conditions they carry on the vital functions of respiration, metabolism, growth irritability, movement, reproduction, and so forth. They may live and reproduce after isolation from the parent body (tissue culture) and can be regarded as individuals of a lower order. All cells arise from pre-existing cells by cell division (doctrine of cell continuity). Since all vital activities are carried on by individual cells working either singly or in coordinated groups it is evident that all of the problems of normal or disordered function have their basis in cell physiology.

Methods.—The parts of a living cell are often nearly or quite invisible under the ordinary microscope, either because their refractive powers are so similar, or because their size lies below the limit of resolution of the lenses used. Techniques of killing, sectioning, and staining cells (classical methods) have long been used to make cell parts visible. These techniques have been particularly successful in studies of the chromosomes but less so when applied to smaller, highly hydrated structures.

New methods were developed to supplement the classical ones, some of which are listed here: (1) polarization microscopy—adapted to detect areas of molecular orientation; (2) ultraviolet microscopy—which improves resolution and gives differential absorption; (3) electron microscopy—which gives much higher resolution but is limited to thin, dead objects; (4) phase microscopy—which reinforces slight differences of refractive power; (5) microdissection—which utilizes apparatus for the dissection and injection of single cells; (6) centrifugation—which results in the stratification of the cell constituents and makes it possible to determine their relative densities; (7) microrespirometry—which permits the measurement of cellular respiration; (8) tissue culture—facilitating experimental treatment of living cells isolated from multicellular organisms; (9) biochemical and biophysical methods which have made possible the isolation and analysis of nuclei, of chromosomes, of chondriosomes and of several specifically different granules. These researches form the basis as triumphs of modern biological research.

Cell Structure.—A cell consists of a plasma membrane enclosing a mass of cytoplasm and a nucleus, (Fig. 1A, B, and C). Structures external to the plasma membrane such as hyaline membranes, the cellulose wall of plants, and the hard matrix of bone are cell products. The

plasma membrane plays a dominant role in determining what enters and leaves the cell, and the electrical charge upon it is related to the degree of excitation of the cell. It is believed that the plasma membrane may be only a few molecules thick and that it consists of highly oriented layers of protein and lipid.

FIG. 1.—Diagrams of various types of cells. *A*, non-dividing cell showing structure: *a*, plasma membrane; *b*, cytoplasm; *c*, chondriosomes; *d*, stored material; *e*, nuclear membrane; *f*, nucleolus; *g*, chromatin; *h*, central body with paired centrioles; *i*, golgi material. *B*, centrifuged cell showing stratification of its contents in accordance with their specific gravities: *k*, oil at the centripetal pole; *l*, golgi material; *m*, clear cytoplasm; *n*, nucleus; *o*, chromatin; *p*, nucleolus; *q*, mitochondria; *r*, yolk. *C*, plant cell with *s*, large vacuole; *t*, cellulose wall; *u*, nucleus; *v*, cytoplasm; *w*, chloroplast. *D*, human sperm cell (spermatozoon) total length 0.60 mm. The nucleus is confined to the head: *a*, head; *b*, neck, containing centriole; *c*, middle piece, containing mitochondria; *d*, main piece, *e*, tail piece. *E*, motor nerve cell showing: *a*, dendrites; *b*, cell body, containing niessl granules; *c*, nucleus. The nucleus contains a nucleolus; *d*, myelin sheath; *e*, axone filament. *F*, cell from the embryonic region of a growing pea root tip: *a*, cell wall; *b*, cytoplasm, containing fine granular mitochondria and larger (*c*) amyloplasts. Amyloplasts may bear a round starch granule at one end; *d*, nucleus with chromatin and a nucleolus. *G*, unicellular animal, amoeba, showing: *a*, plasma membrane; *b*, food vacuole; *c*, nucleus; *d*, contractile vacuole; *e*, inner granular cytoplasm (endoplasm).

Cytoplasm.—The cytoplasm comprises all of the cell substance inside of the plasma membrane and outside of the nucleus. It consists of the structures diagrammed in (Fig. 1*A, B, C*) and listed below: (1) an apparently homogeneous ground substance, (2) visible and submicroscopic granules, (3) plastids, (4) golgi apparatus, (5) chondriosomes, (6) fibrils, (7) vacuoles, (8) stored products and crystals, (9) centrosomes, and, at the time of division, (10) the achromatic figure. The ground substance is an aqueous solution of soluble proteins, metabolites and salts, having the properties of a thixotropic gel. Some of the larger granules represent presecretion products (digestive enzymes, etc.). Some of the submicroscopic granules have been isolated in a relatively pure state and contain protein, nucleoprotein and intracellular enzymes. Stored products include starch in plants, glycogen, and fats and oils in animals. Sometimes crystals are stored in large numbers.

Plastids occur exclusively in plant cells. They include: (1) leucoplasts which are small and numerous in young cells; (2) chromoplasts which contain colored pigments. The most common being the chloroplast which contain

chlorophyll and is concerned with the formation of starch by photosynthesis and (3) amyloplasts which occur in roots and stems and are also concerned with starch formation. Plastids reproduce by division though not necessarily at the time of cell division. Their possible origin *de novo* is debated. It is believed that chromoplasts and amyloplasts are formed from leucoplasts. Plastids are generally inherited from the maternal parent.

In 1909, Camillo Golgi described the Golgi apparatus as a constant feature of certain nerve cells. A basic criterion for its presence was stainability with osmium tetroxide or silver nitrate associated with a high lipid content but many structures in different cells will stain with these reagents. Some workers question the validity of osmic or silver staining and prefer vital stains which demonstrate an "apparatus" of vacuoles. After many years of controversy authorities are still in wide disagreement regarding what is admissible as golgi. A group of osmium staining bodies, found in animal spermatocytes, fuse and produce the acrosome (penetrating tip) of the sperm. Osmium staining bodies are frequently associated with secretion granules or stored products suggesting synthetic activity. The "golgi apparatus" can be displaced as a unit in some centrifuged cells (Fig. 1*B*) so that it is impossible to doubt its reality in individual cases. The homologies and analogies of "golgi material" in different cells remain very uncertain.

The chondriosomes are of widespread occurrence in plant and animal cells. They may be filaments or granules (mitochondria) which move about rapidly in the cell (tissue culture), divide by fission and stain with Janus green or red. They have a relatively high specific gravity among cytoplasmic components for they are thrown centrifugally when centrifuged. Isolated chondriosomes from mammalian liver cells contain protein, nucleoprotein, lipid and enzymes among other substances. Critical evidence of their function is lacking although they are often associated with secretion products.

In many animal cells there is a central body which is passive except at the time of division. Sometimes a dotlike centriole (or a pair of them) lies in the center of the central body. During cell division the central bodies are at the poles of the gelated spindle which occupies the center of the cell and to which the chromosomes are attached. The central bodies represent the focal points of the astral rays. They perpetuate themselves by division but are also formed *de novo* under certain circumstances. They are included in the sperm and in many cases are introduced into the eggs at fertilization.

Nucleus.—The nucleus is surrounded by a membrane which encloses nucleoplasm, one or more nucleoli and chromosomes. It is often spherical but may be oval, irregular, and even fragmented. Its presence is essential to the continued life of the cell. An amoeba, for example, deprived of its nucleus may live for some days but will ultimately perish.

The chromosomes are the carriers of the genes. Their appearance differs markedly in different stages of nuclear development but they are most easily seen at the time of cell division. Structurally, they are threads which are contracted and coiled during division stages but are

much extended in nondividing cells. They (1) consist largely of nucleoprotein (2) exist as pairs, one member of maternal and one of paternal origin, which are, however, only closely associated during the first division of meiosis; (3) are generally of a constant number in all body nuclei; the number is a constant one for each species; (4) their pairing behavior and distribution during gamete formation in animals and spore formation in plants are consistent with Mendel's laws of segregation and independent assortment and with Morgan's laws of linkage and crossing over; (5) the chromosome number is perpetuated by a precise longitudinal division of each chromosome during mitosis. The science of cytogenetics has shown that each chromosome is differentiated along its length into regions (genes) responsible for the hereditary traits and by special techniques it has shown the position of particular genes on the chromosome. One or more chromosomes is often recognizable as a sex chromosome. Commonly a like pair occurs in one sex and an unlike pair in the other. In many animals and in some plants the sex is primarily determined by the distribution of the sex chromosomes, although the other chromosomes and sex hormones also exert their effects.

Size and Shape.—The size and shape of a cell are closely related to the functions it must perform (Fig. 1*D, E, F*). Red blood cells are small and smooth, favoring their passage through small capillaries. Many nerve cells bear a long cellular process over which the impulse is transmitted. Egg cells are relatively large containing much reserve nutrient for the prospective embryo. The human egg (diameter 0.135 millimeters) has about 7,000 times the volume of the human red blood cell. There is evidence that the size of a cell and the size of its nucleus are dependent characteristics (nucleo-plasmic ratio).

Exceptions.—There are certain exceptions to the generalized cell pattern; for example, voluntary muscle fibers of vertebrates and the hyphal threads of molds have many nuclei in a common mass of cytoplasm. Such exceptions are, however, fully consistent with the cell doctrine since their many nuclei arise from a uninucleate cell. Whether or not bacteria are cellular is undecided. A favored interpretation considers them to be plurinuclear cells. Colon bacilli, for example, have several condensed bodies which stain as desoxyribose nucleic acid as does chromatin, and can be considered as nuclei. How closely the stainable material of the chromosomes, the viruses and phages resemble cells remains for future work to determine.

Cell Division.—In mature organisms, cell division, is limited to cell replacement which proceeds constantly, for example, in the lower layers of the skin or in the blood forming cells of the bone marrow.

When a cell divides, its nucleus divides first, then its cytoplasm. Nuclear division is essentially similar in all forms with true nuclei, differing only in details. The process, diagramed in Fig. 2, called mitosis, can be summarized in the following steps: (1) The chromosomes of the nondividing cell are long, nonstainable and hydrated. Only scattered granules of chromatin are visible (Fig. 1*A*). (2) As the first phase of mitosis approaches (prophase) the chromosomes become shortened, stainable and dehydrated (Fig. 2*A, 2B*). (3) The nuclear membrane disappears

Fig. 2.—Diagrams of phases of mitotic cell division. *A*, early prophase—chromosomes condensing. *B*, late prophase—chromosomes further condensed, spindle and asters appearing. *C*, metaphase—spindle and asters well developed, chromosomes split ready for the separation of halves, chromosomes oriented at the spindle equator. *D*, Anaphase—chromosomes halves separating, spindle elongating. *E, F*, Telophase—chromosomes swelling and vacuolating, centrioles each divided, cell dividing. *G*, one chromosome with attached spindle fibers, showing the longitudinal split of the chromosome (metaphase). *H*, early stage of the separation of the chromosome halves (early anaphase). *I*, daughter chromosomes separated (anaphase).

and a gelated spindle appears, (late prophase). (4) The chromosomes become attached to the spindle by their kinetochores (spindle attachment bodies) and become arranged at its mid-plane (metaphase, Fig. 2*C*). (5) The half chromosomes separate, kinetochores first, and move towards opposite poles (anaphase, Fig. 2*D*). (6) The chromosomes swell, vacuolate (Fig. 2*D*) to form two new nuclei (telophase, Fig. 2*E* and *F*). Cytoplasmic division follows either by a constriction of the cell (animal cells) or by the formation of a cell plate across the equator of the spindle which is subsequently transformed into cellulose (plants). The essential feature of mitosis is the precise splitting of each chromosome in half, thus insuring each daughter cell an identical chromosome (and genic) complement.

Cell Differentiation.—During the development of an organism its constituent cells become specialized both in structure and in function. The cause of cell specialization is one of the outstanding biological problems. Progress has been made (a) by modifying the environment of a group of undifferentiated cells and thus altering their eventual fate, (b) in tissue culture by modifying the culture fluid, and (c) in embryos by transplanting and relocating patches of embryonic cells.

History.—Robert Hooke (1665) first used the term cell (cellula) in describing dead cell areas of cork. Robert Brown (1831) described the nucleus as a constant feature in plant cells. Matthias J. Schleiden (1838) and especially Theodor Schwann (1839) established the cell theory, recognizing the cell as a unit of structure in both plants and animals. They realized the common structure of cells in different tissues although they held erroneous views concerning cell origin. The doctrine of cell continuity was first clearly stated by Rudolf Virchow (1858) and the first careful studies of mitosis were made by Edward Strasburger and by Walter Flemming in 1875. The chromosome theory of inheritance was developed by Walter Sutton in 1904. Ross G. Harrison originated the tissue

culture technique in 1907.

ALLAN C. SCOTT,
Union College, Schenectady, New York.

CELL, a small chamber; the dwelling of a hermit; a lesser or subordinate religious house dependent upon a greater, by which it was erected and under whose government it remained; the apartments or private dormitories of monks and nuns. In early Christian usage the word was also applied to a chapel erected over a tomb.

CELLE, tsël'ë, city, Germany, in the state of Lower Saxony, on the Aller River, 22 miles northeast of Hannover. It is a rail junction and the site of important oil, steel, and chemical industries. The city was chartered about 1292. Pop. (1950) 60,100.

CELLINI, chë-lë'në, **Benvenuto**, Italian goldsmith and sculptor: b. Florence, Italy, Nov. 3, 1500; d. there Feb. 13, 1571. Though he is now best known for his autobiography, which was not published until long after his death, Cellini achieved considerable fame during his lifetime as goldsmith and sculptor. His father wished him to become a musician, but he apprenticed himself to a goldsmith at the age of 15 and remained in this profession until the end of his life, devoting an increasing amount of time in his later years to sculpture. At 19, without even telling his father, he departed for Rome; as he says in the autobiography, "I had just 19 years then, and so had the century." From 1519 to 1540 he remained chiefly in Rome, returning to Florence several times (1521, 1527, 1528, 1535). On the last of these trips he remained for a while in the service of Duke Alessandro de' Medici. In 1537 he made a short trip to France. His headstrong, violent temperament, which led him constantly into trouble and more than once to murder, was responsible for several of these abrupt moves.

His early works in Rome show the influence of Raphael and his pupils and of the Milanese goldsmith and medalist Cristoforo Foppa Caradosso, as may be seen in a medal made about 1521 or 1522 for Scaramuccia Trivulzio, a seal made for Ercole Gonzaga in 1528, and the famous gold morse made for Pope Clement VII in 1530 and 1531. The morse, like most of Cellini's works in precious metal, is no longer extant, but its design has been preserved in careful water-color drawings made in the 18th century by Francesco Bartoli. Later, particularly after the trip to Florence in 1535, Michelangelo's influence is stronger. This may be seen in the medals made for Pope Clement VII in 1534, in that of King Francis I of France about 1537, and in the seal made for Ippolito d'Este in 1539.

His admiration for Michelangelo, which he expresses so often in the autobiography, shows most strongly in the famous gold saltcellar of Francis I, now in the Kunsthistorisches Museum in Vienna. Designed in Rome early in 1540, it was finished in France, where Cellini went later that year, remaining in the service of King Francis until 1545. Several of the figures decorating the saltcellar are copied directly from the statues symbolizing the times of day which Michelangelo made for the Medici tombs in

Florence between 1520 and 1534. Indeed the whole style of the sculptured figures on the saltcellar is an ornamental adaptation of Michelangelo's style. Impressive in scale (over 10 inches high and 13 inches wide), the elaborate table ornament features large nude figures of the sea god Neptune and a female figure symbolizing the earth. Handsomely shaped, these figures are in precariously balanced poses, achieving that combination of elegance and tension so popular in the mannerist style prevailing at this time. On the sea side are a richly shaped ship to hold the salt; sea horses and many kinds of fish, all worked in gold and enamel. On the land side the pepper container is in the form of an Ionic building ornamented with statuettes, and there are also many small land animals. On the pedestal are relief figures symbolizing the times of day and the winds. The constant change in scale in the human figures is a further element of tension, as are the closely intertwined forms and the actively fretted surfaces of the work.

All this is typical of mannerist art, of that anticlassical, anti-Renaissance style which gathered increasing momentum in the second and third quarters of the 16th century after the great climax of the Renaissance in the first decade of that century. Arising in and expressive of a time of crisis both in religion and in state affairs, mannerism matured in an atmosphere of increasing autocracy. In Cellini's work we see relatively little of the religious intensity found in Jacopo da Pontormo or in the late works of Michelangelo that Cellini so admired. We see, however, both in works such as the saltcellar of King Francis and in the many stories in the autobiography something of how princely patronage affected the growth of mannerism into an increasingly sophisticated and cerebral style.

As one can sense in the saltcellar of Francis, Cellini long had wanted to devote more of his time to sculpture, and the wise and liberal patronage of King Francis made this possible for him for the first time. Francis was delighted with Cellini's work and rewarded him bountifully, even presenting him with a castle for use as a home and workshop. Of the large-scale works he made in France only the bronze *Nymph of Fontainebleau* has been preserved. Made in 1543 and 1544 as part of an ornamental framing of a portal for the Palace of Fontainebleau, it was never installed there and is now in Paris in the Louvre. The mannerist taste for tense expression shows in the abrupt contrast in style between the rugged realism of the dogs, boars, and deer at the sides of the composition and the elegant, elongated nude form of the nymph.

In one of those sudden changes of heart which punctuated his life, Cellini began to worry about his sister and nieces at home and abruptly left his hard-won position in France and returned to Florence in 1545. Here he entered the service of Duke Cosimo I de' Medici and remained in Florence for the rest of his life. One of his first commissions on his return was the restoration of an antique marble torso, to which he added a head, arms, feet, and an eagle, transforming it into a Ganymede (now in the Bargello in Florence). The elongated mannerist proportions of Cellini's additions clash with the more heavily proportioned classical torso, showing how deeply ingrained a taste can become.

Renewed contact with classical works and with those of the great Renaissance masters,

Donatello and Michelangelo, seems to have revitalized Cellini's sculptural sense; his works in Florence show a marked improvement in quality over the *Nymph of Fontainebleau*. The most important of these works is the famous bronze Perseus, which still stands in the spot in the Loggia dei Lanzi for which it was made on the order of Duke Cosimo. This work occupied Cellini from 1545 until 1554. The dramatic story of his difficulties in casting it forms one of the most fascinating sections of his autobiography. Though the figure of Perseus is more heavily and more classically proportioned than most of Cellini's works, the flavor of the whole work remains mannerist in many important ways: in the strained, awkward relation of the helmet to the head; in the studied contrast of the handsome nude youth with the horrifying severed head of Medusa gushing blood; in the obvious relish taken by the artist in the gory aspects of the story. Again he accents marked changes in scale from the main group to the four small bronzes of gods in the niches of the pedestal and still further in the delicate elongated form of Andromeda in the relief below representing Perseus rescuing Andromeda (the original of which is now in the Bargello). The small bronzes in the pedestal niches are particularly beautiful and more typically mannerist in proportion and pose than the main figure of Perseus.

Two marbles also of mythological subjects, Apollo and Hyacinth (1546) and Narcissus (1547-1548) were long thought to be lost, but have been identified in the Bargello collections. Of Cellini's large scale portrait busts there remain the bronze in heroic scale of Cosimo I (1545-1548) in the Bargello and that of Bindo Aldoviti (1550) now in the Gardner Museum in Boston, Mass. His last important work in sculpture was the life-size marble crucifix now in the Escorial, Spain, which he made for his own tomb between 1556 and 1562. Poised and cool on first impression, this figure conveys intensity of feeling through subtleties of tense modeling and facial characterization.

In one of his many spurts of religious zeal, Cellini took preliminary vows in 1558, but sought and obtained release from them in 1560. About 1564 he married Piera di Salvatore Parigi. It was during these years (between 1558 and 1562) that he wrote his autobiography. Although the autobiography was not published until long after his death, the treatises which he wrote on goldsmithery and on sculpture between 1565 and 1567 were published in 1568 with a dedication to Bernardo Cardinal de' Medici.

Consult *The Life of Benvenuto Cellini, Written by Himself*, ed. by John Pope-Hennessy (London 1949). This edition contains the John Addington Symonds' translation, further notes, a critical introduction, notes on most of Cellini's extant works, and bibliographical references.

CELLINI'S AUTOBIOGRAPHY. Written between 1558 and 1562, the autobiography was not published until 1728, when the first Italian edition appeared. It was translated into English (1771), German (1796), and French (1822), becoming more and more popular in northern Europe with the growth of the Romantic movement, even becoming the inspiration for an opera, *Benvenuto Cellini*, by Hector Berlioz. Johann Wolfgang von Goethe was moved to translate it, and lavish praise has been heaped on it ever since the late 18th century. Horace Walpole declared it

"more amusing than any novel"; Stendhal, who knew and loved Italy well, found it the key to an understanding of "Italian character." Cellini's tale of intrigue, brawls, duels, and escapes is so violent and extravagant that often one hesitates to believe him, but he usually is corroborated by the accounts of other witnesses. And this facet of his story alternates constantly with other moods, giving us glimpses of his devotion to his art, his tireless energy, his moments of intense piety, his casual pleasures, his humor, his essential warmth of heart. In an age of proud individualists Cellini's vanity was not only normal, but almost a necessary weapon in the struggle for position and advancement. He begins by even attributing the naming of the city of Florence to a legendary ancestor, Fiorino of Cellino. Later he tells us almost casually of "the special gift which the God of nature bestowed on me, that is to say, a temperament so happy and of such excellent parts that I was freely able to accomplish whatever it pleased me to take in hand." However, he later criticizes the sculptor Jacopo Sansovino for boasting. And he is equally frank about his weaknesses. Some of the freshness and liveliness of the autobiography come from the fact that most of it was dictated; the original Italian is colloquial and racy. John Addington Symonds' translation (1887), though the best in English, errs in seeking to achieve a literary elegance not in keeping with the original text. Through Cellini's words we are given not only an unusually candid picture of himself but also of his time. As Goethe said: "I see the whole century in more real terms in the confused apprehension of an individual than in the clearest historical account."

CELLITES, sɛl'its, or **ALEXIAN BROTHERS**, a religious order, so called from their patron St. Alexius and from *cella*, tomb, from the fact that they originally cared for and buried plague victims. The brotherhood arose in Mechlin, Brabant, about 1300 to check the ravages of the black death and soon spread through Brabant, Flanders, and Germany. At first the Cellites were merely a pious society, intended to harbor the poor and indigent free of charge, to serve the sick, and to bury the dead. In 1469 they were organized as a religious order.

CELLOPHANE, sɛl'ō-fān, viscose solidified in thin, transparent, waterproof sheets, invented by Jacques Edwin Brandenberger, a French chemist of Thaan. Pursuing further studies of viscose, which had been manufactured in England since 1894, he discovered in 1908 a process for making brittle, sparkling, transparent sheets of regenerated cellulose, which he believed could be utilized commercially as wrappings for gift packages. Obtaining patents in Europe and the United States, he designed machines for its manufacture, perfected in 1912. As a trade mark he coined the word "cellophane," derived from the first syllable of "cellulose" and the last syllable of the Greek word *diaphane*, meaning transparent. During World War I the French government purchased his entire output to use as eyepieces for gas masks. When the war ended, Brandenberger had developed cellophane cellulose film into a stable product. A French company, the Comptoir de Textiles Artificiels, placed capital at his disposal, and a company called La Cellophane was organized in 1920. In 1923 a subsidiary of E. I.

Pont de Nemours and Company obtained from Comptoir the North American manufacturing rights, and the following year the first sheet of cellophane was produced commercially in the United States.

CELLULOSE, sĕl'ŭ-lās, an enzyme which acts in the digestion of cellulose, a carbohydrate which, in various forms, is universally found in plants. The result of this digestion is cellobiose, which, acted on by at least one other enzyme, is transformed into glucose. Thus there are two enzymes and probably more which effect the digestion of cellulose to glucose. These enzymes are present in certain microorganisms, notably fungi, which attack such substances as cotton fibers, flax, hemp during retting, cordage, paper.

CELLULOID, sĕl'ŭ-loid, an artificial substance invented in its modern form by the brothers Hyatt (Isaiah and John Wesley), of New Britain, N. J., in 1869 (patent issued 1870). It is commonly used as a substitute for ivory, bone, shell, rubber, and coral, and has a close resemblance to these substances in hardness, elasticity, and finish. It is composed of the lower nitrates of cellulose gelatinized in a solution of camphor in methyl or ethyl alcohol. The nitrates of cellulose are usually prepared by subjecting tissue paper to the action of a bath of mixed nitric and sulfuric acids for 20 minutes at a temperature of at least 30°C. The resulting substance is dried by blotting or by the use of alcohol, and incorporated by heat or mixture with alcohol, camphor, and any pigments or fillers that may be desired. The doughlike mass then resulting is pressed into forms by various means, and these forms are then being kept from one to six weeks at 60°C. to evaporate the alcohol. Celluloid is stable at 75°C. It is very inflammable and its low tensile strength makes it one of the strongest of artificial materials. It is used for films in cameras and moving pictures, but on account of its excessive inflammability is being replaced by preparations of cellulose treated with acetyl chloride. Celluloid varnishes for lacquering on metal are prepared from various pyroxylin preparations and pigments.

CELLULOSE, sĕl'ŭ-lōs. The cell walls of higher plants are made chiefly of cellulose, which is a carbohydrate having a composition corresponding to the formula $(C_6H_{10}O_5)_n$. It is very widely distributed in the vegetable kingdom and occurs in one form or another in practically every country in the world. The cellulose content of different plants varies considerably: cotton fibers contain in excess of 90 per cent cellulose, whereas saw wood contains but 30 per cent cellulose. Cellulose is found in wood; in cotton, kapok, and other seed fibers; in flax, jute, ramie, hemp, and other bast fibers; in straw, bagasse, rice hulls, and in a large number of other plants.

Cellulose cannot be used as a food by man or other carnivorous animals, since they lack the enzymes needed for hydrolysis. However, a small amount of cellulose is properly included in foods, as it gives bulk to the intestinal contents and aids in the movement of food through the intestinal tract.

Historical.—The use of cellulose for making paper apparently had its origin at the beginning of the 2d century A.D. in China, spreading from

there to Arabia and then to several European countries. In the 15th century, paper made from vegetable fibers became an important product. Friedrich Gottlob Keller invented a mechanical process of making wood pulp in 1841 and the soda process was developed between 1851 and 1854 by the Englishmen Charles Watt and Hugh Burgess. The first sulphite process patents appeared in 1866; the sulphate or kraft process was developed in 1879 and was introduced in the United States in 1908.

The first known cellulose derivative, gun-cotton, or fully nitrated cellulose, was patented in 1846 by Christian Friedrich Schönbein. This was followed by a patent in 1855 for the manufacture of artificial threads from nitrated cellulose. Cellulose nitrate was the first synthetic plastic of industrial significance, being used as an ivory substitute in 1868 by John Wesley Hyatt. In 1890 the cuprammonium process for the manufacture of rayon appeared and in 1892 the viscose rayon process was introduced. In 1894 the first patent appeared for the production of cellulose acetate filament and in 1906 was made an acetone-soluble acetate which later was used as a non-inflammable lacquer for airplane wing coatings. Cellulose acetate plastics have won industrial importance since the early 1930's. Cellulose ethers were introduced in Europe in 1912 and the Dow Chemical Company developed methyl cellulose in 1939.

The conversion of cellulose in wood to fermentable sugars has received much attention, being first attempted on an industrial scale in 1910 and leading to the development of two industrial processes: the Bergins process which is based on using a 40 per cent hydrochloric acid; and the Scholler process which employs a dilute sulphuric acid solution.

Chemical Nature.—The molecular weight of the building unit of cellulose is 162 and it can be considered a trihydric alcohol containing some 2,000 to 3,000 beta glucoside units. Structurally, a portion of the cellulose molecule may be represented as follows:

The above formula for cellulose derived from chemical evidence has been confirmed by X-ray examination. Furthermore, it has been shown that many of the molecules in the fibers are arranged with crystalline regularity and that the crystalline portions are separated by amorphous regions having an irregular molecular structure. The proportion of amorphous to crystalline structure affects the physical properties of the fibers, such as strength and flexibility.

Cellulose is insoluble in water, alcohol, ether, chloroform, and other organic solvents. It is soluble in Schweitzer's reagent which is prepared by agitating copper powder or copper hydroxide with concentrated ammonium hydroxide. Cellulose is also soluble in a mixture of one part of zinc chloride and two parts of hydrochloric acid.

Hydrolytic degradation of cellulose to varying degrees may be accomplished as follows:

It is possible to obtain a 95 per cent yield of glucose on complete hydrolysis of the purified cellulose.

Various means are available to effect the degradation of cellulose, resulting in a reduced molecular weight. In some phases of commercial practice this is performed to reduce viscosity, thus improving the ease of handling. Degradation can be performed with acid, alkali, and oxidizing agents resulting in end products such as hydrocellulose and oxycellulose.

Heat results in the destructive distillation of cellulose to end products such as ethylene, carbon monoxide, methyl alcohol, water, acetone, acetic acid, carbon dioxide and methane. Less drastic treatment results in a decrease of tear and bursting strength and viscosity while the copper number and acidity are increased. At 200°C. the fiber structure is lost and at 250°C. the material becomes practically amorphous.

Chemically, cellulose has been separated into several classifications and various analytical methods have been developed for their determination. The classifications include: alpha, beta, and gamma cellulose, alkali-soluble cellulose, chlorine demand, ether extract, ash, iron, manganese, calcium, and silica. Alpha cellulose is insoluble in cold 17.5 per cent sodium hydroxide; beta cellulose is soluble in 17.5 per cent sodium hydroxide and is precipitated on acidification with acetic acid; gamma cellulose is that portion that remains in solution after precipitation of the beta cellulose. The above specifications, including viscosity, are generally the basis upon which chemical cellulose is purchased.

SOURCES

Seed Hairs.—The matured cotton fiber is a flattened and twisted single hairlike cell. The cotton seeds are surrounded by the soft white fibers which have been used by man for years and of which there are two kinds. The long fibers are called lint and the short ones, fuzz. The lint length varies with different species averaging about one inch for the cotton produced in the southern United States.

The hairs are removed from the seed by a process known as ginning. The lint and fuzz still remain, however, and these are removed from the seed by a "linters" machine.

The cotton linters are sorted into various grades having different fiber lengths and known as first cut, second cut, mill run and hull fiber. First cut are used for surgical dressings, low-grade yarns and padding materials. Second cut and hull fiber are employed in the manufacture of chemical cotton.

A typical analysis of American raw cotton is given below:

Cellulose	91	per cent
Wax, etc.	0.35	per cent
Pectic Matter	0.53	per cent
Mineral Matter	0.12	per cent
Water	8	per cent

Cotton is the preferred material for the manu-

facture of cloth. It is readily purified and large quantities are used in the chemical field for products such as plastics, explosives, lacquers, and synthetic fibers.

Bast Fibers.—These fibers are present in the form of long bundles in the inner bark of various plants. Considerable use is found for these in the textile field. The bast fibers of the flax plant yield linen. The plant consists of 8 per cent of fiber.

The flax is prepared by a process known as retting which consists of a breakdown and partial cell separation by the action of bacterial enzymes. Its principal use is in the manufacture of thread and fine cloth.

The preparation of hemp fiber is similar to that of linen. The hemp fibers are less pliable than flax, however, and are coarse and dark colored. They are used in the manufacture of sail cloth, carpet warp, and other products where strength and durability are of primary importance. Manila hemp is prepared from the outer sheath of the stems of the abaca. Manila fiber waste is used in papermaking, especially where strength and toughness are required.

Jute fibers are obtained by retting or maceration. They are yellowish-white, soft, lustrous, and without great strength. They are used in the manufacture of burlap, twine, and as a backing for linoleum. Their principal disadvantages are lack of durability, lack of moisture resistance, and brittle nature.

Fibers Produced from Whole Stems.

Fibers of this type are derived from the entire stems and include materials such as straw, bamboo, esparto, rushes, bagasse, cornstalks, canes, papyrus, rice hulls, and many others. The uses they are put to are varied and include pulp and papermaking, wallboards, insulating materials.

Woods.—While almost any fibrous raw material can be reduced to a pulp, no source of cellulose has been found to equal wood when used for the manufacture of paper. Wood cellulose occurs in association with the hemicelluloses, which are structurally related, and with lignin. The wood is first subjected to slashing and debarking, whether it is to be processed as a chemical or mechanical pulp. Lignin separation is accomplished by treating with sodium bisulphite and sulphurous acid or with caustic soda. Industrially, the manufacture of pulp is distinct from the papermaking industry. The pulp plants will generally be situated near the source of raw material, in forests; whereas the manufacture of paper generally takes place near the market. Wood contains between 60 and 65 per cent cellulose, 20 to 25 per cent lignin, and smaller amounts of pentosis waxes, gums, and ash. Wood in various forms such as woodflour is used in impregnated and molded plastic compounds.

PRODUCTS

Chemical Cotton.—The raw cotton linters are cooked with steam in a rotary digester with a dilute caustic soda solution. The digester pulp which is gray in color is then washed and bleached with calcium hypochlorite solution, using sulphuric acid to accelerate the process and reduce the ash content. The white bleached pulp is washed, freed from foreign matter, and sent through rubber-covered rolls, where the excess moisture is squeezed out. The lumpy pulp is then pulled apart, dried in a tunnel drier, and the loose linters are baled for shipment. The chemi-

cal cotton consists of 98 per cent alpha cellulose. To manufacture sheet cellulose for use in viscose manufacture, the bleached cellulose is blended with several batches and sent to a "beater." The beating continues for several hours and works mechanically on the durable water-resistant wall of the cellulose fiber, breaking the wall down and allowing the inner fibrils to be exposed. The fibrils absorb water, swell, and expand. Where necessary, sizing and other material are added at this point.

The suspended cellulose is then charged to a conical or disc-type refiner, where the clusters and coarser particles are separated from the finer ones and reduced in size. The suspension is diluted with water, passed through a rotary shaking screen and, if a high-grade product is desired, through a centrifuge where impurities are removed. The suspension next passes to a Fourdrinier type of machine where it is formed into sheets.

Pulp and Paper.—Wood pulp is manufactured by the following processes: mechanical pulp, sulphate pulp, soda pulp, and sulphite pulp.

Mechanical pulp is obtained by grinding with water, screening, and concentrating in thickeners.

Sulphate or kraft pulp is made by digesting wood chips with sodium sulphide, caustic soda, and cooking with live steam. The resulting pulp is washed, screened, filtered, and concentrated. It is next bleached, washed, and rethickened and pressed into sheets which are folded into bundles and shipped to the paper mills. The soda pulp process is very similar to the sulphate process except that digestion is accomplished with a solution of sodium hydroxide in water.

In the sulphite process, sulphur dioxide dissolved in calcium or magnesium bisulphite is used.

Coniferous woods such as spruce, fir, and hemlock are used in the sulphite process; poplar, birch, chestnut, gum, and basswood are used in the soda process; coniferous woods are chiefly used in the sulphate process.

The conversion of pulp to paper is accomplished by first beating the pulp and adding alum sizing and bleaching materials. An aqueous suspension of the pulp is dehydrated on a screen and the resulting mat is squeezed between rollers to form a firm sheet. It may then be sent to a coating machine if a glossy surface is to be applied. Many variations from the above are practiced in the paper-manufacturing field.

Rayon by the Viscose Process.—Of the three processes for the manufacture of rayon, the viscose is the most important, as over 65 per cent of the cellulose base fiber is produced by this method. The finished rayon thread consists of smaller molecules than the original cellulose and possesses different physical properties.

The main reasons for its wide use are the inexpensive raw materials used, such as wood pulp, sodium hydroxide, carbon disulphide, sodium sulphate, and sulphuric acid.

Sheets of wood pulp are charged to a steeping press and soaked in an 18 per cent sodium hydroxide solution. The beta and gamma cellulose dissolve leaving the alpha cellulose which constitutes about 86 per cent of the original pulp.

After the excess liquor is drained off and further liquid removed by squeezing, the alkali cellulose is shredded and reduced to soft crumbs. These are aged and then charged into a horizontal iron drum mixer where a regulated amount

of carbon disulphide is added. The drum is rotated for several hours and the crumbs coagulate into small balls of cellulose xanthate. These are dissolved in concentrated sodium hydroxide and the product known as viscose solution results. This is blended with several other batches, aged for several days, filtered and de-aerated. The solution is forced under pressure through very small openings in spinnerets into the spinning bath. The diameter and number of holes are varied according to the type of yarn desired. The spinning solution which contains 9 to 11 per cent sulphuric acid, 15 to 20 per cent sodium sulphate, some glucose, and zinc sulphate regenerates the cellulose from the viscose solution in the form of filaments. The filament is washed, bleached, and dried. Cellophane manufactured by the viscose process is extruded through a thin slot into the coagulating bath and then washed, bleached, softened, and made moisture proof.

Rayon by the Cuprammonium Process.—The cellulose is dissolved in an ammoniacal copper hydroxide solution, diluted, and filtered. The solution is forced through a spinneret into a 5 per cent caustic soda solution which coagulates the filaments. These are stretched 40 to 60 per cent before entering a dilute sulphuric acid coagulating bath. The yarn is then washed, dried, and twisted.

Cellulose Acetate Rayon, Plastics and Film.—Cellulose acetate is not a regenerated cellulose and differs both chemically and physically from the other processed rayons.

The cotton linters are added to a mixture of acetic anhydride, acetic acid, and a catalyst such as sulphuric acid. Acetic acid is added, the solution aged, and then run into a large volume of water which serves to precipitate the cellulose acetate. The flakes are washed, centrifuged, dried, and dissolved in acetone, and the resulting solution filtered. It is forced through spinnerets into a rising current of warm air, and the cellulose acetate filaments are formed as the acetone evaporates. The economics of the process depend on the efficient recovery of chemicals used.

A transparent cellulose acetate film is manufactured by extruding the acetate solution through a narrow slit onto a drum.

Cellulose acetate can be injection molded, compression molded, or extruded to produce useful articles of many shapes and sizes. Plasticizers and dyes are usually mixed with the cellulose acetate flake prior to forming.

Cellulose Nitrate.—Treatment of cellulose with a mixed acid consisting of nitric and sulphuric acids results in a nitrated cellulose as represented by the following reaction:

The degree of nitration can be varied and this in turn determines the characteristics and application of the nitrated cellulose.

Nitrogen Per Cent	Soluble in	Industrial Application
10.7–11.2	Ethyl alcohol	Plastics
11.2–11.7	Methyl alcohol, ethyl alcohol, ethyl acetate, etc.	Artificial fibers, photo- graphic film
11.8–12.3	Amyl acetate, ace- tone, ester solvents	Lacquers, artificial leather, explosives
12.4–13.0	Acetone	Smokeless powders and explosives

Purified cotton linters and bleached sulphite pulp

are commonly used for nitration. Previously the chief raw material used was cotton linters; however, of late wood pulp has been used in increasing amounts.

Ethylcellulose.—Ethylcellulose is manufactured by treating cellulose as derived from wood pulp or cotton linters with a concentrated sodium hydroxide solution and then alkylating the alkali cellulose with ethyl chloride or sulphate. The ether formed is washed and further processed. Ethylcellulose is a plastic material finding application as a coating material particularly for wire insulation and it can be readily injection molded to produce a wide variety of useful products.

CELSIUS, sěl'si-ūs, the name of a Swedish family, several members of which attained celebrity in science and literature: 1. **MAGNUS CELSIUS**: b. in the old province of Helsingland 1621; d. 1679. He became professor of mathematics in the University of Uppsala and published two works on the antiquities of his native province; he was the discoverer of the Helsing runes. Besides mathematics and archaeology, he cultivated poetry with some success, and was so skilled in practical mechanics that he himself made all the scientific instruments he required in his astronomical observations. 2. His son, **NILS CELSIUS**: b. 1658; d. 1724; also filled the mathematical chair in Uppsala University. 3. **OLAF CELSIUS**, another son of Magnus: b. 1670; d. 1756. He early became famous as an earnest student of the Oriental languages and of botany. He was successively appointed to the chairs of Greek, Oriental languages, and theology, and filled the office of provost of the cathedral at Uppsala. Much of his attention was given to the study of runology. He was among the first to recognize the genius of Carolus Linnaeus, whom he liberally patronized. In 1745–1747 he published his voluminous work, *Hierobotanicon*, a description of all the plants mentioned in the Bible. 4. **ANDERS CELSIUS**, son of Nils Celsius, and the most distinguished of the family: b. Uppsala, Nov. 27, 1701; d. there, April 25, 1744. After his appointment as professor of astronomy at the University of Uppsala in 1730 he visited numerous observatories in Germany, Britain, France, and Italy. In 1733 he published at Nuremberg a collection of observations of the aurora borealis made during 1716–1732 by himself and others. During 1736 he took part in an expedition to Lapland organized under the auspices of the French Academy for the purpose of measuring a degree of the meridian. Louis XV of France granted him a pension for these services. In 1740 he supervised the building of an observatory at Uppsala, and he served as its director until his death. He read a paper before the Swedish Academy of Sciences in 1742 giving the first description of the centigrade or Celsius (q.v.) thermometer. Adoption of the Gregorian calendar was advocated by him. His works included *De observationibus pro figura telluris determinanda* (1738). 5. **OLAF CELSIUS** the younger was the son of Olaf Celsius (1670–1756) and cousin of Anders Celsius: b. 1716; d. 1794. In 1747 he became professor of history at the University of Uppsala, and from 1777 he was bishop of Lund. Among his historical works were biographies of Gustavus I and Eric XIV.

CELSIUS, in thermometry, is the scale, also known as **CENTIGRADE**, in which the inter-

val between the ice point and the steam point under standard atmospheric pressure is divided into 100 degrees. The term Celsius is analogous to the names Kelvin, Fahrenheit, Réaumur, and Rankine, used for other temperature scales, for it perpetuates the name of Anders Celsius (q.v.) who, in 1742, first proposed such a division. The Ninth General Conference on Weights and Measures, held in Paris during October 1948, adopted the designation degree Celsius in place of degree centigrade or centesimal, and on Jan. 1, 1949, the National Bureau of Standards, in common with other national laboratories in the United States, began to use it. While the bureau recommended that scientists and industrial workers elsewhere conform, it was not considered practicable to impose the term Celsius on those who preferred centigrade. See **THERMOMETER**.

CELSUS, Platonist philosopher, an antagonist of the Christian religion in the 2d century. He is believed to have been the same Celsus, friend of Lucian, to whom is inscribed Lucian's satirical sketch of the life of the noted imposter and pseudo-thaumaturgus Alexander of Abonotichus, entitled *Pseudomantis*. No work of Celsus has come down to us in its integrity or in its original form, but his *True Discourse* is in substance preserved for us in the eight books of Origen's computation of the arguments brought by Celsus against the truth of the religion of Christ. It was written at Rome in the latter part of the 2d century. Origen quotes textually long passages from the *True Discourse* in his work *Against Celsus*. From these passages it is seen that Celsus had accurate knowledge of the religious creed and practices, both of the Jews and Christians, and he skilfully puts in the mouth of a Jew his criticism of the life of Jesus as told in the Gospels. Celsus himself appears to have been an epicurean and a scoffer at the supernatural, while his Jew is a firm believer in miracle, but for all that he cannot accept the Gospel stories. He rejects the doctrine of the Incarnation of God, and reports a scandalous story of an amour which he offers as a substitute for the evangelists' narrative; and the fact Origen quotes the passage containing this shockingly blasphemous suggestion (as it must have been regarded by him) is evidence that the Christian polemist is dealing fairly with his antagonist. According to Celsus, Jesus once visited Egypt and there learned the art of the jugglers; in his own country he easily won reputation as a wonder-worker, even a god. By his jugglery he might have made the multitude present at his immersion by John in Jordan believe that they heard a voice from heaven. If he was God, he would have made a better choice of apostles: why did he choose Judas? The story of the resurrection is self-contradictory. His death by crucifixion is undisputed and was a fact of public notoriety; if he rose from the dead, why did he not make the fact equally notorious and public? With such objections Celsus attacks the Christian faith in the first half of his work; in the second half he speaks in the person of a Grecian philosopher. Whatever is true and good in the Christian system exists already in the schools of philosophy; therefore, let the Christians abandon their narrow sectarianism and separatism and combine with all good and wise men in upholding the principles of good

government. Celsus then advances philosophical arguments against the credibility of the Christian mysteries, in particular the incarnation. God cannot assume a mortal body either in reality or in appearance only: not in reality, for that would be contrary to His nature; not in appearance, for that would be a fraud. But the idea of an incarnation of God is absurd: what could be gained by an incarnation? Certainly no advantage for God; but neither for men: do men know God better for seeing Him in bodily form? Did God a little while ago waken from sleep and resolve to save a few men from sin, leaving the mass of mankind to go down to hell? In his closing appeal he makes overtures for peace with the Christians, urging them to be good citizens and to retain their own private beliefs if they like, but to conform outwardly to the state religion.

Consult Froude, J. A., *Short Studies*, No. 4 (1883).

CELSUS, Aulus Cornelius, Roman writer on medicine who lived, probably, under the reigns of Augustus and Tiberius. He has been called the Roman Hippocrates, because he imitated the Greek physician, and introduced the Hippocratic system into Rome. He also wrote on rhetoric, the art of war, and agriculture. He is, however, best known as a medical writer. His work on medicine is an inexhaustible source from which other authors have drawn materials. Many editions of his *De Medicina*, comprising 8 books, have appeared throughout the years in several languages. The first edition was published in Florence in 1478. An English translation by James Grieve came out in 1756 (3d ed. Edinburgh 1837), and more recently a translation in English has appeared by W. J. Spencer (3 vols., Cambridge, Mass., 1935-1938).

CELTIBERI, sêl-tî-bêr'î, a people of ancient Spain, supposed to have arisen from a union of the aborigines, the Iberians, and their Celtic invaders. Various limits have been assigned to their country, which included probably all the north of Spain as far south as the sources of the Guadalquivir. They were divided into four tribes and were of the bravest and best of all the peoples of the peninsula. They excelled equally in cavalry and infantry. Hannibal subdued the Celtiberi, and they afterward passed under the Roman yoke. They revolted in 181 B.C., and were subdued by Tiberius Gracchus 179 B.C. Two struggles for independence followed, called respectively the first Celtiberian Numantine, and the second Celtiberian or Sertorian wars, in the latter of which they were finally vanquished; after 72 B.C. they do not again appear in history.

Consult Schulten, A., *Numantia*, 4 vols. (Munich 1914-1931).

CELTIC CHURCH, sêl'tîk or kêl'tîk, the name applied to the Christian Church in Great Britain and Ireland before the mission of Augustine (597) and which for some time thereafter maintained its independence by the side of the new Anglo-Roman Church. In Britain, the origin of the Christian Church remains in obscurity. There are sufficient records, however, to prove that throughout the 4th century there was a well-organized church in Britain which stood in constant touch with the rest of the church, particularly in Gaul, and considered itself an active part

of that body. In the 4th century, there are records of bishops, but for a hundred years after the mission of Saint Germain (Germanus) (429) nothing is heard of the church in Britain. The Anglo-Saxon conquest drove the Britons to the mountains of the west, where, in the 6th century, Christianity again became prominent. There were several minor differences between the Roman forms. The day of Easter, according to the former, followed the Eastern calendar; and there were also divergences in the methods of administering baptism. The coming of Saint Augustine in 597 introduced the Roman form of Christianity which gradually gained precedence over and absorbed the Celtic. In 777 its ascendancy was complete in Britain and south Wales. Still the Celtic Church continued farther north until 1172 when Queen Margaret introduced complete reforms.

In Ireland, there is much legendary history concerning the foundation of the church, which indicates that Christianity was brought from Britain to Ireland as the natural result of the close intercourse between those countries. The establishment of the church itself seems to have been an outcome of the first mighty wave of monasticism which swept from Egypt over Gaul and Britain and carried a number of half-Romanized Christians to Ireland. The first important figure in the history of the church in Ireland is Saint Patrick (389?-461), who converted the island and was most active in preaching and founding churches. In the region now known as Scotland, Saint Ninian, Saint Columba, and their fellow apostles established institutions which were monastic and missionary in nature. From Iona as a center, the movement soon embraced all of Northumbria. The Celtic Church there was finally fused with the Roman in 664; the Scottish and Irish churches lost their individual character in the same year, from which time their histories are identical with the Roman Church. See CULDEES.

CELTIC LANGUAGES. The Celtic languages form the most westerly group of the Indo-European family of languages, all of which seem to descend from a common origin, or are at least characterized by a closely related system of phonetics and morphology, as well as by a common vocabulary and the same syntactical structure. The Celtic languages, which have been spoken by different branches of the Celtic peoples (q.v.) from prehistoric times to the present day, belong to the so-called *centum* group of the Indo-European dialects. The *centum* group to which belong Italic, Germanic, Greek, Venetic, Illyrian, as well as Tocharian and Hittite, have preserved the Indo-European palatal consonants as occlusives, while in the so-called *satem* group (Albanian, Armenian, Balto-Slavic, Indo-Iranian) they became sibilants. So we have in

Welsh *cant* (hundred) as in Latin *centum*, as opposed to Avestic *satam*, going back to an Indo-European **kṛntóm*.

Phonetic Characteristics.—The most notable phonetic characteristics which set off the Celtic languages from the other members of the Indo-European family are: (1) The dropping of the initial and intervocalic *p*: compare Latin *pater* with Old Irish *athir* (father); Gaulish *are-* (beside) and Irish, Welsh *ar* with Greek *πᾶρ, παρά*; Gaulish *ver-* (over), Irish *for*, Old Welsh *guor* with Greek *ὑπέρ*.

(2) The Indo-European medial aspirates *bh*, *dh*, *gh*, and *ǵh* have completely fallen together with the simple voiced stops: compare Old Irish *-biur* (I carry) with English (I bear), Latin *ferō*, Greek *φέρω*; Old Irish *-tiag* (I go) with Greek *στείχω*.

(3) The Indo-European labialized velar *gʷ* has become *b*: compare Old Irish *bó* (cow), Welsh *buwch* with Greek *βοῦς*, Sanskrit *gauh*; the change of the Indo-European labialized voiceless guttural *kʷ* and of *k + ʰ* to *p* is only found in Gaulish and Brythonic (see later discussion).

(4) The Indo-European vocalic *r* and *l* appear before stops and *r*, *l*, *m*, *n*, as *ri* and *li*: compare Gaulish *ritu-* (ford), Welsh *rhyd* with Latin *portus* (harbor), German *Furt* (ford); Gaulish *litanos* (broad), Old Welsh *litan*, Old Irish *lethan* (broad) with Greek *πλάτανος* (plane-tree).

(5) The Indo-European *ṛ* is changed to *i*: compare Gaulish *rīx* (king) Old Irish *rí* (king), Welsh *rhi* (prince) with Latin *rēx* (king).

(6) Indo-European *ō* is changed to *ā*: in final syllables to *-ā*: compare Gaulish *gnātos* (familiar), Old Irish *gnáth* (known), Welsh *gnaeth* (customary) with Latin *(g)nōtus*, Greek *γνώτός*; compare Old Irish *cú* (dog), Welsh *ci* with Sanskrit *śvā*, from Indo-European *kūō(n)*.

(7) Indo-European *ei* has become *ē*: compare Gaulish *dēuos* (divine) Old Irish *día* (god), Old Welsh *duiu-tit* (god-head) with Latin *dīvus*, god(like), Sanskrit *dēva-h*.

Morphology.—The Old Celtic morphology must have been very archaic: the neuter gender as well as the dual of the noun were preserved, while the verb shows a similar rich inflection like Greek and Sanskrit. Celtic and Indo-Iranian are the only Indo-European languages which have preserved the distinction between masculine and feminine gender in the numerals *three* and *four*: Old Irish masculine *trí* (three), Welsh and Breton *tri*, feminine Old Irish *téoir* (Indo-European **tisores*). Middle Welsh and Breton *teir*, Sanskrit masculine *tráyah*, feminine *tisráh*; Old Irish masculine *cethair* (four), Welsh *pedwar*, Breton *pevar* (Indo-European **k^uetuores*), feminine Old Irish *cethéoir* (Indo-European **k^uetesores*), Middle Welsh *pedeir*, Breton *peder*, Sanskrit masculine *čatvараh*, feminine *čátasrah*.

The closest analogies, however, are found between Celtic and Italic. It is true, the passive and deponent formations in *-r* are found not only in Celtic and Italic, but also occur in Venetic, Indo-Iranian, Phrygian, Armenian, Hittite and Tocharic. The genitive singular in *i* of masculine and neuter *o*-stems is also found in Venetic and Messapic (Illyrian); but the assimilation of an initial Indo-European *p-* to a following *k^u* is

an innovation, only found in Italic and Celtic: Indo-European **penk^ue* (five) becomes Latin *quinque* and Old Celtic **quenque*, hence Old Welsh *pimp*, Breton *pcmp*, Old Irish *cóic*. The superlative in **-samo-* is only found in Celtic and Italic: Gaulish *Belisama* (the very shining one), Old Welsh *hinham* (oldest, from **senisamos*), Old Irish *nessam* (nearest), Oscan *nessimas* (nearest; nom. pl. fem.), Latin *maximus* (greatest). Both languages had subjunctives in *-ā* and *-s* under similar morphological and phonetic conditions; both have (independently) created a *b*-future: Latin *amābō*, Old Irish *léiciub* (I shall leave); and both formed verbal nouns in *-tiō(n)* and used the old verbal adjective in *-to-* to form a passive preterite.

All those morphological agreements point to very old relations between Celtic and Italic. A close neighborhood in prehistoric times would be sufficient to explain them. On the other hand, the vocabularies of both languages, though they show some interesting agreements [Old Irish *dí* (of, from) = Latin *dē*; Old Irish *den* (strong) = Latin *bonus* (good), archaic *duenos*], are not so similar as to justify the assumption of a former genealogical Celto-Italic unity.

The vocabulary of Celtic and Germanic shows far more identical words: Gothic *aiths* (oath) = Old Irish *oeth*; Gothic *rūna* (secret) = Old Irish *rūn*; Gothic *freis* (free) = Welsh *rhydd*; Gothic *haiþi* (field), English *heath* = Welsh *coed* (wood); Old English *wudu* (wood) = Gaulish *vidu-*, Old Irish *fid*. Many of these words may be Celtic loans in Germanic, as for certain Gothic *andbahts* (servant), hence German *Amt*, from Gaulish *ambactus*; or Gothic *reiki* (empire) from Gaulish **rigion*. But the morphology of both languages is very different. This points to rather late relations between Celts and Germans, after their morphology had already been fixed.

The numerous common religious terms between Celtic and Indo-Iranian are rather to be explained as survivals from the Indo-European past, while the many agreements between Celtic and Baltic and Slavonic vocabulary may be due to the wanderings of the Urnfield people (see CELTIC PEOPLES).

CELTIC LANGUAGE GROUPS

The Celtic languages fall into 2 main groups: Goidelic (called today Gaelic) and British (also called Brythonic). This cleavage already appears on the earliest Celtic monuments. *Ancient Goidelic* is characterized by (1) the preservation of Indo-European *k^u* and *k + ʰ* as *qu*: *equos* (horse); (2) the change of Indo-European sonant *m*, *n* before stops to *em*, *en*: **kenton* (hundred); (3) the preservation of initial *sr-*: *srutus* (stream).

Ancient Brythonic is characterized by: (1) the change of Indo-European *k^u* and *k + ʰ* to *p*: *epos* (horse); (2) the change of Indo-European sonant *m*, *n*, before stops to *am*, *an*: *kanton* (hundred); (3) the change of initial *sr-* to *fr-*: *frutus* (stream).

Continental Old Celtic (often called *Gaulish*), mostly belongs to the Brythonic group, but the language of the Celtiberians and of some other Spanish Celts can be shown to have belonged to the Goidelic group. All we have left of Gaulish, as spoken in Gaul, Spain, northern Italy, and the rest of Europe, are about 60 inscriptions: some in the North Etruscan alphabet of the 2d

The asterisk (*) indicates that this particular word form is conjectured and reconstructed.

century B.C.; some in the Greek alphabet or in the Latin alphabet of Roman imperial times, to which have been added over 60 graffitos from La Graufesenque (Aveyron) with lists and accounts of potters. The Goidelic inscriptions of the Celtiberians are mostly in Iberic alphabet.

Apart from Celtic words recorded by classical writers, there have been preserved a large number of personal and place names in literature, on coins, and on Greek and Latin inscriptions all over Europe. Celtic place names are found as far east as the Dniester (*Carro-dūnon*, Wagon-fortress), the Dobruja, Galatia in Asia Minor, and as far north as Westphalia. They are mostly compounds with *-dūnon* (fortified place), *-brigā* (height, fortress), *-magos* (field), *-ialon* (clearing), or derivatives from personal names with the suffix *-ācon* (Latin *-ācum*). Though there must have been dialectic differences in such a huge territory, almost no trace of such appears in the numerous place names and proper names on inscriptions; St. Jerome tells us that the speech of the Galatians in Asia Minor bore a strong resemblance to the language he had heard spoken in the neighborhood of Trier (386 A.D.).

No written trace of the rich oral Gaulish literature has survived. More than 200 Celtic words have been preserved in the Romance languages, mostly terms referring to agriculture, peasant life, and plant names. Celtic speech seems to have died out in Gaul in the course of the 5th century A.D., but probably survived much longer in the mountainous parts of Switzerland. Celtic idiom spoken in Brittany today is not a survival of Gaulish but the language spoken by those Brythons who fled from the southwest of England to Armorica in the 5th and 6th centuries of our era, being driven out by the Saxons.

Insular Celtic, like continental Celtic, is divided into two groups: Goidelic and Brythonic, but their divergences are much greater than on the Continent. The chief differences developed only from the 6th century A.D. onward, so that today an Irish speaker could not make himself understood to a Welsh speaker, while in St. Patrick's time mutual communication could not have been difficult.

Goidelic or Gaelic.—The name Goidelic comes from the ancient name of the people, the *Goidil*, known to the Romans by the name of *Scotti*. The territorial subdivisions of Gaelic are: (1) Irish or Irish Gaelic (native *Gaedhealg*) in Ireland; (2) Scottish Gaelic (native *Gáidhlig*), sometimes called Erse (= Irish) in the northern and western Highlands of Scotland and the adjacent western islands where it was introduced by the Irish settlers (called in Latin *Scotti*), from about the 6th century A.D.; (3) Manx (native *Gailck*), the language formerly spoken in the Isle of Man, now almost extinct. Linguistically these are really nothing more than dialects of one language, Old Irish; we possess no monuments of Scottish Gaelic and Manx in the oldest period: Until the end of the 18th century, though spoken Irish and Gaelic had diverged to a considerable extent, the same literary language as passed current in Ireland continued to be employed by Scottish writers.

Irish.—Of all the Celtic languages, Irish is by far the most important because of its wealth of archaic features and abundance of linguistic material. The language of some of the Ogam, q.v. (Ogham) inscriptions (5th to 7th century A.D.) is almost as archaic as that of Continental

Celtic. Altogether there are about 370—short inscriptions on gravestones and boundary stones, almost exclusively containing proper names—most of which have been found in the southern half of Ireland. Those found in Britain (48), chiefly in Wales, are due to colonists from southern Ireland. The 16 "Pictish" inscriptions in Scotland are written in an unknown language. The Ogam alphabet consists of 1-5 strokes or notches scored on either side of the edge of an upright stone, originally no doubt on wooden staves.

The literary tradition begins with Old Irish, written in Latin cursive script, from about 600 to 900 A.D. Much Old Irish linguistic material has been preserved, in slightly modernized form, in Middle Irish manuscripts. Middle Irish, distinguished from Old Irish chiefly by the weakening of vowels in unaccented syllables and the reduction of flexional forms, extends to about 1400. The language was not the popular language but rather that of literature; the literary classes had at their command a standard form of Irish which educated men understood everywhere. As the result of the English conquests there came about the dissolution of the standard literary language. From the 16th century a dialect with well defined characteristics was spoken throughout the southern half of Ireland. Northern Irish is subdivided into two lesser dialects, one of them in Connacht, the other (strongly influenced by Scottish Gaelic) in Ulster. Irish is still spoken in the southwest, west, and northwest of Ireland. In the mid-19th century 4 million out of 7 million persons spoke Irish as their mother tongue, of whom 1 million spoke only Irish. In 1952 the number of Irish speakers among a population of approximately 4,300,000 is only 740,000, most of whom are bilingual.

Scottish Gaelic.—Scottish Gaelic was differentiated from Irish chiefly on account of the strong Norse influence. The sound shifting of the voiced *b, d, g*, to the voiceless stops *p, t, c*, was accompanied by a change of the historic voiceless stops *p, t, c* which are, when initial, pronounced with a following strong aspiration, and when they follow the stressed vowel become the preaspirated occlusives *chp, cht, chk*, a curious parallel to the prehistoric Germanic sound shifting. In 1931, out of a total of 4,842,980, the number of Gaelic speakers was about 137,000, 7,000 of whom spoke only Gaelic, to which may be added 30,000 bilingual speakers in Canada.

Manx.—Manx stands in a much closer relation to Scottish Gaelic than to Irish. It is written in a kind of phonetic spelling, based on Anglo-Scottish orthography. Its most distinctive feature is a peculiar stress system. Many disyllabic words with final long syllable shifted their stress to the second syllable as a result of Anglo-Norman influence; the same happened in Southern Irish. Somewhat later long terminations of those words which had escaped the accent shift were shortened, probably under the influence of Scottish Gaelic. The Manx vocabulary contains a fairly great number of Norse and English loan words. In 1875 there were still 12,340 people out of a population of 41,048 (exclusive of the capital, Douglas) who used Manx as their everyday language, among them 190 who spoke nothing but Manx. In 1952 there were only about 20 people who still could speak Manx.

British or Brythonic.—The term British or Brythonic comes from *Brittones* (Welsh *Bry-*

thon), a byform of Latin *Britanni*, the inhabitants of the Roman province *Britannia*. It comprises: (1) Welsh (native *Cymraeg* from *Cymro* meaning "fellow countryman"), so called from the Celtic people, the *Volcae*, whose name was extended by the Germans to all their western neighbors, in this case to the inhabitants of Wales; (2) Cornish (native *Kernewek*), the language of the Cornwall Peninsula, extinct since the end of the 18th century; (3) Breton (native *Brezhonek*), the several dialects of the Breton Peninsula.

Welsh.—Welsh is the most important language of the Brythonic group. Old Welsh (from 800 to 1100 A.D.) is known to us almost entirely by means of glosses, isolated words and proper names, but some Old Welsh texts have been preserved in Middle Welsh dress. Middle Welsh (from 1100 to 1500) is much more simplified than Old or Middle Irish. There remain only faint traces of case forms (mostly in the formation of the plural), the dual and the neuter gender, and the inflexion of the verb does not show as many archaic traces as that of the Irish verb. Spoken Welsh may be divided into North and South Welsh, each of which is further divided into two groups. In 1931 out of a total population of 2,472,377, there were over 900,000 Welsh speakers of whom 98,000 spoke only Welsh.

Cornish.—Cornish which stood in a much closer relation to Breton than to Welsh, can be divided into Old Cornish, known only by glosses and proper names (from 900 to 1100), Middle Cornish (until 1600), and Late Cornish.

Breton.—Breton is divided into Old Breton (from the 9th to the 11th century), known likewise only by glosses and proper names, Middle Breton (until the 16th century), and Modern Breton, which is composed of four chief dialects of Léon, Cornouailles, Tréguier and Vannes. The last named differs greatly from the others, chiefly by preserving the old British stress on the former penult, which is now, after the loss of the final syllables, the final syllable.

Pictish.—Pictish, the language of the Picts (Latin *Picti*) in the north of Britain, has left scarcely any traces beyond 16 "Pictish" inscriptions in an unknown language, and a few proper names, some of which seem to be non-Celtic, and some Goidelic and British. It is not impossible that a Goidelic dialect was spoken in Pictland before the coming of the Scots.

INSULAR CELTIC VARIATIONS

Differences Between the Goidelic and Brythonic.—The chief differences between insular Goidelic and Brythonic are: (1) While Old Celtic (Gaulish) seems to have preserved the free Indo-European accent, as shown by the development of Gaulish place names in French (*Némausus*: French *Nîmes*; *Tricasses*: French *Troyes*; but *Bituriges*: French *Bourges*; *Eburóvices*: French *Eureux*), the accent rules in insular Celtic have become mechanical. In Irish the stress always fell on the first syllable, causing the loss of vowels in post-tonic syllables, but in Brythonic it fell on the penult before the loss of final syllables. Afterward it was again shifted to the new penult: compare Old Irish *Eriu* (Ireland) from Goidelic *Élcríú*, genitive *Ércnn* from **Éveríónos*. The same **Éveríónos* became in Welsh *Iwérdon*.

(2) Initial *s-* was preserved in Irish but became *h-* in Brythonic: compare Gaulish *senos* (old), Old Irish *sen*, with Welsh and Breton

hen. The treatment of the *s-* groups also varies a great deal in Irish and Brythonic.

(3) In Irish the old Old Celtic voiceless stops *t* and *k* became voiceless spirants *th* and *ch* in intervocalic position, while in Brythonic the old Celtic intervocalic stops *p*, *t*, *k*, became voiced stops *b*, *d*, *g*: compare Gaulish *catu-* (battle) with Old Irish *cath* and Welsh *cad*.

(4) Old Celtic *j* and *w* are lost in Irish, but preserved in Brittonic: compare Old Celtic **jewnkos* (young) with Old Irish *óac* (archaic *óéc*) and Welsh *icuanic* (young).

(5) The vowels of accented syllables are better preserved in Goidelic than in Brittonic: compare Gaulish *dānon* (fort) with Old Irish *dún* and Welsh *din*; Gaulish *oinos* (one) with Old Irish *oin*, *óin*, and Welsh Breton *un*.

(6) Owing to the contact with the Romans there were not only many more Latin words introduced into Britain than into Ireland, but the Brythonic languages became much more simplified in their grammatical structure and preserve far less archaic traits than Goidelic.

Differences from Other Indo-European Languages.—While Gaulish syntax does not seem much different from that of the other Indo-European languages, as far as we are able to judge from the few inscriptions, the general character of insular Celtic seems completely different. (1) While the autonomy of the single word seems especially characteristic of Indo-European, it is rather the group of closely connected words that forms the principal unit in insular Celtic. This explains why the same rules which govern the fate of intervocalic consonants or of nasals + consonants are also applied to initial consonants within certain groups of words in accordance with the original endings of preceding words; compare Old Irish *fer cáech* (a blind man), Old Celtic **riros caicos*; genitive *fir chaich*, Old Celtic **riri caici*, where the initial *c* is treated like intervocalic *c* if the preceding noun ended in a vowel. Thus the original endings still exercise their influence upon the initials of a following word, long after the endings themselves have been lost. Without these changes, so-called initial mutations, there would be no such thing as syntax in Celtic. They have taken the place of the original word inflection, which has thus been supplanted by so-called group inflection, characteristic of some non-Indo-European languages, like Basque and most languages of the Caucasus. The same group inflection appears in verbal forms which incorporate not only a pronominal object, a construction also found in some Indo-European languages, but at the same time a pronominal subject as well as relative and local particles; as for example, Old Irish *amal as-i-n-d-hcir-som* (as he says it), from earlier **eks-is-en-ide-e(d)-beret-somos*, literally (in-the-way out-he-in which-here-it-brings-he).

(2) The fixed position of the verb at the head of the sentence which is not obligatory in any other Indo-European language, is likewise found in Berber, Egyptian, and Semitic.

(3) The Indo-European languages are characterized by a highly subjective verb which treats normally all events as actions; they also have developed a nominative case as the distinct expression of the subject as such. In insular Celtic the agent (logical subject) of the action which the verb expresses, very often appears in an impersonal, passive construction, also found in Egyptian, Berber, Basque, and in many Cau-

casian and Arctic languages (Eskimo). Note particularly the passive construction even of the verb *to be*, as in Old Irish *is di Ult(a)ib dom* (it is of the Ulstermen to me = I am an Ulsterman).

(4) The insular Celtic system of tenses and aspects, particularly the use of the progressive (periphrastic) tenses to denote the aspect (also taken over by English), is certainly not Indo-European but has parallels in Basque, Egyptian, and Berber.

(5) There is no present participle, its function being discharged by the verbal noun, as in Egyptian and Berber.

(6) The so-called inflected prepositions (Old Irish *dom*, to me, *duit*, to you, *dó*, to him) have their exact parallel in Berber, Egyptian, and Semitic. Prehistory and anthropology show the existence of more than one pre-Celtic element in the British Isles: remainders of the Paleolithic inhabitants of western Europe, many traces of a widespread Arctic Mesolithic culture, Mediterranean invaders from northwest Africa (the bearers of Megalithic culture) and finally, during the Bronze Age, Dinaric brachycephalic immigrants from Spain, hailing ultimately from the Middle East, the so-called bell-beaker folk. See also CELTIC LITERATURE.

The great importance of Celtic linguistical studies lies in the fact that here we have an excellent chance of studying the effects of race and language blendings. It is at last being realized "that the Celtic world commands one of the chief portals of ingress into the pre-Aryan foreworld, from which it may well be that we modern Europeans have inherited far more than we dream."¹

Former Professor of Celtic, University of Berlin;
now in Zurich, Switzerland.

CELTIC LITERATURES. Though we have no remains of the rich literature of the continental Celts, our knowledge of their art and their national character, as described by the classical writers, gives us some idea of the literary characteristics and shows that in many respects it must have resembled that of the insular Celts.

The chief characteristics of Celtic literature are as follows:

(1) The Celtic nations stand almost alone in the fact that they did not employ poetry for epic narrative. The verse form was reserved for the use of lyric poetry. Prose was the natural vehicle for Celtic narrative. When the French Arthurian epics became known to the Welsh, they were changed from verse into prose. On the other hand, the prose form of the Teutonic sagas and French romances is due to Celtic influences.

(2) There is no Celtic drama, but the prose epics are often interspersed with dialogues in verse form.

(3) Celtic poetry is frequently deficient in the architectonic quality, in the sense of structural unity. The poets do not seem to have the faculty to produce large, continuous compositions, but devote their attention to the harmonious detail rather than to the whole. In the longer poems or tales, image is added to image, fancy piled on fancy, but we feel the want of any organic progression of thought and feeling. They are masters of detail, just as the Celtic artists were masters in decoration and handicraft, but

¹ John Rhys in *Proceedings of the British Academy* I (1903), p. 60.

did not produce great representative works of art.

(4) The devotion to detail explains why, in so many beautiful poems, we do not have elaborate or sustained description, but rather a succession of impressionistic pictures and images. To the poets the half-said thing is dearest; they avoid the obvious and the commonplace. A thousand years later this "impressionism" would be rediscovered in France; that this happened on old Celtic soil is certainly no mere coincidence. The Celts are distinguished among the Indo-European peoples by high mental excitability, accompanied by quickness and mobility of thought. Also their language shows a tendency to break thought into smaller parts than does any other Indo-European language. These quick transitions of thoughts and feeling, which characterize the Celts, had impressed the Greek and the Latin writers.

(5) Celtic nature poetry stands quite alone in medieval European literature. Nowhere else do we find such a sensitiveness to nature's various moods and the capacity of bringing human moods into relation with those of nature. It is sentimental and highly imaginative, but never rationalistic. Often nature is described with a loving fidelity which has no object but itself.

(6) The irrational plays a far greater part than in other literatures. Celtic literature is full of tales of magic and the supernatural; the distinction between natural and supernatural had not yet been clearly drawn. Dreams and visions belonged to the stock of the poet's repertoire, and even today some of the folk stories are actual daydreams. The Celtic storyteller had a vastly greater power of imagination and a much more subtle sense of the uncanny than the storyteller in other European countries. The fantastic exaggeration found in early epic tales was sometimes done for the fun of the thing, but by no means for this reason alone. The strong sense for the irrational had long been a characteristic of continental Old Celtic art.

(7) Though the Celts appear in their literature as a warlike people, gay and sensuous, fond of bright colors and eager for life, there is, after all, a vestige of truth in the myth of the "Celtic twilight," in which the Celts appeared to the rest of Europe as a result of the forgeries of James Macpherson (q.v.). In the earliest Celtic poems we occasionally find an intense, passionate yearning for that which is not possessed, for dead friends, for vanished youth, for satisfaction which life can never give. But those elegies form merely a small part of the early Celtic literature. Only in modern times has the tragic fate of the Celtic peoples, who often had to struggle for their bare national existence, caused a change. Political persecution and social depression could not be without effect upon the literary production.

(8) While poets of other nations usually endeavor to translate the remote into terms of the present, Celtic poets invariably depict the remote as remote, producing in this way the sense of mystery and atmosphere of glamour found in so many Celtic romances.

Irish Gaelic Literature.—This division of the Celtic literatures is treated in a separate article under the heading **GAELIC LITERATURE**.

Scottish Gaelic Literature.—Until the beginning of the 18th century the literary language of the Scottish Highlands was the Gaelic of Ireland. The classic Gaelic poetry is the same in both

countries. The subjects treated are about identical, since the literature of Scotland in its earlier stages drew its inspiration and themes from the motherland. The official poets and men of learning of the Gaelic chiefs went to Ireland for their bardic training. The family bards occupied an honored position in the social system; they kept alive the pride of race and ministered to it, especially by panegyrics.

We get the first glimpse of a special Scottish Gaelic tradition in the oldest and most precious collection of poems, known as the *Book of the Dean of Lismore*, written between 1512 and 1529 and collected by Sir James Macgregor, dean of Lismore in Argyll. Though the subject matter of the poems does not differ much from the contemporary Irish literature, the curious phonetic orthography and stylistic peculiarities enable us to form a fair idea of the dialects spoken in Scotland. The most important part of the collection consists of 28 *Ossianic Ballads*. Thus the dean's book gives clear evidence that already at that time Ossianic poetry was recited and known in Gaelic Scotland, very similar to the type known from later tradition. The use of the ballad for epic purpose originally was foreign to the Celtic poetic genius; no doubt its adoption was due to Viking influence in both Ireland and Scotland.

Toward the close of the 16th century, owing to the decay of the trained professional poets and of the bardic organization, a new school of poets arose. The complicated syllabic classical meters were abandoned and new meters came into existence. This modern poetry was usually regulated by stress, each line having a fixed number of stressed syllables—in other words, a certain rhythm. The foremost representatives of this new mode were Mary Macleod (in Gaelic, Mairi Nighean Alastair Ruaidh, c.1615–1707) and John Macdonald (Iain Lom, c.1620–1710).

More than 130 poets are mentioned between 1645 and 1830, many of them men of really great ability. Their language was the current Gaelic of their day. While the classic poetry was addressed to the aristocracy, the modern poetry was addressed to the people. The greatest original genius was Alexander Macdonald (Alasdair MacMhaighstir Alasdair, c.1700–1760) who struck an entirely new note in Gaelic literature. In his descriptive poems he gave expression to that intimate love of nature, as found in early Irish lyrics. In 1741 he published the first Gaelic vocabulary, the first book printed in Scottish Gaelic. Other poets of great merit were Duncan Bán MacIntyre (Donnachadh Bán, 1724–1812) and the great satirist, Robert Mackay, called Rob Donn (1714–1778). The greatest writer of hymns and sacred poems was Dugald Buchanan (1716–1768). The poets of the new school were born, not made. Their poetry is spontaneous; it has the notes of freedom and sincerity, and great beauty of form; the style is direct and clear. The poets delight in manly vigor and beauty, in prowess in war and hunt, in singing of festivity and of music. There is no trace of "Celtic mysticism" or of "Celtic gloom," not even in the lyrical outburst which followed the Forty-five (the Jacobite uprising in 1745), when the Gaelic people were left dependent on a foreign—and to them distasteful—culture. The dominant note in it is emphatical personal loyalty to their beloved prince. In the dawn of the 19th century every district in the Highlands still had its native poet,

but today not many bards of high reputation are left.

James Macpherson (1736-1796), the well-known forger of Ossianic ballads, has no place among the Gaelic poets, because his Gaelic texts are mere retranslations from the English and full of offenses against idiom, being written in an unnaturally strained language. Yet he was an Anglo-Celtic poet of real genius and, after all, an heir to the ancient Celtic bards. Though his overflowing sentimentality corresponds rather to the general tendency of the 18th century than to the Celtic character, there is a decided Gaelic atmosphere in his work and his sentimental nature poetry is doubtless an old Celtic heritage. His great mission was to make people aware of the existence of Celtic tradition, and the Ossianic revival led to the diligent collection of Ossianic poetry in the Highlands and the Isles. The effect of this was of lasting importance in the salvation of this tradition from oblivion.

Despite a total absence of printed books, the Scottish Gaels were in possession of a rich oral literature, dating back at least eight or nine centuries, still kept alive and familiar to the people. The ballads, mostly derived from older prose stories, are concerned chiefly with the deeds of the Irish hero Finn and his heroes, the foremost among them being Ossian and Oscar; very often they are represented as fighting against invaders from overseas. Since about the 12th century the Vikings often have taken the place of older supernatural foes. Moreover, the older Irish cycle about the heroes from Ulster is not absent, but it was not popular in Scotland. No less interesting than the Ossianic ballads (and far more important to the folklorists) are the numerous charms and incantations, collected by Alexander Carmichael (1832-1912) in his immortal *Carmina Gadelica*.

Unfortunately there is not much Gaelic prose literature worth mentioning. The whole Gaelic Bible appeared in 1807; the earlier editions of 1767 and 1783 show too much Irish influence. But we have a great amount of valuable Gaelic folk tales published (see *Bibliography*), not to mention various collections of proverbs.

Manx Literature.—There is no early literature extant in Manx. Of the many Ossianic poems known among the Manx people only one fragment (and that possibly of an earlier period) has been preserved. Most of the existing literature of native origin consists of ballads and carols, locally called carvels. Only a small part of these has been published. There is, besides, a fair amount of folklore, tales, and proverbs.

The translated literature is almost entirely of a religious character. The earliest book known to have been written in Manx is a translation of the Book of Common Prayer, written between 1625 and 1630 (but published only in 1895). The first printed book is *The Principles and Duties of Christianity* (1699) by Bishop Thomas Wilson. The complete Old Testament appeared in 1772 and the New Testament in 1775.

Among nonreligious translations may be mentioned a paraphrase of portions of Milton's *Paradise Lost* by Thomas Christian (1794) and *Aesop's Fables* by Edmund Faragher (1901).

Welsh Literature.—Welsh early poetry is found mainly in four manuscripts commonly called *The Four Ancient Books of Wales*, namely the *Black Book of Carmarthen*, the *Book of Aneirin*, the *Book of Taliesin*, and the *Red Book*

of *Hergest*, all written after the close of the 12th century. Most of the poems in these manuscripts are attributed to four poets: Aneirin, Taliesin, Myrddin (the Merlin of romance), and Llywarch Hen. Those are called *cynfeirdd* (early poets). Metrically their work shows the main characteristics of Welsh syllabic verse. The rhythmic effect is attained chiefly by the use of internal rhyme and of consonantal correspondences. The first three poets belong to the "Men of the North," the British tribes who, until the mid-7th century, owned the south of Scotland and the northeast of England. The *Gododin* (*Gododdin*) of Aneirin, a poem on the Battle of Catraeth (probably modern Catterick), about 600 A.D., is not a narrative poem, but rather a succession of lyrical laments on the disastrous effects of the battle. Though largely modernized, the *Gododin* and several historical poems attributed to Taliesin show distinct traces of direct copying from a 9th-century original. It has been claimed on internal evidence that the *Gododin* is actually the work of Aneirin (c.600). The Myrddin poems, as well as his name, are late and spurious. Llywarch Hen is not the author of the poems attributed to him, but merely the chief character of a lost saga, produced about 850 in Powys or mid-Wales. The poems are steeped in magic and have a prevailingly elegiac quality.

The next period, that of the *gogynfeirdd* (rather early poets), from about 1150 to 1350, is the time of the bardic court poetry. The bards were court officials with closely defined duties and recognized privileges. Their tendency to preserve the exclusiveness of their caste by multiplying the difficulties of their craft led to an exaggerated formalism and the substitution of verbal ingenuity for passion and imagination. Yet their poetry often succeeded in expressing not systematically but rather by suggestion the whole gamut of their emotions. Noun is piled on noun and adjective on adjective, so that one must feel their poetry rather than understand it.

The father of modern Welsh poetry is Dafydd (Davydd) ap Gwilym (c.1325-1385),* the greatest poet produced by Wales. He broke the tyranny of the bardic schools and freed the poetic language from the fetters of conventional archaic diction by writing in the ordinary language of his educated countrymen. He introduced popular fresh themes and established the new metrical form called *cywydd*. His love poems are derived from Provençal poetry through the channels opened by the *clerici vagantes* (wandering scholars), but are far more realistic. The highest summit of his poetic art he attains, however, in his nature poems.

Unfortunately the authority of the bardic schools soon re-established the old formal strictness, though the *cywydd* remained and flourished. After centuries of decadence and the final collapse of the bardic organization, the Methodist revival of the 18th century, which produced masterpieces of modern hymnology, and the literary renaissance, which was in strong opposition to it, led to an extraordinary outburst of poetry. Here belongs Ceiriog (pen name of John Ceiriog Hughes, 1832-1887), one of the chief lyric poets of Wales.

From about 1850 the accentual free meters gained more and more ground. The "new poet" school was inaugurated by Sir John Morris-Jones (1864-1929) with his excellent translations from

* Some sources give c.1340-1400.

Heine. W. J. Gruffydd (1881–), one of the first to revolt against the tyrannical puritanism, has written poems of singular beauty. T. Gwynn Jones has shown that the old tradition can answer to any demand made upon it. His translation of Goethe's *Faust* is a masterpiece.

R. Williams Parry and Cynan are among the best. Modern Welsh lyrical poetry occupies an honorable place among the literatures of the great nations of Europe.

The gift for gnomic poetry and fondness for the epigram have been characteristic of Welsh literature since the 12th century. There are hundreds of examples of the *englyn* (a four-line stanza), many of them comparable to the Greek epigram at its best. Among the countless folk songs must be mentioned the anonymous *penhillion* (stanzas for singing to the harp), often quite heart-rending in their perfect simplicity. In these, as in many other poems of the 19th century, we find for the first time a note of melancholy, that "nostalgia of the infinite," due to the hopeless social conditions and the influence of Calvinistic theology, which has often been quite wrongly ascribed to the Celts as such.

There was no Welsh drama until the 19th century, when this genre made a promising start. The interludes or miracle plays of Twm o'r Nant (1729–1810) hardly deserve that name.

Welsh prose begins with the *Laws of Howel* (*Hywel*) *Idda* (10th century). The vast body of Arthurian legend was widely known on the Continent even before Geoffrey of Monmouth wrote in Latin the *History of the Kings of Britain* (1135). The sources of the Arthurian verse epics of the French poet Chrétien de Troyes (1130?–1180) must have been Welsh and Cornish documents as well as spoken narratives. The earliest attempt at turning prose to artistic purposes is found in the *Four Branches of the Mabinogi*, preserved in the *White Book of Rhydderch* (c.1175). The first four tales (forming the *Mabinnion* proper) preserve Old British mythical traditions, partly influenced by Irish mythology; the others are Old British tales, referring to Roman times. British Arthurian tales, and translations or adaptations of Norman French originals. The translation of the Welsh Bible (1588) laid the foundation for modern Welsh prose. The novels of Daniel Owen (1836–1895) are not much inferior to the work of Dickens. The short stories of Kate Roberts (1891–) and the novels of T. Rowland Hughes (1903–1949) are real works of genius.

More is printed in Welsh—in books, papers, and magazines—than in all the other Celtic languages together. Methodism has saved the Welsh language, but has killed much of the old folk culture of Wales, which in many instances goes back to Megalithic times.

Cornish Literature.—Though the preserved remains of nonreligious literature in Cornish are very scanty, there must have existed a large amount of Old Celtic legends in Cornwall during the Middle Ages. Arthur's treacherous nephew Modret bears a purely Cornish name; in the story of Arthur, Cornwall plays a very important part. Similarly the topography of the *Tristan* saga in the sources of the Anglo-Norman writer Bérout is predominantly Cornish, as shown by J. Loth (*Revue celtique*, 33:258–310 [1912]). The form of many Celtic names in the French epics shows that they must ascend to written Cornish and Welsh sources. There cannot be

much doubt that the world owes to Cornwall and Wales the *Matter of Britain*. Owing to the Norman Conquest, Cornwall (where the French encountered a Celtic population dominated by an English aristocracy) grew to be a trilingual country, so that it is probably to Cornwall and not to Brittany that we owe the transmission of the Celtic legends to the Continent.

Unfortunately the only nonreligious literary remains are a few Cornish conversations, some songs, proverbs and epigrams, and a folk tale, the story of John of Chy-an-Hur (*The Ram's House*), the plot of which is well known in Ireland and elsewhere. Apart from a long poem on the Passion, the religious literature consists chiefly of mystery plays of learned origin and imitated from English sources. Furthermore, there are fragments of translations, such as chapters of Scripture, the Lord's Prayer, and the Commandments. When the Reformation began, neither the Prayer Book nor the Scriptures had been translated into Cornish; and when the Methodist movement came, it was too late. Some enthusiasts lately have attempted a kind of revival of Cornish, which even has produced some fine lyrics and a mystery play.

Breton Literature.—The earliest piece of connected Breton has been preserved in a manuscript of the 14th century. It seems to be a fragment of a love song, similar to the contemporary French chansonette. No other examples of the rich Breton poetry of the Middle Ages have been preserved. The earliest Breton printed work, a Breton-Latin-French dictionary, the *Catholicon* by Jean Lagadeuc, was published in 1499. French seems to have been the language of the aristocracy and the medium of culture; hence the oldest texts are either translated or imitated from French. The early literature is almost exclusively religious, such as *The Hours in Latin and in Breton* (1486) and *The Mirror of Death* (1519).

The bulk of Breton literature before the 19th century consists of mysteries and miracle plays. Brittany is the only Celtic land where the theater, though not of native growth and only introduced from France, has met with an immense popular favor. Upwards of 150 Breton mystery plays are known to exist. The oldest, the *Life of St. Nonn*, belongs to the end of the 15th century and is modeled on the Latin life. The mysteries were adaptations mostly from French or Latin and are full of French words. From the 18th century we also find plays dealing with romances of chivalry, like the *Tragedy of the Four Sons of Aymon* (of which no less than 15,000 copies were sold), *Huon de Bordeaux*, and *Robert the Devil*. Their subject matter is likewise taken from French sources and their chief interest lies in the fact that they are the last creations of the medieval theater.

Only the 19th century brought an original Breton literature. The movement was led by Jean François Le Gonidec (1775–1838), the author of the first Breton translation of the Bible (1868) and of the first scientific Breton grammar, *Grammaire cello-bretonne* (1807), and an excellent dictionary (1821). It caused ardent patriots to endeavor to create a national literature. At about the same time, the attention of the whole world of letters was directed to Brittany, when Hersart de la Villemarqué (1815–1895) published his famous collection *Barsas Breiz* (*The Poetry of Brittany*) in 1839. The publication of this work gave rise to a protracted and heated discussion, which is almost as famous as that caused by Mac-

pherson's Ossian forgeries. Today we know that he had transformed the material which he had collected, eliminating anything which he believed to be crude and gross. He transferred modern poems to medieval times, rearranged others, and composed some himself. But at least he had a fluent command of Breton and his book is not only a great and really beautiful work of art, but also in linguistic respect much superior to that of Macpherson. His poems gave, just as in Scotland, the signal for a serious study of the popular Breton ballads, legends, and folk tales which form the real literature of Brittany. The most famous collections we owe to F. M. Luzel (1821-1895) and Anatole Le Braz (1859-1926).

It is usual to divide the popular Breton poetry into *gwerziou* and *soniou*. The *gwerziou* (complaints) are short ballads or complaints, or village tales in verse of a highly dramatic quality and usually of tragic interest. The *soniou* (songs) consist of love songs, satires, carols, sailors' songs, and sometimes show traces of French influence. The Breton folk tales and legends are extremely valuable from the folkloristic point of view and show some very archaic traits. In 1839 (when Villemarqué published his *Barsas Breiz*) there appeared the first book of Prosper Proux (1811-1873), *Kanaouennou eur C'hernewad* (*Poems of a Man from Cornouailles*), one of the few original Breton poets of the 19th century. Another great poet of that time was Auguste Brizeux (1803-1858), the author of *Telen Arvor* (*The Harp of Brittany*).

A new important literary movement started in the 20th century. It was inaugurated by the work of linguistic specialists, like Émile Ernault (1825-1938), François Vallée (Abhervé) and René le Roux (Meven Mordiern). In 1918 there came into being a small circle of intellectual writers, whose work found expression in the pages of the journal *Gwalarn* (*The Northwest*), which appeared from 1925 to 1944, to be continued from 1946 by *Al Liamm* (*The Bond*). Already in 1921 a small volume of poetry had been published, written in the Vannes dialect, by Jean Pierre Calloc'h (d. 1917) under the title *War an Daoulén* (*A Genoux*), published with a French translation. His poetry is mystic and Catholic and completely free from the platitudes of his contemporaries. Thence a new poetry came into existence, worthy of the best which other countries have produced. Among the younger poets may be mentioned: Xavier de Langlais, Maodez Glanndour, Roparz Hémon, and many others. Some of the finest examples of Celtic nature poetry are found among the poems of Roparz Er Mason: *Chal ha Dichal* (*Flood and Ebb-tide*), published with a French version in 1943.

Quite a new feature in Breton literature is the short stories of Jakez Riou, Roparz Hémon, and Kenan Kongar. The novel *Itron Varia Garmes* (*Our Lady of Carmes*) by Youenn Drezen has been translated into French under the title *Notre-Dame Bigoudenne*.

A modern theater is being created by the work of Tangi Malmanche, Xavier de Langlais, and Roparz Hémon. Some of their work almost equals that of the Anglo-Irish poets, such as Yeats and Synge. The patriotic work of all those young idealists is the more to be admired, because they have no help whatever from any official circles. The French government is very hostile to all their efforts and tolerates the Breton language neither in public schools nor in public insti-

tutions, fearing a resurgence of the old separatist movement.

JULIUS POKORNY,
Former Professor of Celtic, University of Berlin;
now in Zurich, Switzerland.

CELTIC PEOPLES. The term Celts denotes groups of peoples who spoke or still speak a Celtic language. The ancient Greek writers used the name Κελτοί (Latin *Celtae*) as a general racial designation of those peoples. It was probably generalized from the name of the small groups of Celts with whom the Greeks first came in contact, the stem *Celt-* occurring frequently in ancient Spain. At the meaning we can only guess, for there are various roots of the form *kcl-* (such as to raise, to beat). From another root *gal-*, probably related to Old Irish *gal* (courage), are derived the names *Galli*

(Gauls), a later rival to the old name of Celts, and Γαλάται (Galatians), originally the name of the Celtic invaders of Macedonia and Greece.

Race.—Since language is the chief criterion by which we can distinguish the Celts from other European peoples, there can be, of course, no question of a "Celtic race." Yet the problem of race must not be discarded altogether. Greek and Latin writers, when speaking of the Celts, described them as a tall, fair-haired, blue-eyed, white-skinned people. It has been demonstrated that it was only these Celts who attracted the attention of the classical writers (accustomed to an almost uniformly dark-haired and dark-eyed population), and that they naturally would seize upon the points of distinction and would regard them as generally typical. We also know that some of the Gauls were less fair than the rest. But on the other hand, the ancients did not distinguish between Celts and Teutons before Caesar (100-44 B.C.) and the earliest Celtic graves in the basin of the Marne, in Lorraine and Franche Comté, as well as the Early Iron Age graves in England, contain almost without exception tall, dolichocephalic skeletons, which point clearly to a Nordic origin. In the earliest Irish sagas most of the heroes and princes are described as fair-haired and blue-eyed. All this shows beyond doubt that the upper classes must have belonged to the Nordic race. Since we know that before the Nordic invasion the greater part of the Celtic home in the south of Germany and in Switzerland had been populated chiefly by Alpine and Dinaric races, we should expect a far greater percentage of Alpine roundheads in the British Isles, if these had formed a considerable part of the Celtic warrior caste. The predominant Nordic character of the invading Celts in the British Isles, however, may also be due to the fact that the starting point of those invasions comprised the regions on the lower Rhine, where the Nordic element was far stronger than farther south.

Home.—The ancestral home of the Celts is probably to be sought in southwest Germany (with the Swiss plateau), and in eastern France. Archaeologically it is manifest in the Western Bronze Age tumulus culture (1500-1200 B.C.), formed on a substratum of Neolithic and ultimately Mesolithic stocks by the addition of roundheaded Dinaric (bell-beaker) folk from the southwest (Spain), and finally Indo-Europeanized by the longheaded Nordic battle-ax warriors (corded-ware people) from central Germany (c. 2700 B.C.).

Urnfield Invasion.—These early Celts were overrun in the 12th century B.C. by the Urnfield people who ultimately came from the middle Danube. (Urnfield refers to the custom of cremation burial in urns.) But eventually the older population reasserted itself and finally absorbed its conquerors. The language of this Urnfield people may perhaps be called Central-Indo-European or Veneto-Illyrian. The Urnfield culture was genealogically connected with the Lusatian (Lausitz) culture of the northern Veneti, but had absorbed on the middle Danube and elsewhere northern Illyrian elements. Its language is merely to be inferred from place and river names, which extend from Hungary to as far west as Spain and the British Isles. These names are clearly Indo-European, but they are neither Celtic nor Italic nor Germanic. They seem, however, to form a kind of link between

Celtic and Baltic. Many western European river names are strangely identical with Baltic (Lithuanian and Lettish) river names. Their geographical distribution seems to show that the spread of the Urnfield culture in the Late Bronze Age was due not merely to cultural influences, but also to actual conquest. The Aquitanian tribal name *Camponi* corresponds to the Pannonian place name *Campona* (compare Lithuanian *kam̃pas*, corner); the Greek name of the north Spanish plain Κοπλάνιον stands for **komplānion* (compare Latin *plānus*; Old Irish *lán*, full); in Britain, the old name of Richborough: *Rut-upiæ* contains *upiā* (river), also found in Lithuanian *upė*, from **upiā* (river).

Early Migration.—Some of the Urnfield invaders spread farther west beyond the Celtic ancestral home, probably carrying early Celtic elements along with them, just as 1,500 years later Iranian Alani were wandering with Teutonic Vandals from Hungary to Portugal. Those first Indo-European conquerors reached, in the 10th century B.C., southwestern France, northern Spain (over the eastern Pyrenees), and (from the lower Rhine) the British Isles. The first great phase of the Early Iron Age in central Europe, known as the Western Hallstatt culture (originating after the absorption of the Urnfield elements by the Proto-Celtic tumulus culture in the 10th century B.C.), can safely be called Celtic. Under the pressure of the Teutons, who, from the 8th century B.C. onward, penetrated westward and drove the Celts step by step nearer to the Rhine, the Hallstatt Celts on the lower Rhine followed the same route as their predecessors, the Urnfield people.

Northern Branch.—The northern branch crossed the English Channel and brought during the Late Hallstatt period (probably in the 7th century B.C.) purely Celtic invaders to Britain (British Iron Age A).

Southern Branch.—The southern branch moved toward Spain, crossing the western Pyrenees. This late Hallstatt invasion of Spain led to a Celtic conquest of all the northwest of the peninsula, including the northeast part of the central plateau, the country of the Celtiberians in a strict sense. The term Celtiberians denotes Celts who, from the 3d century B.C., fell more and more under the influence of the Iberians. Their numerous inscriptions, though written with Iberic letters, are almost pure Celtic of the archaic *Qu*-type and represent the earliest traces of the Goidelic (Gaelic) dialect, as found in Ireland and Scotland—in fact the only certain examples of Goidelic on the Continent.

These Spanish Celts were the first Celts who became known to the Greeks. The earliest reference to them is found in Rufus Festus Avienus' *Ora Maritima* (c.385 A.D.), which is drawn from a Greek original, composed probably in the 6th century B.C. The well-known passage in Herodotus (book ii: 33, 3) in which he mentions the Celts as the neighbors of the Portuguese Cynesians, was taken from Hecataeus of Miletus (c.500 B.C.). Therefore history itself shows that the Celtic invasion of Spain must have occurred about 600 B.C. The archaic character of the Celtic occupation of the Iberian Peninsula is also shown by the place names with *-briga* (fortress, the Celtic equivalent of German *Burg*), which

The asterisk (*) indicates that this particular word form is conjectured and reconstructed.

are here more frequent than anywhere else and indicate warlike settlements in a hostile country. Names with *-magus* (plain) and *-ialum* (clearing), which are very frequent in Gaul, do not occur on Iberian soil.

Later Migration.—The Western Hallstatt period (1000–500 B.C.) was followed by the La Tène period (500–1 B.C.), the Late Iron Age in Celtic lands. It was a mere cultural development, owing to the spread of classical ideas and fashions from Italy and southern France. The growing wealth in southwest Germany and eastern France led to a constant increase of the population and subsequently, about 425 B.C., there began the great expansion of the Celts all over middle, western, and eastern Europe. All these La Tène Celts belonged to the so-called *P*-group which changed Early Celtic *qu* to *p* (Goidelic *equos*, horse; Gaulish *epos*).

Western Branch.—Spain was probably invaded by *P*-Celts during the period of La Tène II (250–100 B.C.), though this fact is not universally acknowledged. The whole of France now became Celticized. The Hallstatt invasion into Britain was followed in the 3d century B.C. by a La Tène invasion (British Iron Age B). With the landing of Belgic tribes in 75 and 50 B.C., the Celticization of Britain was complete.

According to Caesar, the ancient Belgae were mostly of Teutonic origin. Their name is to be connected with Old Irish *bolgaid* (swells) and Old High German *belgan* (to swell). Linguistically, however, they were completely Celticized in historical times. According to Pedro Bosch-Gimpera (see *Bibliography*) they not only invaded Britain in the 1st century B.C., but also had wandered in the 6th century B.C. through western France into Spain—a theory which, however, remains to be proved.

Ireland.—The Celtic invasions of Ireland present a very difficult problem. All we can say is that there must be some connection between the Goidelic settlements of Spain and those of Ireland. Either both came from the same ancestral home on the lower Rhine (in which case we must assume an invasion by way of Britain, not far removed in date from the Spanish Hallstatt invasion) or, perhaps, the Goidels reached Ireland directly from Spain or by way of Brittany along the Atlantic sea route, by which the megalith builders had come from Spain to Ireland about 2500 B.C. That we know of no Goidelic traces in Britain going back to the 7th century B.C. is not surprising if we consider that Brythonic and Goidelic were still very close to one another even in St. Patrick's time (389?–?461 A.D.). At any rate, the last important Celtic infiltration into Ireland about the middle of the 2d century A.D. must have reached the north of the island through Britain. It brought late La Tène elements from Yorkshire, ultimately going back to the Marne. This Brythonic element in Irish, however, was soon absorbed and became completely assimilated to the older Goidelic population.

Southern Branch.—Other La Tène Celts from 400 B.C. onward conquered the whole of Upper Italy, sacking Rome about 390, and penetrating as far as Campania and Apulia. About the same time these warlike peoples conquered the remainder of middle and southern Germany (hitherto in possession of the eastern Urnfield peoples), the Alpine forelands along the Danube, Bohemia, Moravia, Silesia, and Hungary. As early as 350 B.C. they appeared on the shores of the

Adriatic Sea, sending envoys in 335 to the camp of Alexander. Shortly afterward they conquered Illyria proper and Thrace. In 279 they invaded Greece and looted Delphi. Passing the Hellespont in 278–277, they founded the Celtic empire of Galatia. It was to the descendants of those Celts in Asia Minor that St. Paul addressed his Epistle to the Galatians. Others went along the coast of the Black Sea as far as the Sea of Azov, the extreme limit of their eastern advance.

Conclusion.—In the modern sense of the word, there never was a Celtic empire. The Celts neither formed a political unity nor possessed a strongly centralized government. Hence, almost everywhere they fell an easy prey to the Teutons and the Romans. The genius of the Celtic peoples has been more remarkable for its creative imagination and a certain love for the irrational than for its abilities for organization. Their poetic and musical inclination was so deeply rooted that they never have been remarkable in architecture, sculpture, representative painting, or in any manifestations in the abstract. The large admixture of the pre-Celtic Mediterranean element in Great Britain and Ireland, where they found their last refuge from stronger races, has still strengthened these characteristic traits. Particularly in Ireland the Megalithic civilization of the Neolithic Age may be said to be still a living force. But the descriptions of the continental Celts which we possess from Greek and Latin sources still hold good. They all emphasize the Celtic love of fighting, daring, and adventure, their imagination, loquacity, and religiosity. Though they have not succeeded in leaving permanent political traces, their influence on Western civilization is by no means to be despised. It goes deeper than many of us are likely to believe. CELTIC RENAISSANCE. See **IRISH LITERARY REVIVAL.**

CELTIS, tsél'tis, or **CELTES**, tsél'tés, sél'téz, **Conradus**, (original name KONRAD PICKEL); German humanist and poet: b. Wipfeld, near Schweinfurt, Germany, Feb. 1, 1459; d. Vienna, Austria, Feb. 4, 1508.

He studied under Agricola in Heidelberg, then taught in Erfurt, Rostock, and Leipzig. He was professor of rhetoric and poetry at Ingolstadt (1492-1497), and at Vienna (1497-1508). He promoted the study of Latin and Greek and systematized the methods of teaching them; discovered Peutinger's Table (q.v.), and the Latin plays of Roswitha (q.v.). He was librarian to Maximilian I, and the first poet laureate of Germany.

His most important work was *Ars Versificandi et Carminum* (1486).

CELTIS, sĕl'tis, a genus of trees of the natural order Ulmaceae, closely related to the elm. *C. australis* is the nettle-tree (q.v.).

CEMENT. In modern parlance, the term "cement" refers to any material that is used as a bonding agent for causing diverse materials to adhere. Many of these agents are described elsewhere under such designations as asphalt, glue, mucilage, plastics, putty, and solder (qq.v.). The application of hydraulic cements in the construction and road-building industries has become so extensive, however, that the unmodified term "cement" now refers almost exclusively to those products.

A hydraulic cement is a material that forms a bond, as between blocks of stone, by virtue of a chemical reaction with water, the product of such reaction being a hard stonelike substance which from the time of its formation is resistant to disintegration in water. Many combinations of the mineral oxides would qualify as hydraulic cements but cannot compete in ordinary construction because of their cost. This restriction limits the field to specific combinations consisting for the most part of silicates and aluminates of lime. Three classes have been developed commercially: natural cements (including hydraulic limes), aluminous cements, and portland cements. Each of these classes has been modified in various ways, either by limiting compositions, by blending with other materials, or by the introduction of admixtures. Various names are given to these products, some of which disclose their nature and others of which are copyrighted trade names.

Natural Cement.—When a pure limestone (calcium carbonate) is calcined, the resulting quicklime (calcium oxide) slakes rapidly in water with the evolution of considerable heat, and the product (calcium hydroxide) forms a putty that does not set under water. Its use as a plaster or a mortar (the bonding agent mixed with water and sand) is dependent on interaction with the carbon dioxide in the air, resulting in the formation of a moderately hard bond of calcium carbonate. The calcined product of such a limestone is called fat or high-calcium lime. But when the limestone contains up to 25 per cent of argillaceous material, such as clay or shale, the calcined product reacts slowly with water; there is no rapid evolution of heat; and a hard product is formed that does not disintegrate under water. The calcined product of such a limestone is called hydraulic lime or natural cement. The composition varies from a relatively low (10 to 20 per cent) silica and alumina content to a relatively high one (20 to 35 per cent). There may be present also 10 to 25 per cent of magnesia. The higher grades, giving the higher cementing values, usually carry the designation "natural cement."

These products are made by calcining at temperatures below sintering, lumps of naturally occurring limestones that contain the argillaceous material indicated.

The amount of hydraulic lime and natural cement produced in the United States in 1952 was about 3 million barrels. (The barrel is the standard unit of weight for hydraulic cements in the United States. A barrel of cement is 371 pounds, or four bags of 94 pounds each.) Much of this was used either as an admixture with portland cement or as an ingredient of masonry cements. The term masonry cement applies however, not to any particular class of cement but to the use for which the material is made, that is, as a mortar to bond brick or stone.

Aluminous Cement.—Aluminous or high alumina cements are made by heating a mixture of limestone and bauxite until molten. The finely ground product, consisting principally of aluminates of lime, has the property of reacting rapidly with water to form a hard mass that is resistant to water and sulphate solutions. Its rapid rate of hardening, faster than ordinary portland cement, makes it suitable in the placing of highway and street intersections where traffic diversion must be as brief as possible. Its resistance to salt action has led to its use in some severe exposures. A further application of importance is in the insulation of furnaces where high temperatures are encountered. In the United States, aluminous cement is made by one company under the trade name of "Lunnite." In France and England it is known as "Ciment Fondu."

PORTLAND CEMENT

The name "portland cement" was given in 1824 by Joseph Aspdin, a bricklayer of Leeds, England, to a hydraulic lime that he patented, because when set with water and sand it resembled a natural limestone quarried on the Isle of Portland in England. At about the same period it was discovered that the pulverized nodules of material, called grappiers, which occasionally became sintered on burning hydraulic lime, and which were formerly discarded, produced a cement of much higher quality than that obtained from the unsintered material. This fact was firmly established by I. C. Johnson in 1845, and the name "portland cement" has since then been applied solely to the cement made from the sintered material. This period marks the real beginning of the portland cement industry.

During the past hundred odd years, the product has won universal acceptance and the demands of the engineers have imposed constantly rising standards of quality. Extensive researches under way in nearly every country have produced precise information on the relationship between the nature of the cement and its performance in service. The cement manufacturing plant has evolved from a roadside kiln to a vast assemblage of machinery where mountains are converted into the bonding material of concrete.

The first portland cement to be made in the United States was produced by David Saylor at Coplay, Pa., in 1871, in vertical kilns somewhat similar to those used for burning lime. The increasing demand for both quantity and quality led to the introduction in 1899 of the rotary kiln. This kiln had been invented by Frederick Ransome in England in 1885, but had not been enthusiastically received there. From the turn of the century, the production of natural cement in

Above: The first step in the manufacture of cement is to blast thousands of tons of stone from the face of a limestone quarry. Sometimes 400,000 tons of rock are dislodged in a single blast.

CEMENT

Below: After the blast, the broken rock is loaded into trucks and taken to the mill for the first crushing operation.

Right: Limestone, gypsum, clinkers and other materials are kept in large storage bins, filled or emptied by traveling cranes.

Portland Cement Association

Above: The climax of the manufacturing of cement takes place in the rotary cement kiln, a steel cylinder sometimes 12 feet or more in diameter. If placed on end, an average-sized kiln would equal a 40-story building in height.

Left: The worker is looking into one end of the rotary cement kiln, where the raw materials are subjected to heat of about 2,700° F. The heat transforms the materials into marble-sized balls or clinkers.

Bottom left: After the clinkers have been ground to a fine powder in two operations, an automatic packing machine is used to put the finished product into 94-pound bags.

Below: Finished cement is kept in large storage silos.

Portland Cement Association

the United States has declined from its peak of nearly 10 million barrels and the production of portland cement has assumed gigantic proportions, rising from 8 million barrels in 1900 to 264 million barrels in 1953.

In addition to the standard types of portland cement, described below, many modifications have been manufactured. Thus, white portland cement is made for special architectural uses and differs from regular portland cement chiefly in having a very low content of ferric oxide. Oil well cement is made for sealing oil wells and so must be slow-setting and able to resist high temperatures and pressures. The substitution of some iron oxide for clay has been found to improve the resistance to sulphate waters, and such cements are manufactured under the names of Ferrari and iron-ore cement. Most important of the modified portland cements are the slag and pozzolanic cements which are made by inter-

Production of portland cement in the United States, 1895 through 1953.

grinding from 15 to 85 per cent of granulated blast furnace slag or pozzolanic material with the portland cement clinker. In some cases, no portland cement clinker at all is used, but only slag and lime or slag and anhydrite.

Pozzolana was named for a volcanic tuff from the neighborhood of Vesuvius in Italy. The Romans found it valuable in improving the quality of mortars used in their building operations. The name is now given to a variety of naturally occurring materials such as volcanic ash, trass, Santorin earth, and pumicite; and artificially prepared materials such as burned clays, or diatomaceous earth, that have the capacity to combine in water with lime to form a calcium silicate. The use of slag and pozzolana, though common in Europe, has not made appreciable headway in the United States.

Manufacture.—The raw materials of portland cement consist principally of limestone or some other lime-containing material such as

marl, chalk, or shells; and clay or shale or some other argillaceous material such as ashes or slag. The severity of the chemical restrictions is such that calcium oxide, silica, alumina, and ferric oxide must be present within narrowly defined limits, and other constituents, such as magnesia and alkalies, must not exceed specified limits. These restrictions necessitate at times the introduction of other types of rock besides those immediately available, such as a high-calcium limestone, sandstone, or iron ore. On other locations it is sometimes necessary that the available material be beneficiated, as by flotation, to remove excessive amounts of silica, iron oxide, carbon, magnesia, alumina, or alkalies.

All raw materials must be ground to an impalpable powder and intimately mixed before burning. In a modern cement plant this is a prodigious task, for the rock has first to be blasted out of the mountain, then fed into a giant crusher that takes blocks as large as a grand piano, then broken and hammered and pulverized to the fineness of flour. But this is not all, for the clay or shale and other materials must be thoroughly mixed with the lime rock. Blending of the rock may begin in the quarry and continue as the raw materials flow into each crusher or mill. In the *dry process*, all grinding and blending operations are done with dry materials and the final mixing is accomplished chiefly in the grinding mills. In the *wet process*, the final grinding and blending are brought about in a water slurry, and the mixing is accomplished both in the grinding mills and by stirring in large vats. In both processes, rigid control of the composition of the final kiln feed is attained through chemical analyses made on the raw materials at various stages of the operation, and the subsequent measured blending of mixtures to attain the required composition.

The water is partially removed from slurries by various processes: by gravity settling of the solids in a thickener; by filtration of the water through canvas-covered rotating drums the interiors of which are under reduced pressure; and by evaporation of the water in various kinds of heat exchangers. Often, however, the slurry is fed directly into the kilns and the water is removed by evaporation aided by chains or baffle plates inserted in the back ends of the kilns.

The rotary kiln has completely replaced the vertical or shaft kiln in the United States; the present size varies from 60 to 500 feet in length and from 6 to 15 feet in diameter; the capacity, from 200 to 4,000 barrels a day. The kiln is set at an inclination of about one half inch per foot and rotated at a speed of between 30 and 90 revolutions per hour, causing the load to work its way downward toward the discharge end. There heat is introduced, usually by a blast of ignited powdered coal and air, or less commonly with fuel oil or gas. During passage of the mixture down the length of the kiln, several reactions take place at various temperature levels. These may be classified as: (1) evaporation of water; (2) decarbonation of limestone and magnesite; (3) sintering of part of the charge; and (4) interaction to form silicates or aluminates.

The liquid that forms during the burning process causes the charge to agglomerate into nodules of various sizes, usually one quarter to one inch in diameter, and characteristically black, glistening and hard. This material is known as portland cement clinker. The charge drops from the

CEMENT

Typical flow sheet of wet process portland cement plant.

end of the kiln into some form of cooler and is then ground, usually with 4 to 5 per cent of gypsum (hydrous calcium sulphate), to a powder so fine that most of it will pass through a sieve that will retain water; more specifically, the fineness is specified by a minimum average surface area of 1,600 to 1,800 square centimeters per gram, depending on the type of cement being made. The purpose of the gypsum is to cause a grout of the cement with water and aggregate (as fresh concrete mix) to remain fluid and workable over a period of several hours. Without the addition of gypsum the grout might set before it had been properly placed in the forms.

In Europe the shaft or vertical kiln is still extensively used because it can be operated with greater fuel economy than the rotary kiln. It is claimed that new improvements have been made that give the shaft kiln a competitive status with the rotary kiln with respect to uniformity and quality of clinker produced. A sinter-grate kiln also is in use in which the nodulized charge containing coal or coke is burned on a travelling grate, and ignition is produced by a downblast of burning oil, and continued by drawing hot air down through the moving charge by means of an exhaust fan.

Composition.—Research on the minerals from which portland cement is made has revealed the nature of the compounds that are formed by subjecting any mixture of cement raw materials to clinkering temperatures. With that information it has been possible to design mixtures for the production of cements with various desired properties. Thus five types of portland cement are now included in the standard specifications of the American Society for Testing Materials and the Federal Specifications Board. These are:

Type I: for use in general concrete construc-

tion where the special properties specified for Types II, III, IV, and V are not required.

Type II: for use in general concrete construction exposed to moderate sulphate action or where moderate heat of hydration is required.

Type III: for use where high early strength is required.

Type IV: for use where low heat of hydration is required.

Type V: for use where high sulphate resistance is required.

Each of the above types of portland cement may be obtained either with or without the presence of an agent by which air will be entrained in the paste when the cement is mixed with water and aggregate. The purpose of the entrained air is to improve the durability of the concrete, especially under exposure where cycles of freezing and thawing are to be encountered.

The standard specifications are designed to assure the user of the cement that certain standards of quality will be attained when the cement is used in accordance with recognized good practice. These qualities are largely determined by the presence in the cement of definite amounts of certain compounds which impart the dominant characteristics to the concrete. The table on the following page indicates typical principal oxide compositions of a number of cements.

The principal compounds of portland cement, formed by the reactions in the kiln, are the following:

Tricalcium silicate ($3\text{CaO} \cdot \text{SiO}_2$), which is chiefly responsible for initial set and early strength of the cement-water paste.

Dicalcium silicate ($2\text{CaO} \cdot \text{SiO}_2$), which hardens slowly but contributes notably to strength at ages over one month.

Tricalcium aluminate ($3\text{CaO} \cdot \text{Al}_2\text{O}_3$), which

	Silica SiO ₂	Alumina Al ₂ O ₃	Ferric Oxide Fe ₂ O ₃	Lime CaO	Magnesia MgO	Insoluble
Portland Type I	21.3	6.0	2.7	63.2	2.9	0.2
Portland Type II	22.3	4.7	4.3	63.1	2.5	0.1
Portland Type III	20.4	5.9	3.1	64.3	2.0	0.2
Portland Type IV	24.3	4.3	4.1	62.2	1.8	0.2
Portland Type V	25.0	3.4	2.8	64.1	1.9	0.2
Portland white cement	25.5	5.9	0.6	65.0	1.1	..
Natural cement	27.8	5.5	4.3	35.6	21.2	..
Aluminous cement	5.3	39.8	14.6	33.5	1.3	4.8
Pozzolan cement	26.0	6.9	3.6	52.3	4.2	9.4

liberates a large amount of heat during the first few days of hardening, and is rapidly attacked by sulphate solutions.

The iron-containing phase (a solid solution approaching the composition $4\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot \text{Fe}_2\text{O}_3$), which is valuable as a flux in manufacture.

Magnesia (MgO) which, if present in excessive amount, may cause expansion of structures exposed to moisture after a number of years.

Calcium sulphate (CaSO_4), which is interground with the clinker to control the rate of setting of the cement-water paste.

Free lime (CaO), which results from incomplete reaction in the kiln, and if present in amounts over 2 or 3 per cent may cause unsoundness and expansion in the cement paste.

From the above account it will be seen that the amounts of the several compounds present in a cement will determine many of the properties of a concrete made therefrom. The following table gives typical principal compound compositions of the five standard types of portland cement:

	$3\text{CaO} \cdot \text{SiO}_2$	$2\text{CaO} \cdot \text{SiO}_2$	$3\text{CaO} \cdot \text{Al}_2\text{O}_3$	$4\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot \text{Fe}_2\text{O}_3$	CaSO_4	MgO	Free CaO
Type I	45	27	11	8	3.1	2.9	0.5
Type II	44	31	5	13	2.8	2.5	0.4
Type III	53	19	11		4.0	2.0	0.7
Type IV	28	49	4	12	3.2	1.8	0.2
Type V	38	43	4	9	2.7	1.9	0.5

Utilization.—Portland cement depends for its usefulness on a series of reactions between the compounds of which it is composed and water. Most important of those reactions is the hydration of the calcium silicates to form a colloidal gel of calcium silicate hydrate that solidifies to a hard mass. This material forms a continuous phase that surrounds and encloses each piece of aggregate in a concrete grout, and bonds the whole into a rocklike structure. The behavior of the material will be determined by many factors, such as composition of the cement, fineness of the cement, the water-cement ratio of the paste, the grading and nature of the aggregate, and the time, temperature, and manner of curing. Also, as previously stated, the presence of entrained air in the paste will greatly affect the durability of the structure in some exposures. Extensive research is under way in many countries on the problems bearing upon the reactions of the cement compounds with water and the character of the hydration products. The methods of study include X-ray powder diffraction, crystal structure, electron microscopy and diffraction, phase equilibria, differential thermal analysis, spectroscopy, heats of reaction and others. By these means information is accumulating on the chemical nature of the several hydration products, the arrangement of the atoms in the crystals, and the morphology of the gel hydrates. Knowledge of the composition and structure of the materials

leads to an understanding of why they behave as they do and hence to a control of their properties. It is by means of basic research of this character that the cement industry has advanced to supply the construction demands of a rapidly growing society. For further information on the design, fabrication, curing, and durability of concrete structures, see CONCRETE.

CENABUM is an ancient name for Orleans, France (q.v.).

CENCI, chèn/chè, Beatrice, Italian noblewoman, tragic figure of the late Renaissance: b. Rome, Feb. 6, 1577; d. there, Sept. 11, 1599. One of the 12 children of Francesco Cenci (1549-1598) by his first wife, she was born in the Palazzo Cenci, Rome. Francesco, a man of violent temper and debauched life, hated and feared by his family, in 1595 imprisoned his second wife Lucrezia with Beatrice in a lonely castle of the Colonna family called La Petrella, on the road to Naples. During occasional visits to La Petrella he mistreated the women. Apparently he was unaware that Beatrice and Olimpio Calvetti, the castellan, had fallen in love; however he had Olimpio discharged from his command. Finally Beatrice, her brothers Giacomo and Bernardo, and their stepmother plotted the death of the unnatural father. Olimpio and a hired assassin murdered Francesco in his bed on Sept. 9, 1598. Early the next year the entire Cenci family was arrested. Lucrezia and the two sons confessed,

as did Beatrice, finally, under torture. Pope Clement VIII refusing a pardon, the women were publicly beheaded, Giacomo was put to death after long torture, Bernardo alone being spared on account of his youth, and released after a year's imprisonment. The family estates were confiscated.

A portrait by Guido Reni in the Palazzo Barberini, Rome, is said to represent Beatrice. Shelley's tragedy, *The Cenci* (q.v.), is based on a version of the episode, which has been the theme of many novels, notably F. D. Guerrazzi's *Beatrice Cenci* (Milan 1872). The best historical account is that by Corrado Ricci, *Beatrice Cenci* (Milan 1923; Eng. tr. London and New York 1925).

CENCI, The. Shelley's poetic tragedy *The Cenci* was his one attempt to write "for the multitude" and for the stage. Though following the model of Elizabethan tragedy, and containing echoes from Shakespeare—mainly from *King Lear*, *Macbeth*, and *Othello*—it is yet a work of individual genius. While it may be uncritical to assert that *The Cenci* is "the greatest English tragedy since Shakespeare," it is the writer's opinion that no tragic poet since John Webster (1580?-1625) had equalled this play in somber power.

The plot is founded on an old manuscript account of the crime, trial, and execution of Beatrice, a daughter of the great Roman family of the Cenci, at the close of the 16th century. This particular account, one of many such that appeared within the century following the event, is utterly misleading in its picture of Cenci as an unnatural monster and of his daughter as an angel of light; but Shelley accepted it as authentic, and followed it closely, except that he added the banquet scene in the first act. His interest was increased by the supposed portrait of Beatrice, reputedly by Guido Reni.

The play was published in London in 1819. Though received with comparative favor by the public, it was criticized on account of the nature of its subject. Shelley, who was an almost infallible critic of his own poetry, said, "It is a work of art; not colored by my feelings nor obscured by my metaphysics." And, indeed, *The Cenci*, intrinsically great, is no less than astonishing as the production of the poet of *Prometheus Unbound*. Except for the evidence of this play, no one could have credited Shelley with so much knowledge of human character and such power to represent it.

Owing to the difficulty of presenting the incidents of the story on the stage, the action of *The Cenci* is weak. The fifth act, however, is not only perhaps the finest thing that Shelley ever wrote, but certainly compares favorably in all essentials of tragedy with anything outside of Shakespeare. The characterization is on the whole firm and convincing; though Orsino, whose crafty wickedness is contrasted with the utter insolence of Cenci, seems hardly consistent. The vacillating Giacomo and the irresolute Lucrezia throw into high relief the unwavering will of Beatrice, who grows in nobility until at the close she fills the action with the splendor of her purity and strength, a tragic heroine claiming kinship with the greatest of her kind—with Antigone, Electra, Juliet, Constance, and Webster's Duchess of Malfi. The diction is simple and concrete; the style, highly dramatic and appropriate. Except for the description of the chasm

in the third act, not a passage, scarcely even a line, but contributes directly to the action or characterization. The effect of the play is that of unrelieved gloom. As George E. Woodberry puts it, "In it culminates that fascination of horror in Shelley which was as characteristic as his worship of beauty and love, though it is less omnipresent in his poetry."

MARION TUCKER.

CENERENTOLA, La, opera in two acts, based on the story of Cinderella, with music by Gioacchino Rossini and a libretto by Jacopo Ferretti. Among Rossini's operatic works, *La Cenerentola* is generally placed just below *Il Barbiere di Siviglia*, though it has not held so enduring a position on the opera stage.

Poorly received in Rome at the time of its first performance on Jan. 25, 1817—barely one month after Rossini and Ferretti had begun their collaboration on the work—*La Cenerentola* won great popularity by the end of the opera season that year. This was largely because the main role's great difficulties were an irresistible challenge to the singers of the time. However, the decline of the *bel canto* tradition, particularly in the mezzo range in which the title role is written, resulted in the gradual disappearance of *La Cenerentola* from the repertoires of opera companies. There are no records of professional performances between 1860 and 1934.

In the latter year the opera was revived with the Spanish mezzo, Conchita Supervia, singing the lead at a performance in London, and the New York City Opera Company produced the work on March 26, 1953, with notable success.

CENIS, Mont, mōns-nē' (Ital. *MONTE CENISIO*, mōn-tā chā-nē'zyō), a peak of the Graian Alps between Savoy in France and Piedmont in Italy, on the frontier between the two countries. It is composed mainly of strata of schist, limestone, and gypsum uplifted to an elevation of 11,755 feet. It forms the natural watershed between the Arie, a branch of the Rhone River, and the Dora Riparia, a tributary of the Po River. The flanks of the mountain are rather heavily forested.

It is famous for the nearby Mount Cenis Pass, 6,765 feet above the sea, used from ancient times down to the present as one of the gateways from the north into Italy. So favorable was its location that it was chosen by Napoleon I as the site of a fine highway built by his order during the years 1803-1810. With the development of railways, however, this highway proved quite inadequate as an artery of commerce and the present tunnel became a major project.

The spot chosen underlay the Col de Fréjus, about 15 miles southwest of the main peak, and here King Victor Emmanuel II exploded the first mine in a ceremony marking the start of construction in August 1857. As the entrance on the French side lies at an altitude of 3,801 feet, while that on the Italian side is 4,246 feet, laborious calculations involving both elevation and direction were necessary, consuming more than a year. So accurately were they conducted, however, that when work crews, operating from both ends of the tunnel, met on Christmas Day 1870, the floor and walls coincided exactly.

The length of the tunnel is 42,145 feet, or nearly eight miles, from Modane, France, to a point near Bardonnecchia, Italy. The height is a minimum of 24 feet, 7 inches, while the width, varying from 25 to 26 feet, accommodates a double track. Both walls and roof are lined with masonry more than two feet thick, and the floor, where necessary, is strengthened with arches. To facilitate drainage, the tunnel slopes 128 feet to the south and 473 feet to the north from its mid-elevation. About one eighth of the construction was completed by hand labor. Boring machines were then introduced. Nearly a hundred borings and more than a hundred pounds of gunpowder were required for each average yard of advance through the solid rock. The cost of the enterprise, 75 million francs, or some \$14,475,000, was shared by the French and Italian governments and by the Northern Railway Company of Italy. The tunnel was formally opened on Sept. 17, 1871, and remains a conspicuous monument to engineering skill.

CENOBITES, sĕn'ô-bīts (Gr. *koinos*, common + *bios*, life), religious men or women living in community for the practice of asceticism. Asceticism, not peculiar to any one creed or confession, represents an attempt of the soul to achieve union with God. Cenobites seek to attain this end rather by social than by individual means. Though known in paganism and Judaism also, cenobites have flourished chiefly among Christians. Their system developed into monasticism which played a prominent role in medieval church history. The greater number of religious ascetics in the modern Christian church are cenobites, although some exemplars of the eremitical (hermit) or semi-eremitical life remain.

CENOGENESIS, sĕ-nô-jĕn'ĕ-sīs. Among many of the animals which during post-embryonic growth pass through a series of stages similar to the ancestral forms of their types—a process known as palingenesis—there are certain species in which the different stages of growth or metamorphosis are crowded back to the embryo stage, or abbreviated, and the animals hatch or are born in the shape of their parents. This is cenogenesis.

Certain frogs, like the tree toad of Guadeloupe, W. I., where there are no marshes, do not pass through a tadpole stage, but hatch without tails, and with legs, and otherwise resemble their parents. The same is the case with certain shrimps and crabs, and is partly the case with the lobster. In all such instances the direct development is apparently due to a difference in the environment or other conditions of life, as for example, in certain crustacea, to a change from salt to fresh water.

CENOTAPH, sĕn'ô-táf (Gr. *kenos*, empty + *taphos*, burial), a monument erected in honor of a deceased person who is buried elsewhere or whose body cannot be recovered. Cenotaphs were often erected by the ancients, who believed that when the body was not buried the soul could not be admitted into the abodes of the blessed. The term is also applied today to monuments erected in memory of the men who have fallen in war.

CENOZOIC ERA, sĕ-nô-zō'ĭk, the last great division of geologic time, beginning about 60 or 70 million years ago. The name, meaning "recent life," was coined by John Phillips in 1840

and was spelled "Kainozoic," a form still widely used. The era is divided into the Tertiary and Quaternary periods, with the Paleocene, Eocene, Oligocene, Miocene, and Pliocene epochs assigned to the former, and the Pleistocene to the latter. (See separate articles on each of these periods and epochs.)

Life in the earliest Cenozoic differed from that of the latest Mesozoic just preceding in various degrees. There were small changes such as are invariably present in the geologic succession, in which kinds of close relatives modify from ancestor to descendant. Such differences may be sufficient to permit separation of the earlier Cretaceous period from the Paleocene, but may be no greater than those reflecting differences of climate rather than time. Abrupt changes in which characteristic forms vanish completely without leaving lineal descendants are more definitive. Such changes are exemplified by the ammonoid cephalopods. Though some of them may have survived the Mesozoic, and some rocks of the Paleocene may mistakenly be called Cretaceous because of their presence, they never attained the abundance they enjoyed throughout the Mesozoic. And the dinosaurs, great reptiles on Mesozoic lands, have never been found in Paleocene in America and only doubtfully in Europe.

The average life in the Cenozoic soon became quite unlike that of the preceding era. In the seas the differences at first were negative ones, such as the absence of ammonites. Disc-shaped one-celled animals, orbitoid foraminifera like the nummulites that fill the limestone of the pyramids, grew in the warmer seas; a few of these had lived in the Cretaceous. But these contrasts would not strike the average observer.

On the lands, the forests of the Paleocene had many of the deciduous trees that dominate present forests of similar climates—poplars, oaks, maples, birches, and their associates. The conifer *Sequoia*, of limited present range in North America, spread over larger regions. And there were grasses and herbivorous plants on the plains such as had appeared before and still abound.

It was in the vertebrate inhabitants of the forests and plains that Cenozoic life introduced the greatest changes. The mammals had existed during the Mesozoic as obscure little animals, insignificant in numbers and size in comparison with the great dinosaurs and other reptiles. Some kinds of reptiles lived on, such as turtles, snakes, and crocodiles, but the greatest died. Soon the mammals developed into many varieties, some to become immense and grotesque, and vanish. Amblypods, huge, clumsy hoofed beasts somewhat resembling the hippopotamus, but only distantly related, did not survive the Eocene. Titanotheres, elephantlike creatures having long nasal projections resembling tusks, roamed Oligocene plains and are preserved in the clays of the Dakota Badlands, their last resort. Mammals ancestral to the elephants were small and undistinguished in the Miocene, migrants from Asia where they had been since Eocene; their tusks and trunks lengthened as their size increased. Similarly a little doglike animal in time grew larger, acquiring a longer head and legs and high-crowned teeth, and losing toes until it was the fleet one-toed horse. The record of man is not as well authenticated; perhaps his ancestors were tree-dwellers whose skeletons were not as frequently buried. Some primates have been found in Tertiary rocks in scattered regions, but the first resembling

modern man is from the Pliocene or early Pleistocene, a small fraction of the time since the beginning of the Cenozoic.

CENSER, sĕn'sĕr, a vessel in which incense is burned. Censers were employed by the Jewish priests for presenting incense to the Lord in the sanctuary. Flavius Josephus tells us that King Solomon made 20,000 gold censers for the temple of Jerusalem to offer perfumes in, and 50,000 others to carry fire in. Censers, or thuribles, are used in some modern churches, especially in the Roman Catholic Church at mass, vespers, and on other occasions. They are suspended from chains, by which they are swung about in the hand to spread the incense in all directions. They are usually made of brass or copper, sometimes of silver or gold. Of their precise shape before the 12th century there is little record. The earliest ones are richly decorated, set with jewels and sometimes made in the form of small churches. They were also often made in two hollow halves and shaped like a ball. The upper half varies very much in form. The lower half holds the charcoal and the incense, while the upper half is perforated with holes to allow the smoke to escape.

CENSORS (Lat. *censores*), high officials in ancient Rome during the republican period. Unlike other magistrates two censors were elected for 18 months (not for a year), once in five years. Among their official duties the most important were: registration of citizens, their families, and property for military and taxation purposes for a five-year period (*lustrum*), and control of public morals (*regimen morum*). As censors of morals they had authority to brand citizens with a *nota censoria* for bad treatment of wives, children, or slaves, luxurious living, misdemeanor in office, embezzlement in guardianship or partnership, and other offenses. The censorial blame produced manifold disadvantages to, and disqualifications of, the persons censured. Of great political importance was the privilege accorded the censors of keeping and revising periodically the lists of senators (*lectio senatus*) which became their exclusive right in the late 4th century B.C. They not only confirmed the actual membership of the senate but might also select new senators among the best (*optimi*) citizens and exclude others by a *nota censoria* for bad conduct. The vacancies thus created were filled by the censors' appointment of new members. In the field of financial administration, the censors concluded agreements concerning sales and leases of state property (public land, mines, quarries) with private individuals, and agreements concerning the collection of taxes and customs duties with tax-farmers (*publicani*). Construction of public buildings, roads and bridges was also under their supervision. During the final three and a half years of a *lustrum*, when the censorship was vacant, the censors' duties were accomplished by other high magistrates (consuls, praetors). Originally censorship was a patrician magistracy, but as early as 356 B.C. a plebeian censor was elected. In the early Principate censors appear only sporadically and with very limited functions.

(Philadelphia

A. BERGER.

CENSORSHIP. In a strict sense censorship is the term applied to the operations of a person or a board or committee of persons authorized to intervene between a producer of publishable material and the consumers to whom he offers that material, and to prohibit either the producer from publishing, or the consumer from reading, hearing, or otherwise acquiring knowledge of whatever part of such material the censor deems unsuitable. The censor may be authorized by a sovereign government (or by virtue of powers delegated by that government to a lesser government, such as a municipality), or by a nongovernmental organization such as a church or secular society, possessing large power to command the obedience of its members or followers. Censorship of this kind operates before the material is communicated to the consumer, and is therefore described as *preventive censorship*. It requires a censor or body of censors invested with large discretionary powers and not merely interpreting, as a court does, the language of a general statute.

In a looser sense the term has come to be applied to the whole process of the enactment and subsequent enforcement of laws limiting the freedom to publish, except in so far as they are concerned with the protection of the rights of others, as in the case of libel, slander, breach of copyright, or incitement to violence. In this sense censorship involves no censor, for judgment as to publishability is made by a jury or judge, enforced by punishment, subject to appeal, and limited by a reasonable interpretation of the language of a general statute. This is termed *punitive censorship*. But the language of the law may be so broad, and the latitude of interpretation so great, as to leave little difference in effect between this method and the employment of a censor with unfettered discretion. Punitive censorship is of course an exercise of the sovereign power of the state.

Censorship may be, and has been, applied to any and all means of communication, from human speech to modern developments like television, and including all the arts. (Even music appears to be censored in Russia.) The term publication means the act of communicating or offering to communicate by any of these means, usually to the public in general. Communication to a single recipient, as by letter or private conversation, is not ordinarily regarded as publication, though in wartime, when the reasons for censorship are different, it may become censorable. The private censorships cannot prevent publication of disapproved material, but they can call upon those persons who accept their judgment—the members of the religious body or the supporters of the society—to refuse to consume it. This operation is really more in the nature of a boycott than of a censorship, but the prospect of such a boycott frequently has the effect of dissuading the publisher from publishing or his distributing agent (bookseller or moving picture exhibitor) from offering the work in certain territories. Such private censorship may thus have an important influence in limiting the selection of material offered to the public, especially in the mass media where production is very costly and the largest possible audience is required. It is probably less restrictive in the case of books, especially those of a serious nature. A kind of private censorship is exercised also by libraries, art galleries, and similar institutions, when they exclude from circulation or exhibition certain works on the ground,

not that the public would not want to read or see them, but that such work would not be good for the public.

Indirect Censorship.—Public authorities often exercise censorship by the use of powers originally granted for quite different purposes. The state's control of imports, and of certain means of communication such as the post office, is commonly used for purposes of censorship, sometimes without any appeal to the courts. In the United States this method is limited by the guarantee of free speech (which has been interpreted as extending to free communication by a great variety of means) in the Bill of Rights, but most other countries have no such limitation. The United States Tariff Act prohibits importation of "obscene" matter, but an amendment of 1930 assigned the determination of obscenity to the courts, and in 1931 James Joyce's *Ulysses*, previously banned, was declared admissible. The Secretary of the Treasury may moreover admit "the so-called classics or books of recognized and established literary merit" even though obscene, but may in his discretion confine their importation to non-commercial purposes. In Canada the Customs Department maintains a prohibited list containing many books which have never been submitted to court judgment, and which if manufactured in Canada would have to be condemned by the courts before they could be suppressed; William Faulkner's *Sanctuary* is an example.

The police power to license halls and public meetings and the distribution of pamphlets in public places has often been used to prevent the holding of meetings and the distribution of literature by strikers or by an unpopular religious or political sect. The United States Post Office forbids the transmission by mail of many classes of matter not otherwise unlawful. The municipal licensing of theaters has been widely used to control the entertainment provided in them. If the authorities desire to disclaim any interest in the nature of the show, they can always find some grounds in the fire regulations on which to close or threaten to close the theater. In Boston there is a frank censorship by a board consisting of the police commissioner, two captains and a clerk, but since 1938 the regulations have required at least one public performance and a hearing before the license can be cancelled. Eugene O'Neill's *Strange Interlude* and many other classics of the American theater have been kept off the stage in Boston. In 1931 the New York City Commissioner of Licenses threatened newsstands with cancellation of their licenses if they were found guilty of selling lewd and obscene literature.

New Modes of Communication.—Prior to 1900 the available modes of public communication were practically confined to the spoken word, the theatrical performance, the printed book, the periodical, and the public exhibition of works of art. Both the theater and the printing press were traditionally subject to censorship by license in almost all countries until the rise of liberal opinion in the 18th century, and the licensing of plays by the lord chamberlain continues a sole relic of that system in Great Britain, where the licensing act for the press expired in 1695 and some surviving powers of the government over newspapers were declared illegal in 1765. The present policy both in Great Britain (except in the theater) and in the United States is based on the assumption that anything may be published

which does not infringe the rights of other persons, offend public morals, or promote sedition.

All of these older methods of communication have the common characteristic that anybody who can pay for it, can have the use of a theater, a hall, or a printing press. The process of communication by radio, discovered and developed after 1900, lacks this characteristic. The number of wave lengths or channels available in any given area is limited, and the effective use of any one of them requires that the user be protected against any other broadcasting on the same channel in the same area—a protection which can be provided only by the authority of the state and often requires treaty action by several nations. The licensing of radio and television stations is therefore indispensable. The number of stations being limited, the principle of free speech will not operate automatically; a man who cannot obtain access to any existing station cannot go out and get himself a new station, as he could a printing press. The state has therefore had to concern itself with the problem of securing a reasonable freedom of access to radio and television for all kinds of different ideas and opinions. Great Britain has sought to do this by means of the operation and control of the whole radio system by a government monopoly, the British Broadcasting Corporation, and nothing can be broadcast except by that body. Canada has set up the Canadian Broadcasting Corporation owning and operating a number of important stations and possessing large powers of control over the remaining stations in private hands. In both countries there is therefore a very direct control over what is broadcast, but in practice the private stations in Canada are very little interfered with except by general regulations, and there is no precensorship of broadcast material. (It would have little effect in any case, since almost all Canadian listeners can reach United States stations.)

In the United States the Federal Communications Commission, established by an act of 1934, was given power to license stations for limited periods and to refuse renewal in case of certain types of misbehavior, but was specifically forbidden to exercise censorship. The act does not however forbid the commission to evaluate the total performance of a station in considering renewal. The Commission on Freedom of the Press organized by the University of Chicago in 1944–1945 recommended that the constitutional guarantee of freedom of speech should be extended to cover radio and motion pictures; in 1953 the Supreme Court adopted this view concerning the latter, but the limitation of wave lengths makes its application very difficult in radio and television. How can a man have a right to say something over the air, unless there is some particular radio station upon which he can enforce that right, and, if he has that right, what becomes of the freedom of the radio station?

The financial structure of the radio and television industry, wholly dependent on revenue from advertisers if in private hands, and on revenue from taxes if in public hands, is a strong guarantee against misbehavior of the kind which, if indulged in to any extent, would call for censorship. Radio and television are unique in this second respect, that they alone among means of communication are never paid for by the consumer. The product is delivered free of charge into the consumer's home, and the producer's tendency is to avoid anything which would give the slightest offense to any

class of listener. Broadcasting's great weakness is not that it needs censorship, but that it never does anything which would make anybody want to censor it. The complaint of liberals in the United States about it is that, like the motion picture industry, it over-censors itself, in an effort to avoid anything disturbing to listener or viewer.

The motion picture in the United States is also accused of over-censoring itself, but for an entirely different reason. Internal censorship in the movies is an effort to avoid the economic consequences of an excessive and varying censorship by public authorities in many different localities. The motion picture in its infancy was not treated as a serious art form. It is not therefore surprising that in 1915 the United States Supreme Court did not consider it entitled to the constitutional guarantees of free speech, and thus opened the door to censorship by individual states or municipalities. (The later reversal of this decision appears to deprive the censors of their power to prohibit absolutely the exhibition of disapproved films or sections of films in their jurisdiction, but such exhibition can be made difficult by other means.) The provinces of Canada exercise the same right of censorship, and there is no Bill of Rights to hamper them. In Great Britain there is only the general decency law as enforced by the courts.

The early and widespread development of movie censorship was partly due to the fact that in this industry the act of publication takes place in two stages, first the performing and recording, and second the exhibition of the resultant film. These two stages may take place in different jurisdictions with radically different attitudes on public morals. Each jurisdiction seeks to protect its own moral code by setting up and enforcing its own standards. The film when once manufactured is incapable of being altered except by cutting, a process which may be very detrimental to its entertainment value. American film producers therefore try to mitigate the effects of local censorships by imposing upon themselves a voluntary censorship of a third type not yet mentioned in this article, namely *industrial censorship* or censorship by an organization of producers of the censored material. The Breen Office administers the Breen Code, and withholds its seal of approval from all films which it considers to fall short of full compliance. It cannot prohibit the exhibition of unapproved films, but exhibitors who make a practice of showing them may find their supply of films from the major producers cut down. Another instrument of film censorship, belonging to the type which works upon the consumer, is the Legion of Decency, formed by the Roman Catholic Church and the National Federation of Churches, which by blacklisting can cut down attendance and even, where it is sufficiently strong, induce exhibitors not to show a film.

Reason for Censorship.—The reason for censorship in general (other than wartime censorship, which is an entirely separate matter) is the desire to protect the public or a certain section of it from the evils which are supposed to flow from the communication of disapproved ideas or concepts, and the reason for preventive censorship in particular is that these ideas or concepts are considered too dangerous to be allowed currency even during the time necessary for their examination by the courts. In the 19th century the grounds for disapproval were usually related to public morals, although in British countries and

in Europe there was also a tendency to object to extreme or revolutionary criticism of the nation's political institutions. The United States with its revolutionary tradition put less accent on this aspect. But since the development of the ideological "cold war" between the Communist totalitarian states and the liberal democracies, all the latter, in varying degrees, have become apprehensive about the spread of subversive theories. The political concepts of these two groups of nations are based upon incompatible doctrines of the relations between men and society, and conversion to a new doctrine involves disloyalty to the political institutions of the older one. Even a democratic society now feels called upon to adopt strong measures to prevent the spread of anti-democratic ideas in its territory, not so much from the fear that these ideas will win the support of a majority as from the fear that their holders may acquire control of the machinery of government by conspiracy and force, as has happened in several once democratic countries. This is a real danger, but so also is the danger that by a too rigid suppression of all that is suspected of totalitarian tendencies one may suppress that free play of criticism, that tolerance of new and at first unpopular ideas, which are essential to the permanent functioning of democracy. Thus the Chicago Commission on Freedom of the Press recommended that the laws against utterances favoring revolutionary change should be amended so as not to apply "where there is no clear and present danger of violence resulting." As they stand, such laws can be interpreted as banning the works of Karl Marx and Georges Sorel as rigidly as they would ban a contemporary pamphlet calling on American citizens to rise and massacre shareholders of a large corporation.

The censoring of material from the point of view of sex morals, it has been pointed out by social scientists, coincides closely with the rise to political predominance of the middle classes. A dominant aristocracy seldom concerns itself much about that subject. One reason may be that the position of the middle class can be maintained from generation to generation only by those qualities of thrift, prudence, and self-control which are most threatened by sexual laxity. Andrew Lang pointed out long ago that "English literature had been at least as free-spoken as any other to the death of Smollett (1771). Then, in twenty years at most, English literature became the most 'pudibond', the most respectful of the young person's blush, that the world has ever known." The change was duly but slowly registered in law and court decisions. A Society for the Suppression of Vice was formed in 1802. (Its American counterpart, under Anthony Comstock, did not come until 1873.) In 1857 Lord Campbell's Act replaced the old common law on indecency, and in 1878 a decision of Lord Chief Justice Cockburn (still followed) defined obscenity as the tendency "to deprave and corrupt those whose minds are open to such immoral influences and into whose hands a publication of this sort may fall." This has compelled the courts in all British countries to consider the effect of the work, not on the ordinary reader, the *homme moyen sensuel* of French jurisprudence, but on those, perhaps relatively few, whose minds are open to evil influences. Under the influence of this decision a great number of works of fiction have been condemned in Great Britain and their publishers subjected to severe loss, heavy fines and often imprisonment, and scientific works have been

either condemned or permitted only for sale to qualified persons. Until about a generation ago the United States courts followed the same tendency, but they have now shaken themselves free from it, and also from the practice of considering the effect of isolated passages rather than that of the work as a whole. Thomas Hardy's *Tess of the d'Urbervilles* (1891) had to be expurgated for American publication, but today the American publisher enjoys much more freedom, especially in the matter of language, than his British counterpart, and several British authors, Richard Aldington among them, publish in the United States first and submit to expurgation in Great Britain later.

A further reason for the spread of censorship in the sphere of sex morals in the last half-century has been the immense increase in the freedom of action of the adolescent age-group and in their command of money. Before 1900 the dime novel was almost the only form of entertainment on which the adolescent spent his own money. If he bought a more costly book or went to a theater it would be with his parents' consent and money. Today in English-speaking countries the juvenile goes to the movies, perhaps several times a week, with his own money and alone, and buys his own magazines and paper-covered novels. The family having surrendered its guardianship of these youngsters, there is room for the contention that the state must take over. Unfortunately it has nowhere been found possible to apply the restrictions to juveniles alone, and the effort to protect their morals often leads to suppression of serious works which should be available to adults. After World War II the tremendous growth in the field of comic book publishing was accompanied by increasing public concern over the content and quality of some of these books. Various groups demanded either imposition of regulatory codes on comic book publishers or voluntary adoption of certain rules and standards by the publishers. United States Congressional committees held hearings in an effort to determine whether legislation was needed to regulate comics publishing. In Canada the House of Commons passed a bill in 1949 which outlawed crime comics, but in the same year Gov. Thomas E. Dewey of New York vetoed as unconstitutional a bill which required that publishers of comics be licensed.

One other area of censorship about which there has been a great reversal of opinion in the last forty years is birth control. Advocacy of and instruction in birth control was almost universally banned until near the turn of the century, but today in all but predominantly Catholic countries it is almost universally tolerated, except in such restricted fields as radio and motion pictures. The objection to it is no longer based on obscenity but on purely ethical or religious grounds. Thus in Ireland, under the Censorship of Publications Act of 1929, the Minister of Justice has an advisory board which reports to him when it finds that any publication is indecent or obscene or advocates the prevention of conception, or when any periodical devotes "an unduly large amount of space to the publication of matter relating to crime." The minister may then make a prohibition order. Obscenity is given a very wide interpretation in Ireland, and there is a long list of books, many of them highly regarded elsewhere and many of them by Irish authors, which are banned from Ireland by such orders. Indirect censorship

against birth control information, by exclusion from the mails, began in the United States with the Comstock Law in 1873.

Wartime Censorship.—Censorship of the press in time of war rests upon entirely different grounds and is of an entirely different character from ordinary censorship in liberal countries. It has two main objects, both peculiar to the state of war: (1) to prevent the enemy from acquiring knowledge of military value, and (2) to prevent the circulation of matter calculated to weaken the national morale in the home country. The first object is generally regarded as having an absolute priority; nothing should be published which could convey information of importance to the enemy. The second may conflict with another object which also has large claims, namely the requirement that the public should have enough knowledge of the current situation to enable it to criticize and improve the conduct of the administration. The change of government which brought about a great improvement in the munitions supply of Great Britain in World War I could not have been effected without first breaking down some of the censorship restrictions.

Even in time of peace it may be desirable for a nation to keep certain kinds of knowledge from potential enemies. In totalitarian countries this is effected by censorship, but in liberal countries there is a reluctance to employ this kind of censorship in normal times, and the purpose is attained by restricting the knowledge of such matters to persons who can be relied on to maintain secrecy. The total amount of such knowledge is now extremely large, including large areas of science as well as purely military matters, and hence arises the "security" problem which has so plagued democratic countries since World War II. In 1951 President Harry S. Truman issued an executive order requiring all civilian agencies of the United States government to tighten control over releases of information which might affect national security. Only the State and Defense departments and the Atomic Energy Commission had previously been subject to such rules. The order of the president was widely criticized as censorship. President Dwight D. Eisenhower issued an executive order in 1953 defining the categories of classified material set up in the earlier order and also removing from many agencies the authority to classify information.

Wartime censorship is concerned to prevent the communication of knowledge, not merely to the public at large, but to a single unauthorized person. It has therefore to prevent not merely publication, but also person-to-person communication, of matter which it is desired to keep from the enemy. It thus involves scrutiny of private correspondence, especially such as crosses national borders. In this operation it pursues also a third object, namely the procuring of information useful to the administration, and so becomes an investigatory agency.

Governments with constitutionally limited powers frequently have difficulty in overcoming these limitations to meet their wartime needs. The United States Constitution contains little provision for enlarging the powers of the central government in time of war; even the suspension of habeas corpus is authorized only for rebellion or invasion, not for war at a distance. Canada has a similar situation, though in the absence of a Bill of Rights for the individual there are only the rights of the provinces to be considered; but

Canada has overcome the difficulty by the invention of the doctrine of emergency powers (nowhere mentioned in the constitution) which enables the national government to do practically anything by declaring a state of emergency. (The courts have upheld an order-in-council compelling native-born Canadian citizens, of Japanese ancestry, to submit to deportation to Japan, but it was never put into effect.) In Great Britain the powers of Parliament are unlimited.

In the United States it is doubtful whether some of the convictions in World War I under the Sedition and Espionage Acts were strictly constitutional under the Bill of Rights. In World War II these acts were more strictly construed, and a decision of the Supreme Court in *Hartzell versus United States* (1944) showed a due concern for the maintenance of civil liberties. To some extent this improvement may have been due to a greater unanimity of opinion in favor of the war than existed in the earlier conflict. In the absence of safe constitutional ground for proceeding against periodicals by direct action the government in World War I fell back largely on the power to exclude from the mails. This was conferred on the postmaster general, with no court appeal allowed, in the case of any person making false statements about the armed forces, encouraging disloyalty, or in other ways interfering with the prosecution of the war. Exclusion from the mails is an instrument which can be used for the total suppression of a periodical with a widespread circulation, and more than 100 periodicals were thus excluded in 1917-1918. In World War II the use of this device was much more moderate, but *Social Justice*, the organ of the Rev. Charles Coughlin, was deprived of second-class mailing privileges along with a few other papers. In both these wars the actual direct censorship of the press in the United States, in the sense of excluding matter which the government desired not to be printed, was "voluntary," effected by the free cooperation of the newspapers themselves, but behind the persuasive force of the Censorship Board under George Creel (1917) and the Office of Censorship under Byron Price (1941) was always the power to exclude from the mails. An interesting example of cooperation was the withdrawal of certain "public participation programs" from radio because of the risk that messages might be sent to the enemy by code.

In Great Britain, situated within the theater of active hostilities, the government made a much more direct use of its unlimited powers. Nothing could be printed within the country or sent out of the country by any means without being passed by an official censor; an immense staff was employed for this purpose, and it was said that at one time during World War II the only leakages of military information were those which occurred through inadvertent mention of the location of individual members of the armed forces in local parish magazines which no censor could possibly find time to examine.

At the start of the Korean War in June 1950, the only censorship of correspondents covering news at the front was a voluntary one. The individual reporter was trusted to decide what should be included in or omitted from his dispatch. The members of the press, however, experienced difficulties in applying proper security standards, and it soon appeared that different correspondents had imposed on themselves unequal restraints. The result was that

some reporters filed exclusive stories dealing with matters which other reporters had hesitated to use on security grounds. In December 1950 the order was changed to impose a full military censorship after many complaints from the correspondents and because of certain instances of abuse, in one case the news of a general's death having been published before his widow had received official notification.

In the totalitarian countries, since the individual citizen is not supposed to have any right either to free expression or to the receipt of information other than what the government thinks fit to allow him, censorship presents no difficulties, and in Japan, accustomed for generations to a high degree of discipline, the concept of "thought control" in the national interest was openly adopted as government policy until the surrender of 1945. In Russia the periodical press is practically an agency of the government. A correspondent of Tass, the Russian news bureau, was for that reason expelled from the parliamentary press gallery at Ottawa in 1950, but his successor, with somewhat different credentials, was granted admission.

Censorship in History.—Governments have at all times sought to restrain the spread of ideas considered likely to undermine their authority. That authority was usually associated also with the predominance of a certain religious belief, and criticism of that belief was commonly repressed. In Athens in 399 B.C., Socrates was sentenced to death for impiety and corruption of youth. The Roman Empire from Augustus to Constantine was tolerant of all kinds of religious observances but required everybody to sacrifice to the divinity of the emperor on pain of death, and suppressed many writings as dangerous to the imperial authority. Throughout the medieval period the Roman Catholic Church prohibited the circulation of heretical works, but it was not until the invention of printing that the procedure for dealing with them became systematic. The rapid multiplication and wide circulation of printed books became embarrassing to both the religious and the secular authorities, and in 1501 a papal bull established the principle of licensing for all printing. In 1564 there was issued with papal approval a report of a committee of the Council of Trent bearing the title *Index Librorum Prohibitorum*, which still continues to designate the list of books which Catholics are prohibited to read except under very special circumstances. The periodical revision of this list is now in the hands of the Congregation of the Index, a body composed of several cardinals with numerous consultants and examiners. In the enforcement of these prohibitions the church was at first usually supported by the secular authorities, but since the Reformation the increasing separation of church and state, and the monopoly of legislative power by the latter, have in most countries reduced the prohibitions to a moral rather than a legal obligation, and left printers free to issue their products without any reference to ecclesiastical authority.

In England the Reformation at first merely transferred the power of licensing from the Catholic Church to the monarch, who became the head of the Church of England. Elizabeth I confined the right of printing to London, Oxford, and Cambridge, and authorized the Messengers of the Press to enter houses in search of uncensored presses and publications. The Long Par-

liament followed the same policy, and Milton's *Areopagitica*, the classic work on freedom of publication, was a reaction to a parliamentary ordinance of 1643. The licensing policy thereafter met with growing resistance, and for several short periods the Licensing Act failed to be renewed, but it was not finally abandoned until 1695, a date which marks the definite establishment of the principle of freedom of the press in England. The monopoly license to print was then the only existing form of copyright, and a period of widespread piratical printing followed until the first copyright act in 1709. Developments in Scotland followed the same course up to the time of the Union, but the penalties were even more severe, and in 1585 a libelous writing against the king was punishable with death. The power to license works treating of religion was granted to the General Assembly of the Kirk.

France, although it remained Catholic, saw the same process of transfer of the licensing power to the secular authority. An ordinance of 1566 vested in the crown the licensing of theological works previously held by the University of Paris. It was in his capacity of Minister of the Crown that Cardinal Richelieu in 1629 made it a capital offence to publish a work against religion or the state. In France the Revolution abolished all restraints on publication, but this speedily proved unworkable, and throughout the 19th century the successive changes of constitution were accompanied by corresponding changes in the form and degree of press control. During World War I France had an example of what is perhaps the most futile of all forms of censorship in a liberal country—the entire suppression of a powerful newspaper—when Clemenceau's *L'Homme Libre* was stopped, only to be immediately followed by *L'Homme Enchaîné*.

In Canada there was no printing press until the end of the French regime. In the British colonies of North America which later became the United States the governors exercised the licensing power, but only against increasing opposition from hostile public opinion, and by the time of the American Revolution the idea of a free press was already firmly established in all parts of the new republic. As Canada remained under British control it developed there more slowly, but by 1826 the government in Upper Canada was already finding it difficult to enforce control of the press by action through the courts. In an effort to silence William Lyon Mackenzie, the leading Opposition journalist, the ruling faction in that year resorted to a mob attack on the premises of his *Colonial Advocate*, for which he succeeded in recovering substantial damages. The governing party then adopted the method of repeatedly expelling him from the Legislative Assembly, to which he was consistently re-elected. These actions had a good deal to do with the outbreak of the Rebellion of 1837, and after the disorders of that period had died down little more was heard of restrictions on the liberty of the press. In 1938, however, the province of Quebec adopted the so-called Padlock Law which enables the attorney general to close at his discretion any building which he finds to be used for Communist propaganda, and some years later the same government authorized him to seize copies of any periodical offending against certain standards of decency. The Quebec Board of Censors has prohibited the showing of the films *Enfants du Paradis* and *Martin Luther*.

Problems of the Future.—The 19th century liberal attitude towards censorship rested on the assumption that the interests of the competing owners of the means of dissemination would, if not interfered with, bring about an adequate "diversity of access" to the means of communication. Liberals in the 20th century are inclined to question that assumption, especially in regard to the mass media of radio, television, and the motion picture, on the ground that ownership is becoming too centralized and competition does not operate as it once did. Daily newspapers are diminishing in numbers in all English-speaking countries, and the remainder are being more and more organized into "chains," under one ownership or direction. Radio and television stations are usually affiliated to one or another of the networks. The financial relations between newspapers, radio, and television are very intimate. The motion picture industry is highly centralized. Morris L. Ernst in *The First Freedom* says that the high prices for time on radio stations "seriously prevent diversity of access to the ether." The *Code of the National Association of Broadcasters* (1939) says that "Time for the presentation of controversial issues shall not be sold except for political broadcasts"; this is to prevent embarrassing demands for time for a reply. Under this regulation labor, with no political party and with three rival organizational groups, has little chance of presenting its message on the air.

Proposals for remedying this condition have ranged from legislative dissolution of all large combinations in the communications business to the placing of radio and television under the free speech guarantee. Even if all the chains and networks were dissolved there would still remain the highly centralized influence of great advertisers, who can hardly be expected to be favorable to all types of controversial material. As regards the radio-newspaper relation, it is significant that the Canadian Broadcasting Corporation, though instructed by Parliament to favor separation, in practice often finds the local newspaper the best applicant for a license, in respect of ability to provide good service. To retain its advertisers the radio station must retain its listeners, and it is unlikely that under any type of control it could afford to devote much time to controversial material of a possibly unpopular type. Yet the British solution, of public ownership and control and no advertising on radio,¹ is scarcely likely to satisfy the American listener; and even the British method is not an absolute guarantee of diversity of access—the ability of all shades of opinion to reach the public by all media.

B. K. SANDWELL,

Editor Emeritus, "Saturday Night," Toronto.

¹ On June 30, 1954, the British government permitted advertising on television, limited to the time between programs and involving no sponsorship of programs.

CENSURE, in canon law, a spiritual penalty whereby a contumacious offender is denied the use of certain spiritual goods. It has three degrees—excommunication, suspension, and interdict. By excommunication the offender is cut off from association with the faithful whether in spiritual things or in secular; by suspension a minister of the church, a cleric, is deprived of the right to exercise the functions of his station; by interdict the services and ministrations of the church are denied to an offender—the sacraments and the right to Christian burial. An interdict may affect places as well as persons; it may be laid on a church edifice or a burial place. Censures are the penalties prescribed in the church's law for definite offenses, and some censures fall upon the offender, *ipso facto* or *ex ipso jure*, without need of a judgment being pronounced by church authorities. Such a censure is said to be *latae sententiae*, that is, providing for its own carrying out; but most censures are *ferendae sententiae*, requiring that the sentence be pronounced by some proper authority, as the bishop of a diocese or his deputy. And absolution from some censures *latae sententiae* is reserved to the supreme pontiff, while absolution of other censures can be given by bishops, or other pastors, either in the ordinary course of their jurisdiction or in virtue of special faculties accorded to them to that end. An example of a censure, release from which is reserved strictly to the supreme pontiff himself, is the censure of excommunication incurred by whoever violently assaults a cleric or a member of a religious order (*clericus vel monachus*); but an exception is made of the case where the offender is in danger of death.

CENSUS. The practice by governments of enumerating populations under their jurisdiction and of taking account of the economic assets and social characteristics of the people has become a highly scientific operation in modern times. Today, more than 80 countries of the world conduct censuses of varying frequencies. Under the leadership of the United Nations throughout the world, and specifically of the United States in the Americas, efforts to coordinate the timing of censuses have met with some success. More than 60 nations now are cooperating in development of time schedules and minimum standards, although there is still a wide variance among censuses in method and quality. Sufficient progress has been made, however, to enable demographers to arrive at a reasonably acceptable population total for the world, approximately 2½ billion human beings. This figure is based in large part on enumerations and for the rest on carefully constructed estimates. The importance of maintaining current vital statistics (natality and mortality data) to determine rates for measuring trends with reference to fixed censuses also has gained universal recognition.

HISTORY OF CENSUS-TAKING

The word *census* is derived from the Latin, *censere*, to value or tax. Roman magistrates, known as *censors*, were charged with making a register of the people and of their property, at five-year intervals, for the purpose of imposing taxes and to determine the number of males available for military service. Servius Tullius, the sixth king of Rome (578–534 B.C.), instituted the Roman census. Caesar Augustus, in 5 B.C., extended the census to include the entire Roman

Empire, and it was for the purpose of registering in such an enumeration that Joseph and Mary had come to Bethlehem when the infant Jesus was born.

The Earliest Surveys.—Censuses, in the form of cadastral surveys, had their beginning, however, long before the founding of Rome. References to the earliest of such surveys are vague. Ancient Babylonia, China, and Egypt had such accountings 30 centuries before the birth of Christ. Herodotus told of such undertakings in the valley of the Nile and in ancient Persia.

The Book of Numbers in the Old Testament is a form of census record. At the time of the Exodus (c.1500 B.C.) Moses enumerated the fighting men of Israel and the priestly Levites. Five centuries later, King David ordered the unwilling Joab to make a count of the Israelites to determine the number of his swordsmen. Biblical history states that this enumeration caused divine wrath to be visited upon the people, and this account provided a basis in later centuries for public resistance to censuses. Obviously, the fact that these earlier censuses were preliminary to military drafts and tax assessments had something to do with this resistance. In Rome, for instance, the censors ordered the observance of the *lustrum*, a feast of purification dedicated to the war god, Mars, at the conclusion of each census. The last *lustrum* was conducted in the year 74 A.D.

The collapse of the Roman Empire brought an end to the first known series of periodic censuses. The feudal system which followed rendered the revival of census-taking, even when practicable, less necessary. The *Breviary* of Charlemagne (c.808 A.D.) was one of the medieval efforts to revive such accountings. In the *Domesday Book* (1086 A.D.) William the Conqueror set up a census-like record of the names of English proprietors with a description of their lands, extent, value, and liabilities. The *Domesday of St. Paul's* (1181 A.D.) is another example. Genghis Khan caused censuses to be made of the people and possessions in territories overrun by his armies during the latter years of the 12th century and the early decades of the 13th century, and records dating from 1370 A.D. reveal detailed plans for a census in China, although it is not certain whether this census was completed. One of the earliest complete censuses of a city, involving inhabitants of all age groups, was taken in Nürnberg in 1449. Other provincial or municipal censuses were taken in Switzerland in the 15th and 16th centuries.

Western Hemisphere.—The first census in North America, of Spain's American possessions, was taken in 1576 at the behest of King Philip II of Spain. The Spanish overlords entrusted this task to the natives, and the report made by the Indian scribes is now in the University of Texas Latin-American Library.

Peruvian statisticians, however, have claimed recognition for their country as the locale of the earliest known censuses in the Western Hemisphere. This claim is based on the surviving records of the ancient Inca civilization in Peru and on historical writings of the Spanish conquerors who followed in the wake of Columbus' explorations. Records have been cited to show that the ancient Peruvians made a register of men for military purposes and reported their number to the Inca emperor, Sinchi Roca, as 200,000 fighting men.

Long before Columbus' voyage and the conquest of Peru by Pizarro, the Inca rulers appeared to have established extensive organizations devoted to reporting statistical information about their subjects and the resources of the Inca empire. Having no system of writing, the ancient Peruvians used the "quipus" to record census information. This contrivance consisted of a main cord from which hung, at certain distances, smaller cords of various colors, each having a special meaning (as red for soldiers, yellow for gold, white for silver, or green for corn). Knots were tied in the smaller cords representing definite numbers.

The first post-Columbian census in the Americas also had Peru as its base of operations. This census was conducted in 1548 by the Spanish viceroy, Don Pedro de la Gasca. This census and a second one in 1606 are described in an article by Carlos A. Uriarte, chief of the Demographic Statistics Department, National Directorate of Statistics of Peru, published (March 1949) in *Estadística*, official organ of the Inter American Statistical Institute.

American Colonies.—The first of the North American colonies to take a census was Virginia, in 1624–1625; a second census, taken in 1634–1635, enumerated 5,119 persons. The next colonial census was that of New York Colony, in 1698, which enumerated 18,067 inhabitants. These Virginia and New York censuses were the only colonial censuses to be taken during the 17th century in what is now the United States. Between 1700 and 1790, when the first United States census was taken, there were 36 additional colonial censuses. Nearly all of the American colonial censuses were taken at the behest of the British Board of Trade, which desired definite statistical information about the colonial market.

The colonial authorities of New York and Rhode Island developed the greatest aptitude for census-taking. Of the 38 colonial censuses before the 1st decennial census of the United States in 1790, nearly half were made in these two colonies—11 in New York, and 7 in Rhode Island.

Maryland took its first colonial census in 1712, with an enumeration of 46,073, and another in 1755. New Jersey was the fourth of the colonies to comply with orders that a census be taken, enumerating 32,442 inhabitants in 1726. The colonial governor had refused three years earlier to take the census as demanded by the British Board of Trade because "the people would take it as a repetition of David's sin." Upon the board's insistence, however, he issued orders to the sheriffs to take the census; and in all, three colonial censuses were subsequently taken in New Jersey.

The people of Connecticut and Massachusetts manifested considerable opposition to census projects. They feared that in some way the information gathered in censuses would be used to their disadvantage by the British authorities and saw no advantage to themselves. The first census including all the inhabitants of Connecticut was taken in 1756, while Massachusetts delayed until 1764 when the general court, after repeated demands from the colonial governor and fearing further to irritate British authority, ordered a general census in which Maine was included as a part of Massachusetts.

New Hampshire's first colonial census was taken in 1767 with a count of 52,700 inhabitants.

The colony took three additional censuses. One of these, in 1775, was taken to ascertain the quantity of arms and ammunition in the province and to correct (according to the 1909 report of *A Century of Population Growth*, issued by the United States Bureau of the Census) a "wild" estimate made by the Continental Congress of 102,000 inhabitants, exclusive of slaves.

Pennsylvania and Delaware, as well as the Southern colonies of Georgia and North and South Carolina, conducted no colonial censuses, as far as records show.

Canada.—Canada has advanced a claim to the first census in the modern manner with the enumeration in 1666 of the Colony of New France. This census provided a record of every person by name, on a fixed date, showing the age, sex, place of residence, occupation, and conjugal status. The original document of 154 pages, listing 3,215 individuals, is in the Archives of Paris. Thirty-seven complete and nine partial censuses were taken during the French regime; and these included data on agriculture, public building, sawmills, and other matters. Canada began taking a regular decennial census in 1851. Yearly estimates are made of the total population and that of each province. (See also CANADA—*Population*.)

Europe.—In the Scandinavian countries, the first of the modern censuses was taken in Iceland in 1703, but publication was delayed many years. For this reason, the Swedish census of 1750 (following the establishment of parish registers in 1686 and a supplementary law in 1748 which required parish tables to be kept on births, deaths, and total population) is regarded as the first which, since its inception, has constituted a regularly taken and periodically published population record. It is, like other Western European censuses, made up from the parish registers, a procedure recommended by Bishop Berzelius, one of the founders of the modern science of statistics. The founder of actuarial science, Richard Price, used the Swedish registry data to compile the first life insurance tables.

Various other partial censuses were taken in the 1700's, among them one in Austria in 1754, two in Spain in 1769 and 1798, and one each in Norway and Denmark in 1769. These were neither complete nor reliable, however. The first modern census in Prussia was taken in 1810; Norway, in 1815; Austria, in 1818; Greece, in 1836; Belgium, in 1846; Italy, in 1861; and Russia, in 1897. Actually, in Russia, a census had been ordered every 20 years after 1722. This was observed until 1782, and another was taken in 1796; but it was not until 1802 that a central bureau was established, after which Russian censuses were taken in various years prior to 1897.

Meanwhile in Great Britain various population counts had been made, although none had the characteristics of a general census. In 1791, Sir John Sinclair had undertaken to compile a census of the population, agriculture, trade, and industries of the entire kingdom by inquiries sent to the clergy of the Established Church. In 1798, 21 volumes of the results of this survey were published. His work led to Parliament's decision in 1800 to establish a census office, and Great Britain's first population census was taken in the spring of 1801. Britain's first census of agriculture and industry was not taken, however, until 1907.

France, also, took her first census in 1801, and another in 1806; but it was not until 1836 that reliable census-taking methods were adopted in that country.

THE UNITED STATES DECENNIAL CENSUS

The census in the United States had its inception as an integral part of the machinery of government. The Constitution provides that an enumeration of the population "be made within three years after the first meeting of the Congress of the United States and within every subsequent term of ten years" (Article I, Section 2). Such an enumeration is needed to determine the population of the various states, so that representatives in Congress can be apportioned among the states in proportion to their population.

The decennial census of the United States is the first of the modern censuses to be repeated at regular periodic intervals. Without lapse, the census of population has been taken at 10-year intervals since 1790. The first census of manufactures came in 1810, while the census of agriculture was initiated in 1840, the census of business was inaugurated in 1930, and the census of housing was first taken in 1940.

The 1st decennial census of the United States (1790) enumerated a population of 3,929,214. At that time a classification of the population was necessitated by the constitutional requirement that only three fifths of the slaves be included in the population count to be used for apportionment or representatives. It was also found desirable at this census to divide the free population into white males under 16, white males 16 and over, white females, and other free persons. The entire report of the first census is contained in a volume of 56 pages.

The third census (1810) marked the first attempt to gather industrial statistics, although the returns were not considered entirely satisfactory. In 1830, for the first time, the assistant marshals were given printed schedules—an important step toward unifying the method of reporting. The sixth census (1840) marked the first systematic attempt to collect a general body of usable statistics on the activities of the population; its defined objective was to cover such information on population, mines, agriculture, commerce, manufactures, and schools "as will exhibit a full view of the pursuits, industry, education, and resources of the country." Errors in the census reports led to a congressional investigation, and partly as a result of that investigation, the gathering of information for the seventh census (1850) was radically changed. This was the first census to list by name every inhabitant of the country. It provided also for data on age, sex, color, place of birth, marital status, and other facts about individuals.

Census-Taking Methods.—The first 12 censuses of the United States, 1790–1900, were conducted without benefit of a permanent census office, notwithstanding the fact that a cadre of professionals developed. After the 1900 census, Congress enacted the Permanent Census Act creating the Bureau of the Census on March 6, 1902. First established in the Department of the Interior, it was transferred to the Department of Commerce and Labor in 1903, and remained in the Department of Commerce after 1913 when a separate Department of Labor was formed.

The field supervisors for the first nine censuses, 1790–1870, were the marshals of the United

States judicial districts, and the enumerators were the deputy marshals. The census of 1880 marked a major improvement in the method of collecting information. From that year, the temporary field organization was discontinued on the old judicial district lines and was set up more nearly in the present manner. The number of employees was increased in an attempt to complete the enumeration in one month instead of the 10 to 20 months which had been required for previous censuses, thus making the information conform more nearly to the census date. Since 1940, the Census Bureau has maintained a nucleus field organization to conduct special surveys, and around this organization the temporarily expanded field force was built for the 1950 census.

As a result of the establishment of the Census Bureau as a permanent statistical gathering agency, the efficiency of census-taking and of the tabulation and publication of results has shown continued improvement. Notable has been the lightening of the peak load of work, coinciding with the decennial census years, by the allocation of portions of the original decennial censuses to other years; and the increase in frequency of canvasses in the fields of industry, distribution, and agriculture to provide more current statistical information.

Tabulating Equipment.—Notable also has been the improvement in census-taking techniques, the development of sampling on a scientific basis, the invention and improvement of tabulating equipment, and the application of the principles of electronics in new statistical computing machines. The year 1951 marked the completion of the construction for the Census Bureau, under supervision of the U.S. Bureau of Standards, of an electronic device, the Universal Automatic Computer, called the UNIVAC. This machine represents the first in the field of electronic computing machines for statistical use as opposed to use for the solution of complicated mathematical formulas. It was designed and constructed to meet the specific problems of the Census Bureau in recording, computing, and interpreting mass statistics at high rates of speed. The UNIVAC supplements, and eventually is expected to replace, much of the card tabulating equipment which represents the modern form of the first tabulating machines designed for the Census Bureau by Herman Hollerith and subsequently improved by E. M. LaBoiteaux and James Power.

The invention and improvement of computing and tabulating equipment has created a demand for more effective and adaptable schedules. In this field, the use of "mark-sensing" cards and procedures in Canada and Denmark is of the greatest current interest.

Special Censuses.—Since 1900, censuses in certain fields have come to be taken more frequently than decennially. The census of manufactures was taken in the United States at five-year intervals from 1900 to 1920 and at two-year intervals through 1940. After a lapse during World War II, the most recent industrial census was taken in 1948, covering operations in 1947. Since 1920, the census of agriculture has been taken every five years. The census of business, taken as part of the 1930 and 1940 decennial censuses, was repeated in 1949. Recent legislation provides that the census of business, together with the census of manufactures, a census of transportation, and the census of mineral industries recur at five-year intervals beginning in

1954. This removes the load of business and industrial censuses from the peak-year period of the population census. Other decennial censuses removed from the "0" years are the census of governments, which collects statistics of state and local governments. On the basis of legislation enacted in 1950, this census is to be taken at five-year intervals beginning with 1952. A new census of religious bodies, one of which was taken in 1936, was scheduled for 1956.

In addition to the decennial censuses, the Census Bureau compiles comprehensive statistics at annual, quarterly, and monthly intervals in the fields of employment, unemployment, manufacturing, retail and wholesale trade, exports and imports, financial statistics of states and cities, and other subjects for which current statistical needs arise.

The 1950 Census.—The 1950 census was the largest population, housing, and agricultural inventory ever undertaken by the United States. The field organization consisted of 14 area offices, each in charge of district field offices in a group of states. There were 457 district field offices established largely along congressional district lines. Under the district supervisors was a force of 8,300 crew leaders and 140,000 enumerators. These field workers traveled an estimated 25 million miles in visiting every dwelling place in the nation's 4,270 urban places and in the rural areas of the country. Final returns showed 150,697,361 inhabitants in continental United States as of April 1, 1950.

**POPULATION OF CONTINENTAL
UNITED STATES: 1790 TO 1950**

Census year	Population	Number	Percent
1790	150,697,361	19,028,086	14.5
1840	131,669,275	8,894,229	7.2
1890	122,775,046	17,064,426	16.1
1920	105,710,620	13,738,354	14.9
1910	91,972,266	15,977,691	21.0
1900	75,994,575	13,046,861	20.7
1890	62,947,714	12,791,931	25.5
1880	50,155,783	10,337,334	26.0
1870	39,818,449	8,375,128	26.6
1860	31,443,321	8,251,445	35.6
1850	23,191,876	6,122,423	35.9
1840	17,069,453	4,203,433	32.7
1830	12,866,020	3,227,567	33.5
1820	9,638,453	2,398,572	33.1
1810	7,239,881	1,931,398	36.4
1800	5,308,483	1,379,269	35.1
1790	3,929,214		

* Revised figure.

UNITED STATES BUREAU OF THE CENSUS

The Census Bureau is the agency responsible for the conduct of the major censuses and for the compilation and publication of many other reports that are of widespread use, and that can be collected or compiled with exemplary economy by the census organization.

In addition to its responsibility for the collection of basic statistical information under specific census legislation, the Census Bureau plays an important role as a statistical service agency for other branches of the federal government. During the years of preparedness for and conduct of World War II, the Census Bureau collected and tabulated statistical information for the War Production Board, the Office of Price Administration, and a number of other defense and military agencies. Under the authority given the Bureau of the Budget in the Federal Reports Act, the Census Bureau has been designated as the collecting agency in surveys designed to

provide statistical information on special subjects for other departments. With the resurgence of national defense activities following the outbreak of fighting in Korea in June 1950, the Census Bureau again was called upon to perform special statistical services for national defense agencies such as the National Production Administration, the Civilian Defense Administration, the Department of Defense, and others.

Many nongovernmental agencies also avail themselves of special services performed by the Census Bureau. Tabulations of census data in special arrangements desired by businessmen are made on an actual cost basis. The same type of service is offered governmental agencies on the local level.

Another of the more important services maintained by the Census Bureau is that of searching old population census records to provide individuals with transcripts of personal information to assist them in establishing their age, citizenship status, or other characteristics. This information is supplied only to the individual to whom it relates or his authorized representative, since all information in census records is confidential. The principal demand for personal census transcripts stems from the enactment of the Social Security Act in 1935. Since about 50 million older Americans do not have birth certificates because most states did not have birth registration systems until after the turn of the century, the importance of census records as a source of evidence regarding age for individuals reaching 65 years of age and seeking to qualify for social security benefits is obvious. Requests for personal transcripts of census records average about 100,000 per year. In one year however, during the period of World War II, more than 700,000 such requests were serviced at a time when employment on defense projects was limited to citizens. Transcripts of census records were accepted as proof of such citizenship; in most cases, such transcripts were the only official data available.

Reports to the Census Bureau are made for statistical purposes only. No information about any individual person or form can be obtained from any census publication. All data are collected by the bureau for statistical purposes so that the American people can have an accurate picture of the economic, social, and political condition of the nation.

Statistical Services of Other Federal Agencies.—The Census Bureau is by no means the only agency of the federal government which collects data and issues reports of a statistical nature. Statistical publications of basic importance in specialized subject fields are issued by many other government departments and bureaus. To name a few, current estimates of crop acreages and production, and many other related data, are produced by the Bureau of Agricultural Economics of the Department of Agriculture. The Bureau of Labor Statistics of the Department of Labor issues figures on prices and compiles many other statistics concerning, or of interest to, labor. Further, various administrative agencies, such as the Social Security Administration and the Civil Service Commission, publish statistical reports. The Federal Power Commission provides current statistics in its field, and the Interstate Commerce Commission performs a similar service with respect to railways. Finally, the entire statistical program of the

federal government is reviewed and coordinated by the Division of Statistical Standards of the Bureau of the Budget.

Census Bureau Publications.—Reports of the 17th decennial census are embodied in a series of bulletins for each state, a series of bulletins on selected subjects, and a series of United States summary bulletins. Final bound volumes, usually a separate one for each state, and one for the United States, consolidate geographical area bulletins under single covers. After each decennial census, the Census Bureau publishes a *Catalog of Decennial Census Publications*. It also publishes quarterly, with an annual consolidation, a *Catalog and Subject Guide to Census Publications*, listing and describing the contents of all census reports currently published.

The *County and City Data Book, 1949* brings together 101 items of information for each state, each county, and each standard metropolitan area, and 92 items for each of about 400 cities having 25,000 or more inhabitants in 1940. Broad subject fields covered include the 1948 census of business, 1947 census of manufactures, 1945 census of agriculture, and (preliminary) 1950 census of population.

In addition to these general publications, there are available interim and final reports of the various recent censuses and surveys in the fields of manufactures, retail and wholesale distribution and service trades, agriculture, foreign commerce, state and local government finances and public employment, current population statistics including data on employment and unemployment, and other

the *Labor Force*, the *Current Population Reports*, and *International Population Reports*, the last-named two series being issued at frequent but unspecified intervals.

Most of the reports of the Census Bureau are available in public libraries and in field offices of the Department of Commerce. Copies of these reports may be purchased from the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C., or from Commerce Department field offices. Requests for information on obtaining copies of unpriced census publications should be addressed to the director, Bureau of the Census, at Washington.

ROY V. PEEL,

Director, Bureau of the Census.

CENT, a United States coin and money of account, the 1-100 of a dollar. The convenience of decimal computation has caused in various countries the division of the monetary unit into hundredths, with names derived from Latin *centum* or its adjectives; as the French franc into centimes, the Dutch guilder into cents, the Italian lira into centesimos, the Spanish-American dollar into centavos, etc. Thomas Jefferson regularly used cent to mean the hundredth of any unit of measurement; but in its first suggestion for our coinage it meant 100. The inconvenience of the English system being felt, Congress in 1781 instructed Robert Morris to devise a system of national coinage; and he proposed a unit of $\frac{1}{4}$ grain of silver (or 1-1440 of a Spanish dollar, familiar in the colonies), of which 100 were to make a cent (about 7c. of ours), 500 a quint (34.7c.), and 10,000 a mark (\$6.94). Jefferson proposed instead the dollar as a unit, the smallest coin to be of copper and 1-200 of it (that is, the old English farthing, our half-cent); this was adopted July 6, 1785. But on Aug. 8, 1786, an act was passed, still modeled by Jefferson, to coin a cent, of which 100 were to weigh $2\frac{1}{4}$ pounds avoird-

pois (157.5 grains each), and be equal to a dollar, and a half-cent proportionate. This was the first use of the name in our coinage, and doubtless represents Jefferson's "hundredth." The "cents" prior to this have not that name on them, and are really English halfpence. The difficulty of displacing a popular name is shown by that of "penny," which still clings tenaciously though absurdly to our cent, only half its value. Congress in 1787 established a mint in New Haven, and for years coined there the "Fugio" or "Franklin" cents, familiar to collectors. But from 1785 to 1788 several states coined copper cents on their own account. Vermont (not yet admitted) began in June 1785; Connecticut in October 1785; Massachusetts late in 1786 (real half-cents); New York, 1786; New Hampshire (coppers 15 to the shilling). Under

the constitution the first coinage act was passed April 2, 1792, and raised the weight of the cent to 11.52 grains, but on Jan. 14, 1793, it was re-

duced to 10.89 grains, and the half-cent always being proportional. The first coinage under the new act was in 1793. This old-fashioned "copper" remained unchanged except in pattern till 1857, and its forms from 1793 to 1857 are of seven types: (1) 1793, chain or link around the word "cent"; (2) 1793, wreath in place of chain; (3) 1793-1796, liberty cap on pike over left shoulder of "Liberty"; (4) 1796-1807, "Liberty" with draped bust; (5) 1808-1814, filleted head with 13 stars. (6) 1816-1839, plain coronet with coiled hair.

Those of 1793, 1799, and 1804 are very rare, as are also the copper cent of 1856 and the half-cents of 1793, 1831, 1840 to 1848 and 1852. On March 3, 1851, a 3-cent piece was authorized, of $12\frac{1}{2}$ grains, 75 per cent silver, 25 copper, legal tender to 30 cents; on March 3, 1853, it was raised to .900 fine, but reduced to 11.52 grains, $\frac{3}{50}$ of the half-dollar. On Feb. 21, 1857, the half-cent was abolished and the old cent replaced by a smaller new one, of 72 grains, .88 copper and .12 nickel. On April 22, 1864 this was supplanted by a bronze cent, 48 grains (the present one), .95 copper and .05 tin and zinc, legal tender to 10 cents; and a bronze 2-cent piece, twice its weight and legal tender. On March 3, 1865 a 3-cent piece was authorized, $\frac{3}{4}$ copper and $\frac{1}{4}$ nickel, 30 grains, legal tender to 60 cents; but the ones and twos were made legal tender to only four cents. On May 16, 1866 a 5-cent piece (the nickel) was authorized, same material as the 3, 77.16 grains, legal tender to \$1. On Feb. 12, 1873, all cents and their multiples were discarded except the 1, 3 and 5, as above, each to be legal tender to 25 cents; and on Sept. 26, 1890, the 3-cent piece was discarded. See also COINAGE OF THE UNITED STATES; NUMISMATICS.

CENT, a name given under the old Germanic constitution to a small portion of territory. Each province or district was subdivided into so many cents and was placed under the special jurisdiction of an overseer or centenarius. The name corresponds with hundred as in English territorial division.

CENT-GARDES, *san-gerd*, (Fr. "The Hundred Guardsmen"), a body-guard acting in the service of the French king during several centuries. See GUARDS.

CENT JOURS. See HUNDRED DAYS.

CENT NOUVELLES NOUVELLES, *Les, sãn nōō-věi'*, a collection of facetious tales, first published at Paris in 1486 by Antoine Vérard from a manuscript written in 1456. They were told at the table of the dauphin, afterward Louis XI, in the castle of Genappe (Belgium) during his exile. The arrangement in their present form has been attributed to Louis himself and to Antoine de la Salle. The historical importance of the collection arises from its details regarding manners and customs of the 15th century that can be found nowhere else. Among the narrators are obscure and untitled men, probably domestics of the duke of Burgundy, who figure side by side with some of the greatest names in French history. The collection was edited by Thomas Wright in two volumes (Paris 1858), and a smaller edition was published by Pierre Champion (Paris 1928).

CENTAUREA, *sãn-tō-rě'a* (including BACHELOR'S BUTTON or CORNFLOWER, DUSTY MILLER, KNAPWEED, STAR THISTLE, SWEET SULTAN, RAGGED ROBIN, RAGGED SAILOR), a genus of annual, biennial, or perennial herbs of the Compositae (Composite) family, with alternate, or all basal, entire to pinnatifid leaves, and solitary to numerous, small to large, heads of flowers. Many of the species are widely used in ornamental gardening.

The following are among the popular garden sorts: *C. Cyanus*, the bachelor's button or cornflower, common in Mediterranean grain fields and frequently established in America, whose blue flowers yield a blue dye; *C. Cineraria*, the dusty miller, from southern Italy and Sicily, with white hairy leaves; *C. moschata*, sweet sultan, from the Orient, widely grown for its large, fragrant flower heads; *C. montana*, mountain bluet, which originally had blue flowers, but developed various other tints under cultivation.

All the species are easily grown from seed and thrive in any good garden soil. *C. solstitialis*, the yellow star thistle, blooms from July to September and offers bees a continuous flow of honey. The Napa thistle or tocalote, *C. melitensis*, blooms earlier and yields a light amber honey in May and June, but is a pernicious weed in cultivated fields and is widely distributed in California. The Russian knapweed, *C. repens* (*C. picris*), is another pest which annoys the farmer while offering a harvest to the beekeeper. The virgate star thistle, *C. virgata*, variety *squarrosa*, appears as a pest in sheep pastures in California, where sheep and cattle will not eat it.

Consult Pellett, F. C., *American Bee Journal*, vol. 91, No. 103 (Hamilton, Ill., 1951); Bellue, M. K., "Virgate Star Thistle, *Centaurea Virgate*, var. *Squarrosa*," State of California Dept. of Agriculture, *Bulletin*, 1952, vol. 11, No. 2, pp. 61-63 (Sacramento 1952); Gleason, H. A., ed., *The New Britton and Brown Illustrated Flora*, vol. 3, p. 513 (New York 1952).

ARTHUR GRAVES.

CENTAURS, *sãn'tōrz*, in Greek mythology, a fabulous race dwelling originally in Thessaly and later in the Peloponnese. According to one of many fables, they sprang from the union of Ixion and a cloud. They are said to have been half horse and half men, and the fable is explained by the surprise of the Greeks on encountering the wild horsemen of northern tribes. Mythology relates the combats of centaurs with

Hercules, Theseus, and Pirithous. The last, at the head of the Lapiths, another Thessalian people and their hereditary enemies, entirely defeated the centaurs, killed many, and drove them from Thessaly. See also CHIRON; DEIANIRA; HERCULES; NESSUS.

CENTAURUS, *sãn-tō'rūs*, or **THE CENTAUR**, a southern constellation, only a small part of which is visible in northern latitudes. It received its name in antiquity from its stellar resemblance to the mythical centaurs (q.v.). The constellation is large and contains many bright stars, including Alpha and Beta, both of the first magnitude. The former, the third brightest star known, is the nearest bright star to Earth—its distance being only slightly greater than that of a small companion known as Proxima Centauri. Alpha itself has a parallax of 0.75, which gives a distance of $4\frac{1}{3}$ light years. It is also a famous double star, its period being 80.1 years, and the

The constellation Centaurus.

masses of its components being 1.10 and 0.94 that of the Sun. The brighter component has the same spectral class (GO) as the Sun, which it resembles in every respect.

The constellation contains the globular cluster known as Omega Centauri, visible to the naked eye as a faint star. It is composed of thousands of stars and is probably our nearest neighbor among such clusters, being about 21,000 light years distance. If our Sun should be set in this cluster, it would be just at the extreme limit of the 100-inch telescope; hence most of the 6,000 stars so far seen therein must be considerably more luminous.

CENTAURY, *sãn'tō-rĩ*, common name for a genus of plants, *Centaureum* (sometimes known also as *Erythraea*), belonging to the family Gentianaceae. A few species are cultivated in rock gardens, usually as annuals, for their attractive flowers, commonly in shades of pink. The species are widely distributed: those in cultivation include *C. Massonii* from the Azores, *C. conferta* from Europe, *C. Beyrichii* from the southern United States, and *C. venustum* from California. Other species grow wild in the United States, especially in the West. A European centaur has been used medicinally, chiefly in home remedies, as a bitter tonic, for dyspepsia and other ailments. *Sabatia stellaris*, a related plant, is called American centaur by materia medica because of its similar use, but it is perhaps better known as the marsh pink. Another genus of plants, *Centaurea* (q.v.), of which the cornflower or bache-

lor's button and the sweet sultan are members, should not be confused with *Centaurium*.
N. HIGINBOTHAM.

CENTAVO, sên-tă'vô, a minor coin, a hundredth part of the monetary unit (usually the peso) of Mexico, other Latin American countries, and the Philippines. The Portuguese centavo is the hundredth part of an escudo.

CENTENARY, sên'tê-nê-î (from Lat. *centenarius*), a period or age of 100 years; also the commemoration of an event, such as a great man's birth or the founding of a city or nation, which occurred 100 years previously. The synonym "centennial" is often used; thus the Centennial Exhibition commemorates the birth of the United States, and the "Centennial State" is a nickname for Colorado, which was admitted to the Union in 1876.

CENTENARY COLLEGE, Shreveport, La., a state institution originally founded in Jackson, La., in 1825. This school, which at first was called the College of Louisiana, was discontinued in 1845, and its buildings and charter were promptly acquired by Centenary College, which had been established in 1839 by the Methodists of Mississippi in celebration of the one hundredth anniversary of the founding of their denomination.

Before the Civil War it was one of the leading colleges of the South, but the four years of war (1861-1865) and the ensuing reconstruction era made survival difficult. In 1908 the school, which for some years had belonged to the Methodist Conference of Louisiana, was moved from Jackson to Shreveport, a thriving commercial city in the northwestern corner of the state. Its annual enrollment exceeds 1,000.

The academic courses are administered by the dean of the college through three general divisions of study—humanities, natural sciences, social sciences—and the departments which they include. The college also conducts a school of music on the campus.

The institution, which is coeducational, grants the bachelor's degree in arts, science, and music, and provides courses in many fields for students who later enroll in professional schools.

ARTHUR MARVIN SHAW.

CENTENNIAL STATE, a popular name given to the State of Colorado on account of its admission to the Union in 1876, the one hundredth year of the independence of the United States.

CENTENO, thên-tă'nô, Diego, Spanish soldier: b. Ciudad-Rodrigo, León, Spain, 1505; d. La Plata, Peru, 1549. As a member of Pedro de Alvarado's expedition to Peru, he won renown. In 1544 he sided with the viceroy, Vela Blasco Nufiez, against Gonzalo Pizarro, brother of the conqueror Francisco, upholding the royalist cause in the conflicts for power. He was defeated by Gen. Francisco de Carvajal and fled to the Pacific. A year later he again raised the royal standard, combining with Pizarro's chief in La Plata, and met Carvajal in a great battle in the Province of Charcas, where he was defeated. This was not a final defeat, for Pedro de la Gasca, envoy of Charles V of Spain, made him governor of La Plata, and the king ennobled him.

CENTENO VALLENILLA, sân-tă'nô vâ-yâ-nê'yâ, Pedro, Venezuelan diplomat and artist: b. Barcelona, Venezuela, June 13, 1904. After obtaining a degree in law at the University of Caracas in 1923, he served for four years as attaché of the Venezuelan legation in Rome, and from 1927 for over a decade as secretary of his nation's legation to the Holy See. An accomplished painter, he exhibited in several Italian expositions, including the Bienale Romana in 1924 and the Amatori e Culturi d'Arte (Rome 1926). His work was shown also in several personal exhibits in Caracas, Paris, and Rome. Among his notable paintings are *Bolívar en Roma*, *Impressions de Grèce*, *Mélancolie indienne*, *Gaïn et Abel*, *Muchacho caribe*, and *Netzahualcoyotl*.

CENTER, city, Texas, seat of Shelby County. At an altitude of 345 feet, it is 55 miles south of Marshall on the Gulf, Colorado and Santa Fe Railway and is served by national roads. It has fine old houses of the period of the Republic of Texas. Its industries include lumber, broom, and cotton-gin manufacture, and mattresses. In 1866, when it was decided that a county seat should be as nearly in the center of a county as possible, it was chosen for the honor. It was incorporated in 1903 and is governed by a mayor and council. Pop. (1950) 4,323.

CENTER, The, a political party organized in Germany in the 19th century as Roman Catholic opposition to governmental restrictions; later, a party expressing strong Catholic sentiments with a strange mixture of antiauthoritarianism and zeal for social reform. Its adherents cut across social and economic lines. Its appeals were so diverse that it received the appellation Center, or *Zentrum*. During the years of the Weimar Republic (1919-1933) it furnished several prime ministers and was always represented in the cabinet. Its strength at the polls remained about one seventh of the total vote. In Bavaria there was a separate and a stronger wing of the party than in other parts of Germany.

When Hitler was in power (1933-1945), all competing parties were eliminated. After World War II the party was revived and, with its sharp denunciation of communism, drew some Protestant support. Under the name of the Christian Democratic Union (and in Bavaria the Christian Social Union) it became the dominant political force in the West German Republic, with Konrad Adenauer as chancellor.

Catholic parties in Italy and other Continental countries have been referred to as The Center, with programs resembling those of the German *Zentrum*. Since World War II, Center parties have been stronger than formerly.

SPENCER D. ALBRIGHT,
Department of History and Political Science, University of Richmond.

CENTER OF BUOYANCY. The center of buoyancy of a floating body is that point within its boundaries corresponding to the center of gravity of the volume of water or other fluid which is displaced. It is customary to regard buoyancy as a force acting upward and opposed to gravity. This is not in accordance with fact, for all the phenomena of floating in water, air, or other fluids are due entirely to the attraction of gravity, which acts constantly downward. (See HYDROSTATICS.) When a body floats in water, it

sinks into the water and toward the center of the earth only to the extent where the earth's attraction for the body and its attraction for the volume of displaced water are equal at that level. And as the weight of a body is the measure of the earth's attraction for it we say a floating body displaces its own weight of water. A floating body will therefore sink into water only to a point where the water beneath it is attracted toward the earth's center more forcibly than is the floating body. The same phenomena may be observed in the case of a balloon. The balloon filled with a gas that is lighter than air at the sea level will rise to a position where the earth's attraction for the balloon and its attraction for the volume of air displaced by the balloon are exactly equal. The center of buoyancy of the balloon is the center of gravity of the body of air displaced by the balloon.

When the center of gravity of a floating body is below its center of buoyancy (equivalent to its point of support—see **EQUILIBRIUM**), the body will float in stable equilibrium. When the center of gravity is above the center of buoyancy the equilibrium is unstable, and the body is liable to roll over in the water into such a position that its center of gravity is below its center of buoyancy. The same observations hold good as to bodies floating in air. A body which will float in unstable equilibrium in water would probably be in unstable equilibrium in mercury, the volume of mercury displaced having a much higher center of gravity than the displaced water, and therefore lifting the center of gravity of the floating body far above its center of buoyancy.

CENTER OF GRAVITY, or **CENTER OF INERTIA**, a point in a body, or in a system of bodies, which in modern works on mechanics is usually and preferably called the "center of mass." It is that point such that the vector sum (or integral) of the moments of the particles of the body with respect to it is zero. That is, if suspended by the center of mass or gravity the system will be in equilibrium in any position. See also **MASS**; **MECHANICS**.

CENTER OF OSCILLATION, or **CENTER OF PERCUSSION**, that point of a pendulum at which its entire mass may be considered as concentrated, for the purpose of determining its time of oscillation. The pendulum may be suspended by an axis parallel to its original axis and passing through the center of oscillation without altering its period.

CENTER OF POPULATION, the center of gravity of the population of a country,

Years Census	North latitude	West longitude
1790	39° 16.5'	76° 11.2'
1800	39° 16.1'	76° 56.5'
1810	39° 11.5'	77° 37.2'
1820	39° 5.7'	78° 33.0'
1830	38° 57.9'	79° 16.9'
1840	39° 2.0'	80° 18.0'
1850	38° 59.0'	81° 19.0'
1860	39° 0.4'	82° 48.8'
1870	39° 12.0'	83° 35.7'
1880	39° 4.1'	84° 30.7'
1890	39° 11.9'	85° 32.9'
1900	39° 9' 36"	85° 49' 54"
1910	39° 10' 12"	86° 32' 20"
1920	39° 10' 21"	86° 43' 15"
1930	39° 8' 45"	87° 8' 6"
1940	38° 56' 54"	87° 22' 35"

each individual being assumed to have the same weight.

The center of population in the United States has moved in a westward direction during the last 110 years along the parallel of 39° latitude, in 1930 reaching 2.9 miles northeast of Linton, Green County, Indiana. The foregoing table shows the centers by decades since 1790. See also **CENTROGRAPHY**.

CENTERBOARD, a contrivance used in a yacht or shallow, keelless or flat-bottomed vessel, to counteract the tendency to make leeway and to enable the craft to stand up under press of sail. It consists generally of a quadrangular wooden or iron plate which is bolted or hinged by its lower forward corner into a trunk or casing which fits, watertight, over a fore-and-aft slot in the vessel's bottom, about midway of her length and fitted so that it may be hauled inside the trunk. See also **YACHTS** AND **YACHTING**.

CENTERING, or **CENTRING**, the framing of timber by which the arch of a bridge or other arched structure is supported during its erection.

CENTERVILLE, Iowa, city in Appanoose County, altitude 1,013 feet, on the Rock Island and Burlington railroads, 70 miles south of Des Moines. Manufactures include bottling works, buttons, brick and tile, ice, steel culverts, castings, and soy-bean products. Centerville has a mayor and council government. Pop. (1940) 8,413; (1950) 7,625.

CENTIGRADE SCALE. See **THERMOMETER**.

CENTIMETER-GRAMME-SECOND or **CENTIMETER-GRAM-SECOND SYSTEM**. See **UNITS OF MEASUREMENT**.

CENTIPEDE, or **CENTIPED**, one of those myriapods (*Chilopoda*) with long, many-jointed, flattened bodies, each segment bearing only a single pair of appendages, which take the form of legs behind the head. The mouth-parts, besides a pair of jaws (mandibles), consist of two pairs of maxillae, those of each pair being fused together in the middle. The first pair of legs are fused at their base, and form the poison-fangs, the poison-gland being situated in the base, and the poison oozing out of an orifice at the end of the leg. The single oviduct and corresponding male duct open at the end of the body in the penultimate segment. The centipedes (*Scolopendra*) are mostly confined to the tropics, a small species extending as far north as North Carolina. Those of the West Indies and the tropics in general are eight to nine inches in length, one species, however, attaining the length of 18 inches. Their bite is dangerous, quite as much so as the sting of the scorpion. They are ferocious when attacked or seized, biting energetically. In the Northern States the centipedes are represented by the species of *Lithobius* (*L. americanus*), which are wrongly called "earwigs," and live under stones, under the bark of fallen trees, etc. They prey on insects and worms. They have been observed to attack earthworms, grappling with them for several hours and, after killing them, sucking their blood. Very long, slender forms are *Geophilus* and its allies. The body is

composed of from 19 to nearly 200 segments, each bearing a pair of legs. They are eyeless, and live buried in the sand, coming to the surface under stones.

The centipedes are hatched with numerous segments, and corresponding legs. Wood states that the female of a centipede (*Scolopocryptops scarpinosa*) guards her young by lying on her side, and then coiling her body, passes them along by a quick action of her feet, thus arranging them satisfactorily to herself. He also describes the manner of molting in this species.

The chilopods are more nearly related to the insects than are the millipedes. They are a less ancient group. No true *Chilopoda* are known to exist in rocks older than the Middle Tertiary period, species of *Cermatia*, *Scolopendra*, *Lithobius* and *Geophilus*, having been detected in amber and the gypsum beds of Aix, Provence, France, of Oligocene age. (See CHILOPODA.)

Eastman 1913); Brade-Birks, S. G., and H. K., "Luminous Chilopoda," in *Annals and Magazine of Natural History* (1920); Chamberlin, R. V., *New Genera and Species of American Lithobid Centipeds* (Logan, Utah 1941); id., *On Mexican Centipeds* (1943).

CENTLIVRE, sɛnt-liv'ɛr, **Susannah Freeman**, English actress and dramatist: b. Ireland about 1667; d. London, Dec. 1, 1723. When very young she married a nephew of Sir Stephen Fox. Becoming a widow within a year she took for a second husband an officer of the army of the name of Carrol, who was killed in a duel the second year of their wedlock. This event in her singular career reduced her to considerable distress, and led her to attempt dramatic composition. Her first production was a tragedy entitled *The Perjured Husband*, performed in 1700. This was followed by several comedies, chiefly translations from the French, which exhibited the vivacity that distinguishes her literary character, and met with some temporary success. She also tried the stage as an actress on the provincial boards, and by that means attracted the attention of her third and last husband, Joseph Centlivre, Queen Anne's head cook, whom she married in 1706. She still continued writing for the stage, and produced several more comedies. Some of these remain stock pieces, of which number are *The Busy Body*; *The Wonder* (1709); and *A Bold Stroke for a Wife! A Woman Keeps a Secret* (1714). They are diverting from the variety of incident and the liveliness of the characters, but want the accompaniments of adequate language and forcible delineation. They partook of the license of the age. Mrs. Centlivre enjoyed the friendship of Sir Richard Steele, George Farquhar, Nicholas Rowe and other wits of the day. Having, however, offended Alexander Pope, she obtained a place in the *Dunciad*, but is introduced by no means characteristically. An edition of her works with a biography appended appeared in 1761 and was reprinted in 1872.

CENTNER, a German weight, in common use on the continent of Europe, which is nearly the equivalent of the British hundredweight. It formerly varied in the different German states, but since the introduction of the metric system of weights and measures into the German Reich, Jan. 1, 1872, the value of the centner has been

fixed at 50 kilograms, or 100 German pounds equivalent to 110.23 pounds avoirdupois. In Austria it was equal to 110½ pounds, and in Sweden to 112.06 pounds.

CENTO, chɛn'tō, Italy, city 13 miles north of Bologna, on the eastern bank of the canal or Cento and near the river Reno. It is surrounded by a rampart and ditch and contains several churches, convents and a cathedral. The celebrated painter, Giovanni F. Barbieri, commonly called Guercino, was born here about 1590. A statue of him stands in front of the Palazzo Governativo. The gates of the ancient town have been preserved. It has a hemp and rice market. Pop. town 5,677; commune 22,371.

CENTO, sɛn'tō (Latin, "patchwork"), originally a cloak made of patches; hence, as Lessing observes, the dress of Harlequin is called in Apulcius *mimi centuculus*. The term has been transferred to such poems as have been formed out of verses taken from other poems. It was a particular art to combine passages of different authors on different subjects in this manner so as to form a regular whole. Thus there were in early times Virgilian centos (*centones virgiliani*) in which most of the verses were taken from Virgil; for instance, the *Cento Nuptialis* of Ausonius, and centos from the verses of Homer (*Homeric centones*). It was a favorite pastime in the Middle Ages.

Consult Delepierre, *Tableau de la littérature du cento* (London 1874-75).

CENTRAL AFRICA PROTECTORATE. See NYASALAND PROTECTORATE.

CENTRAL AMERICA, the geographical name applied to the narrow strip of land connecting North America and South America. Traditionally, Central America begins on the north at the boundary between Mexico, on the one hand, and Guatemala and British Honduras, on the other. The southern limit is the boundary between Panamá and Colombia (South America). The southward-tapering strip of land, thus delimited, extends roughly from northwest to southeast with an extremely irregular outline, and a width varying from 30 miles in some parts of Panamá to 350 miles near the Honduras-Nicaragua boundary. Central America includes an area of 228,578 square miles, and has an estimated population (1950) of 10,028,000.

Political Divisions.—The territory of Central America is divided among six republics and one British colony. From north to south, these political divisions, with area and population (1950 est.), are:

Political division	Area in sq. mi.	Population
British Honduras	8,688	70,000
Guatemala	42,044	3,717,000
Honduras	59,160	1,326,000
El Salvador	13,176	2,100,000
Nicaragua	57,143	1,173,000
Costa Rica	19,238	825,000
Panamá (including Canal Zone)	29,129	817,000
Central America	228,578	10,028,000

Terrain and Structure.—Central America is all too commonly considered to be a simple, continuous mountain range linking the mountains of

10°F., and frequently less than 5°F. At Greytown (San Juan del Norte), on the coast in southern Nicaragua, for example, a short record shows December and January to average 77.5°F., whereas April and May average 80.8°F. There is much greater difference between day and night, often as much as 15°F. Yet, seldom do temperatures reach the high 90's. Accompanying the uniformly high temperatures are large amounts of rain with no pronounced period of dryness. The coast is exposed throughout the year to the trade winds from off the warm ocean to the east and, thus, along most of its length, the Caribbean coast receives over 80 inches of rainfall during the year. The largest amount falls on the lowland along the border between Nicaragua and Costa Rica. The short Greytown record shows an average of 259 inches per year, with March the driest month (6.5 inches). At all times, relative humidity is high; days without some rain are infrequent.

Most of the Pacific coastal zone has like temperatures, but rainfall differs markedly in amount and in distribution through the year. The amount is seldom in excess of 80 inches per year, and is much more commonly between 50 and 60 inches. Furthermore, the rainfall is distinctly seasonal. Slight amounts fall from October through March, when the winds are dominantly offshore. The greater part of the year's total is concentrated in the period from March through September, when southerly and southwesterly winds from off the warm Pacific blow onshore.

Throughout the highlands, there is less climatic uniformity. Temperatures are generally lower with increased elevation, and there is a tendency over the greater part of the highlands toward seasonal distribution of rain, similar to that along the Pacific coast. Where the slopes are oriented so as to intercept the moist winds from off the Caribbean, however, amounts are large, and distribution through the year is much more even. Guatemala City, at an elevation of 4,900 feet, offers a fairly representative sample for the highland as a whole. There, the warmest month, May, averages 69°F., and the coolest month, December, averages 61°F.; the rainfall averages 52 inches per year; and each month, from November through March, has less than one inch of rain.

The differences induced by altitude are sufficiently well marked so that there can be recognized rather clearly defined zones at different altitudes. These are known, in order, from lowest to highest, as the *tierra caliente*, the *tierra templada*, and the *tierra fría*. The climatic differences are reflected particularly in changes in natural vegetation and crops. The limits of each zone are generally higher on the Caribbean than on the Pacific side of the isthmus, primarily because of the greater rainfall on that side. The height limits, likewise, decrease northwards. In Costa Rica, L. Waibel states the height limits to be as follows: *tierra caliente*—sea level to 2,100 feet, on the Caribbean side, and to 1,475 feet, on the Pacific side; *tierra templada*—2,100 to 5,900 feet, on the Caribbean side, and 1,475 to 4,900 feet, on the Pacific side; and *tierra fría*—above 5,900 feet, on the Caribbean side, and above 4,900 feet, on the Pacific side.

Hydrography.—There are no long rivers in Central America. Likewise, none of the streams is navigable for commercial vessels. The divide between the Caribbean and the Pacific drainages

lies everywhere close to the Pacific coast. Streams flowing into the Caribbean vary less in volume than those flowing into the Pacific because of the large amount of rainfall, and its more regular distribution through the year, throughout their basins. Destructive local floods are common along the rivers flowing toward the Pacific during the rainy season; these same streams are practically without water during the dry season. Only a few lakes deserve mention. In one of the intermont basins of highland Guatemala lies the touristically famous Lake Atitlán, and in the swampy lowland of eastern Guatemala lies Lake Izabel. Lakes Managua and Nicaragua complete the list. South of the Nicaraguan Lowland lakes are conspicuously absent.

Natural Vegetation.—The hot, wet lowlands of Central America bear a dense cover of tropical forest. Broadleaf evergreen trees of many species, including cabinet woods like mahogany and rosewood, spread over much of the *tierra caliente*, particularly along the wetter Caribbean coast. Where the rainfall is less, or where there is a pronounced dry period during the year, the forest is lighter, and is deciduous. In a few relatively dry areas, as along the Pacific coast of Guatemala, or in the eastern lowland of El Salvador, the forest gives way to tropical grass (savanna). Increased elevation, with the attendant lowering of temperatures, brings about a change in the forest type. Trees like the oak replace the tropical species. And, above them, in the highlands of Guatemala, Honduras, and northern Nicaragua, there are forests of pine. At the highest elevations, usually above 10,000 feet, mountain grass replaces the forest.

Much of the original forest in the highlands has been removed, largely to make way for agriculture. Similarly, in the lowlands, where plantations have developed, as on the coast of eastern Guatemala and northern Honduras, the original cover has been largely destroyed.

Mineral Resources.—Central America is significantly poor in most mineral resources. Silver has been mined at Huehuetenango, in the Guatemalan highland, since the latter part of the sixteenth century. Small amounts of gold, silver, mercury, and lead are produced in northwestern El Salvador. Silver and gold, in small amount are produced in Honduras, particularly near Tegucigalpa, and along the Nicaraguan border. Gold is dredged from several Nicaraguan rivers. In no instance is the amount significant in terms of total world production.

Population.—Central America's ten million people are racially diverse. Further, the proportion of each element in the population varies from country to country. For the whole area, the Indian and mestizo (mixed Indian and European) elements are both far superior in numbers to any of the other groups. People of unmixed European stock form the third most numerous group, and Negroes, together with Negro mixtures, the smallest. Forty-five per cent of the total population is mestizo; 41 per cent, Indian; 10 per cent European; and 4 per cent, Negro. These proportions do not hold, however, when each country is considered separately. The population of Guatemala is dominantly (67 per cent) unmixed Indian; that of Nicaragua is dominantly (77 per cent) mestizo; and in Costa Rica, the unmixed European element is the largest (48 per cent). The largest Negro element (48 per cent) is in British Honduras. This racial diversity is in part

Photographs from Ewing Galloway

a reflection of the early population distribution. The Old Maya Empire developed in lowland Guatemala and adjacent Mexico. It was there that the largest Indian population existed at the time of European conquest. In contrast, Negroes were the last group to be introduced. They were brought to the coastal lowlands of British Honduras, Honduras, and Nicaragua, primarily to supply plantation labor requirements. The main center of unmixed Indian population is the Guatemalan highland; most of the population there is still of Mayan origin. In eastern Honduras, and in eastern Nicaragua, back from the coast, the population is also unmixed Indian, but of other stocks than the Mayan. A third Indian concentration is found in eastern Panamá. Negroes and Negro admixtures are still most numerous in the coastal areas aforementioned. The only center of unmixed European blood is the San José section of highland Costa Rica. Elsewhere, throughout Central America, mestizos form the bulk of the population.

The distribution of people throughout Central America is very uneven. Within each country, there are both densely settled and nearly empty lands. Likewise, each country has distinct settlement nuclei. The population of Guatemala, for example, is concentrated in the southern highland third of the country, while the northern lowland half is almost devoid of population. The highland core of El Salvador is densely peopled in contrast to the nearly empty lowlands. Within Honduras, there is a dense fringe along the northern coastal lowland, and there are dense clusters in the intermont basins along the El Salvador boundary. In Nicaragua, the concentrations are in the western part of the Nicaraguan Lowland, and along parts of the Caribbean coast. Costa Rica's population is remarkably tightly packed in the San José section. In Panamá, sections of both the Pacific and Caribbean coastal lowlands and the Canal Zone are densely peopled, while most of the mountainous interior is empty.

Economic Life.—Agriculture dominates the life of the greater part of the population of Central America. It ranges in type from the primitive migratory, or shifting, cultivation of cleared forest patches, to highly specialized commercial plantation agriculture. Throughout the whole area, three crops stand out as the keys to the agricultural scene: maize, coffee, and bananas. The subsistence farming of most of the population rests upon the cultivation of maize. Combined with this crop are a variety of secondaries like rice, beans, and potatoes. Cotton, henequen, sugar cane, and tobacco are frequently grown, largely for local use, but occasionally in amounts of a commercial size. Cacao has its place as well.

On the commercial scale, coffee and bananas outrank all other crops. Coffee is the highland crop, and bananas, the lowland crop. For the most part, coffee occupies hill land, often so steeply sloping as to be unsuited for other than tree crops. Both garden and plantation forms exist, and the cultivation is in the hands of the native peoples, for the greater part. In the lowlands, particularly the Caribbean lowlands of northern Honduras, eastern Guatemala, and Costa Rica, foreign controlled banana plantations have expanded to include large acreages of formerly wet jungle land. Most of these plantations are under the control of the United Fruit Company.

The list of other tropical products includes indigo, abaca, palm oil, and coconuts. All are

of local rather than of area-wide significance.

In addition to agriculture, there is appreciable attention, particularly in British Honduras and in Guatemala, to forest products, from cabinet woods to chicle. Likewise, mining makes a real contribution, especially in Nicaragua. The grazing of cattle, in the savannas of eastern El Salvador and in the mountain grasslands of Honduras, adds slightly to the total economy.

In Panamá, the dominant role of agriculture is overshadowed by the strong influence of the Canal Zone. In this 10-mile-wide strip of land and water, over which the United States has essentially complete control, a large portion of the total Panamanian national income is received by a relatively small part of the total Panamanian population for services related to the presence of the canal. This situation is reflected in a per capita income for Panamá higher than that in any other Central American state.

So far as foreign trade is concerned, the role of the United States is the dominating one. Between 75 and 90 per cent of all exports, from each of the republics, are destined for the United States market, while 65 to 75 per cent of all imports come from the United States. The small trade of British Honduras is more closely linked with that of other British possessions.

Professor of Geography, Miami University;
Coauthor of "Introduction to Geography."

CENTRAL AMERICA, Diplomatic Relations with.—The earlier general interest of the United States in Latin America was first attracted to a larger consideration of the problems relating to Central America under Monroe's administration, which in 1818 had an opportunity to consider suggestions for establishing the southern limit of the United States at the Isthmus of Panama, in 1819 completed the establishment of the United States as a Gulf power by the acquisition of Florida, in 1822 recognized the extinguishment of direct Spanish interests in Mexico, and in 1823 received from Salvador diplomatic overtures for annexation or a protectorate—overtures which were later withdrawn by the disappearance of the danger of forced annexation to Mexico.

In 1823, with consent of Mexico the five Central American states were united into a national federation which subsequently adopted a constitution on the model of that of the United States and borrowed the code of Louisiana.

Central American commissioners presented their credentials at Washington Sept. 10, 1823. In 1824, Secretary Adams instructed Thomas N. Mann to visit Guatemala to obtain statistics and political information; and in 1825 the American government recognized the Federation of Central America, which in the same year was also recognized by Great Britain and the Netherlands. The first American diplomatic agent to the Federation, John Williams, was commissioned on Dec. 29, 1825; and the last American representative to the Federation, appointed in 1841, left his post in March 1842. The last Federation

representative at Washington took his leave March 16, 1828.

On Dec. 5, 1825, the United States negotiated with the Federation a treaty of commerce which expired by its own limitations in 1837 and was never renewed. In April 1825, the American government received from Canaz, the representative of the Federation, a proposal of co-operation in promoting the opening of a canal through Nicaragua, and, in 1826, through the influence of Mr. Williams, the Central American government contracted with A. H. Palmer of New York for the construction of the canal; but failure of plans caused Central America to open negotiations with a Holland company, whose plans failed by the political disturbances in connection with the separation of Belgium from Holland in 1830.

As a result of rebellions, the Federation was partially ended by 1833. It was practically dissolved by 1839 by the legislative decree of 1838 granting each member of the Union the privilege of unrestrained action in the most important matters, and completely dissolved by 1847.

After the complete dissolution of the Federation, American diplomatic representatives to the separate republics were first sent to Guatemala in 1848, to Salvador in 1849, to Nicaragua in 1851, to Costa Rica in 1852 and to Honduras in 1853. Diplomatic representatives of the separate Central American states were received at Washington from Nicaragua in 1849, from Costa Rica in 1851, from Guatemala in 1851, from Salvador in 1853 and from Honduras in 1854. A commercial treaty was negotiated with Costa Rica in 1851. A similar treaty, negotiated with Nicaragua in 1849 and at subsequent periods, did not become operative.

Active American diplomacy affecting Central America really began with the military occupation of California and the resulting Colombia treaty of 1846 which was ratified in June 1848. The motive which attracted the American government to exercise a larger influence over the region was associated with the problem of the establishment and proper control of a new route to California. It was also connected with the development of canal plans by Louis Napoleon between 1844 and 1848, and consequent competitive English operations and plans in Central America, especially the occupation of the Nicaraguan port of San Juan (Greytown) which precipitated the intervention of American diplomacy and the negotiation of the famous Clayton-Bulwer Treaty (q.v.) of 1850 which guaranteed the integrity and independence of Central American territory and prepared the way for the extinguishment of any British claim of sovereignty or protectorate over the Mosquito Indians along the coast of Nicaragua—a claim which was finally terminated by the English treaty negotiated by Wyke with Nicaragua, in January 1860. On questions connected with these negotiations Central America requested and welcomed the support of the United States.

Boundary questions between Central American states furnished an opportunity for England to assert her earlier territorial claim. In 1852 Webster, acting under friendly mediation of the American government, submitted propositions for adjustment of such questions between Costa Rica and Nicaragua, but they were rejected by Nicaragua. In 1853, William Marcy, anxious to prevent European intermeddling in Central American affairs (and especially English encroachments in

Honduras), encouraged the reestablishment of the Central Federation, but he was not ready to pledge the American government to expel the British from the Bay Islands. After 1853, American diplomatic relations in Central America were affected by the constant apprehension of European influence inimical to American interests, and by a series of irritating events including the bombardment and burning of Greytown by Americans in 1854 as a punishment for an alleged insult to the American Minister to Nicaragua.

Relations were complicated by Walker's bold designs in connection with the political factions in Nicaragua, culminating in his conquest of Nicaragua and his election to the presidency of the country. By his expeditions, and by the filibuster diplomacy with which he vainly sought to gain recognition at Washington, he caused Nicaragua to present to the American government a series of claims for damages and created an ill feeling of all the Latin American representatives which culminated in the draft of the proposed treaty of alliance against the supposed designs of the United States.

The most important result of the Walker episode was the closure of the transit, causing a diversion of traffic which perhaps changed the destiny of Nicaragua.

In this period, by 1856, the American government adopted a more aggressive American policy in regard to control of transit and canal routes.

During the Civil War, the Central American people, seeing that the causes which produced filibustering, were passing away by the results of Union victories, and fearing the designs of all Europe (and especially of France) against American states, became more friendly to the government at Washington and anxiously hoped for the restoration of the Union. Soon after the fall of Vicksburg and the failure of Lee at Gettysburg, some advocated annexation to the United States. Others relying on the American government as natural protector of American republics requested alliance or aid. To them W. H. Seward replied that the most effective aid to American republics was the moral influence resulting from the integrity of the American Union and the stability of republican institutions.

The considerate policy of Secretary Seward during the Civil War period in forbearing to press claims of American citizens against the government of Nicaragua—claims which had long been a source of diplomatic irritation—unfortunately caused Nicaragua to regard the claims as abandoned and to refuse to negotiate a claims convention in 1871, although she agreed to a treaty of amity, commerce and navigation in 1867. The claims long remained a source of diplomatic discussion at intervals and were never settled.

Until the beginning of the 20th century the chief interest and attention of the United States in Central America, aside from the maintenance of the Monroe Doctrine, were centered in the possibility of constructing a transisthmian canal across Nicaragua. With the idea that the Nicaraguan route was more practical than the Panama route, an American canal company was organized in 1889—nominally to build a canal across Nicaragua, but really to induce the American government to take the responsibility in the enterprise. Until 1903, a violent controversy

ensued between the advocates of the two routes. With the idea of constructing a canal via the Nicaragua route the American government negotiated for the withdrawal of the Clayton-Bulwer Treaty which was finally terminated by the Hay-Pauncefote Treaty of December 1901. Soon thereafter, however, a decision was made in favor of the Panama route, disappointing the hopes of Nicaragua.

By 1917 the United States dominated the Central American market and invested in Central America more capital than any other country, and was thus more closely related to the country by economic bonds.

The American government, with a policy of forbearance and national unselfishness, too long allowed Central America to suffer from divisions, irresponsible leadership, revolution and bankruptcy. True, it sometimes used its good offices to prevent interstate conflicts, illustrated in 1888 by President Cleveland's arbitration of a long pending boundary dispute between Costa Rica and Nicaragua. With the hope of reducing sources of conflict it also urged a closer union and cooperation, recommending a return to the earlier policy of federation. In 1874 it began a series of friendly efforts to encourage the establishment of a strong and settled union, but practically abandoned its diplomatic efforts in that direction after the *pourparlers* of Blaine in 1881.

In 1896, the last attempt to restore the early federal union was made by the Presidents of Honduras, Nicaragua and Salvador, who (in accord with a treaty of 1895) formed, for the exercise of their external sovereignty, a single loose political organization with the title "Greater Republic of Central America" which was promptly recognized by the American government by the reception of a minister, but with the distinct understanding that the responsibility of each of the separate republics toward the United States remained wholly unaffected. Again the hope of the formation of a permanent federation was disappointed. In 1898, as a result of revolutionary movements—and especially a separatist movement in Salvador—the provisional executive council of the Greater Republic announced the dissolution of the union by mutual consent.

In 1906 President Theodore Roosevelt with the cooperation of President José Díaz, in order to terminate a war, acted as mediator in a dispute of Guatemala with Salvador and Honduras. This was in accord with the treaty of peace which received the assent of all the five republics except that of President Zelaya of Nicaragua, and directly recognized the obligation of the United States to mediate and intervene in Central American affairs. In February 1907 the American government failed in a friendly mediation to prevent Zelaya from making war against Honduras, but was able to prevent the spread of the conflict to Salvador and Guatemala. In August 1907, by strenuous diplomatic representations, it averted war between Nicaragua and Salvador.

At Washington, in 1907, through negotiations encouraged and stimulated by the United States on the initiative of President Roosevelt, the diplomatic representatives of the five separate republics held a Central American Peace Conference to find a basis of agreement on political, commercial and financial relations. The chief results were a series of palliative measures: the establishment of a Central American International Bureau as a

bureau of information (a miniature of the Pan American Union); the foundation of a Central American Court of Justice (five members) in Costa Rica, for the arbitration of questions of an international character affecting the relations of the five republics; and a provision for later Central American annual conferences to discuss political and economic questions of community interest.

The American government, after the derision which greeted the first decision of the new Central American Court, concluded that a court without means of enforcing its decisions was of no value—and reluctantly, but logically, concluded that American intervention was necessary to prevent depredations by the Zelaya government in Central America. In 1909, after the execution of two Americans in Nicaragua, it intervened directly, compelled Zelaya to flee and entered into a treaty agreement (negotiated by Secretary Knox) to act as a receiver for Nicaragua and to aid the new government in the rehabilitation of its finances. In the summer of 1912 it landed troops at the request of the Nicaraguan government to protect American lives and property and preserve free communication with the legation, and operated the national railway under the protection of American soldiers. It also negotiated a treaty, later approved by the Wilson administration, securing for its services in rehabilitating the finances sole rights to the construction of a canal across Nicaragua and to a coaling station in the Gulf of Fonseca. In August 1914 the Nicaraguan government was kept in power only by the presence of American troops landed at Bluefields.

The treaty, finally ratified by the American Senate in February 1916, providing substantial aid for the support of legally constituted good government in Nicaragua, was opposed by Costa Rica, who complained that it violated her rights. It was also opposed elsewhere in Central America on the ground that it would prove an obstacle to Central American union. The governments of Salvador and Honduras joined in the protest. Costa Rica brought suit against Nicaragua in the Central American Court of Justice at Cartago, Costa Rica. The court (in 1916) decided that Nicaragua acted illegally in selling canal rights without consulting Costa Rica, and in threatening the neutrality of Honduras by permitting a United States naval base to be established on the Gulf of Fonseca; but Nicaragua refused to be bound by the decision.

In 1922 new steps were taken to improve the situation in Central America where an arrangement for a federation had been repudiated by Guatemala in December 1921 and had disintegrated on Feb. 2, 1922, before the date selected for the birth of the proposed union. In August 1922, in the face of political troubles which threatened war, the United States obtained a meeting of the presidents of Nicaragua, Salvador, and Honduras on board the United States ship *Tacoma* in the Gulf of Fonseca to concert measures for establishment of more peaceful relations in Central America. These three executives agreed upon a renewal of the treaty of peace of 1907 with Costa Rica and Guatemala—a treaty which was later (in 1923) definitely recognized as still in force. As a result of this agreement and in acceptance of an invitation of the American government, the governments of the five Central American republics sent representatives

to Washington for a December conference on Central American affairs, with a view to negotiation of new treaties to insure permanent peace and cooperation among the Central American states. This conference agreed upon Pan American solidarity, but split on the issue of federation which was proposed by Honduras. It adjourned Feb. 7, 1923, after agreeing upon a treaty of peace and amity, 11 conventions, and three protocols. It accepted the jurisdiction of the new Central American Court over all controversies not settled by diplomacy arbitration, or some other tribunal. Later, Guatemala and Honduras agreed to submit their boundary dispute to President Harding for arbitration, and Costa Rica obtained from the United States government an agreement to consult Costa Rica directly concerning the latter's interest involved in the possible construction of the proposed Nicaragua canal by the United States.

Over a decade later the United States government, while negotiating reciprocal trade agreements (one of which was signed with Costa Rica on Nov. 28, 1936), showed a live interest in several Central American boundary disputes: one between Guatemala and Salvador which was settled on Jan. 24, 1934; one between Guatemala and Honduras which was settled in 1935; one between Costa Rica and Nicaragua which was finally settled in 1941; an old one between Nicaragua and Honduras which became heated in 1937 and was still pending in 1941; one between Costa Rica and Panama, adjustment of which was provided by a treaty of Sept. 26, 1938, but was delayed by strong protests resulting in withdrawal of the treaty from the Costa Rican Congress; and the Guatemalan claim on British Honduras which in 1941 was pending settlement, awaiting the outcome of the European situation.

Meantime, in 1938, 1940, and 1941, before American entrance into World War II, United States diplomacy was responsible for reduction of trade barriers between the Central American states and between the latter and the United States. It cooperated in plans for improved communication. In 1940 and 1941 United States loans to Nicaragua and Costa Rica aided in the further construction of the Pan American Highway across the Central American republics.

After entrance into the war against the Axis powers, the United States government increased its cooperation and influence in Central America. In November 1941, by an agreement of the preceding July, it cooperated with Costa Rica by furnishing a United States Army mission for training of the increased Costa Rican armed force which was needed in connection with an anti-Axis policy. In 1942, following the United Nations joint declaration of January 1, it also obtained from Costa Rica permission for United States military and air forces to use Costa Rican bases in the antisubmarine campaign and signed with it a lend-lease agreement. The wide extent of Central American collaboration and increasingly close relations with the United States in 1942, following the declaration of war against the Axis powers by the Central American states in December 1941, is illustrated by Guatemalan deportation of Germans to the United States for internment, the United States patrol of its Caribbean and Pacific coasts, and the union of Guatemalan forces with those of the United States "for hemisphere solidarity." All cooperated in the financial and economic policies and plans adopted

by the Inter-American conference for curbing Axis espionage and propaganda.

In 1942-1943 the United States government obtained agreements under which the United States Rubber Reserve Company contracted with Guatemala, Costa Rica, and Salvador to purchase all the surplus rubber of those republics for a period of five years. It also cooperated with the United States Fruit Company to shift its interest from banana contracts to a substitute program for developing the production of rubber, Manila hemp, quinine, and other articles needed in the war period. Meantime, it increased its interest in plans for improved communication across Central America. In July 1942 it announced the conclusion of arrangements with Guatemala and other republics for immediate linking of the finished segments of the Inter-American Highway between the Mexican-Guatemalan border and Panama City. In June 1943 it arranged to build across Costa Rica from Nicaragua to the Panama frontier another road for use in transportation of food supplies to the Canal Zone—planned as a strategic highway in case the Panama Canal should be blocked by war operations. JAMES M. CALLAHAN,
Professor of History and Political Science, West Virginia University.

CENTRAL CITY, city, Colorado, and seat of Gilpin County, at an altitude of 8,513 feet, a few miles from the Continental Divide, 26 miles west of Denver. It lies in a gold-mining district with mines that have produced a half billion in gold and silver since John H. Gregory's discovery of gold in 1859. The Teller House (1872), costing \$104,000 and named for Senator Henry Moore Teller, free-silver advocate, is still open for the summer season. The Central City Opera House (1878) is still standing. Since 1932 an Annual Play Festival is held there. The city was incorporated in 1886 and is governed by a mayor and council. Pop. (1950) 371.

CENTRAL CITY, town, Iowa, in Linn County, altitude 837 feet, on the Illinois Central Railroad. It is a trading center for farmer within a radius of ten miles. The town has a theater, a public library, a creamery, and a grain elevator. Pop. (1950) 965.

CENTRAL CITY, town, Kentucky, in Muhlenberg County, altitude 395 feet, 32 miles south of Owensboro, on the Illinois Central and Louisville and Nashville railroads. Coal, oil, and gas wells are nearby. The surrounding area raises tobacco, corn, hay, and garden produce. Pop. (1950) 4,110.

CENTRAL CITY, city, Nebraska, and Merrick County seat, altitude 1,705 feet, on the Platte River, and served by the Union Pacific and the Chicago, Burlington and Quincy railroads, and state and federal highways, 130 miles west of Omaha. It has a public library and is the seat of Nebraska Central College. It has a mayor and council. Pop. (1950) 2,394.

CENTRAL FALLS, city, Rhode Island, in Providence County; altitude 30 feet; on Blackstone River, adjoining Pawtucket; 4 miles north of Providence; and on the New York, New Haven and Hartford Railroad. An industrial city, it has textile mills and glass works (branch of the Corning, N. Y., works). Jenks Park and the memorial library were gifts to the city. In the park is a lofty memorial clock tower. The site of Central Falls was part of the town of Smithfield when the latter was cut off from Providence in 1730. It was incorporated with the town of Lincoln in 1871, and became a separate city in 1895. It is governed by a mayor and council. Pop. (1950) 23,550.

CENTRAL INDIA AGENCY, formerly the official British term for a collection of states and estates in Hindustan, with an area of 52,047 square miles and a population of (1941) 7,506,427. It was formed in 1854, and was an outgrowth of the interposition of the British government in Central India for the purpose of restoring order to a chaotic state of affairs that existed throughout that part of the country after the Pindari War in 1818. As a result of constant warfare and subjugation by invading forces, the territories of the different states became divided and intermingled. Their relations to one another and to the Indian government were various. Some were under direct treaty with the government of India; some were held under *sunnuds* and deeds of fealty and obedience; while others were held under agreements effected by the British government between them and their superior chiefs. The principal states were Indore, Bhopal, and Rewa, the largest of these being Rewa, with an area of 12,830 square miles and a population of (1941) 1,820,445. Indore was next in size, although first in importance because it was the residence agency; it had an area of 9,934 square miles and a population of (1941) 1,513,966. Bhopal was the smallest of the three, having an area of 6,921 square miles and a population of (1941) 785,322. In 1927, the king emperor recognized the right of a daughter of a ruler of Bhopal to succeed in the absence of a son; and a legislative council was established. In August 1947 all the territories became affiliated with the Indian Union.

CENTRAL OF GEORGIA RAILWAY COMPANY, a railroad company with headquarters at Savannah, Ga., and operating 1815.29 miles of track in Georgia and Alabama, including 4 miles to Chattanooga, Tenn. The company uses both diesel and steam power, but the trend is toward increased dieselization. Originally the road was incorporated Dec. 20, 1833, as Central Rail Road and Canal Company of Georgia, being the first railroad to be chartered in Georgia. In 1835 it was changed to Central Railroad and Banking Company of Georgia; and in 1895, it was given present name of Central of Georgia Railway Company. The first line completed was from Savannah to Ocmulgee River, near Macon, a distance of 191 miles. This line, completed in 1843, was for several years the longest railroad under one management in the world. The company is now in full corporate status, having emerged from trusteeship July 1, 1948. Two streamlined trains are operated—the *Man o' War* between Columbus and Atlanta, and *Nancy Hanks, II*, between Savannah, Macon and Atlanta. They

are the first streamliners to operate solely within the borders of Georgia. The company is joint operator with other railroads of the *City of Miami*, Chicago-Miami streamliner, handling this train from Birmingham, Ala., to Albany, Ga. Much attention is devoted to agricultural and industrial development in the area served, and complete staffs of agricultural and industrial experts are maintained.

CENTRAL PARK, New York City. Though now surpassed in size by several other park areas within Greater New York, Central Park is undoubtedly the most noted park in the metropolis, occupying, as its name implies, a central position in the Borough of Manhattan, the oldest borough of the city and the site of the city's first development. The park extends from 59th Street to 110th Street between Fifth and Eighth avenues and is 840 acres in extent.

In 1856, the year it was purchased by the city, the land now constituting Central Park was occupied by shanties, piggeries, and foul swamps nestled among rugged rock outcroppings. The site for the park was finally selected despite its uncompromising topography in preference to the location first proposed at 66 Street on the East River (Jones' Wood) because of its central position and greater area. An economic factor which was also considered at the time was the great expense of levelling off the site if it were to be adapted for building purposes, which would have entailed extensive filling of low swampy ground and blasting away of high rock ledges. It is interesting to note that the price paid for the park was about \$7,500 an acre, the total cost being \$6,348,959.90. The land has a present day valuation of \$645,250,000, an increase of over one hundredfold.

While many citizens, at the time of its purchase, readily predicted that the site would never lend itself for park purposes and that it was an unnecessary extravagance, plans were formulated and legislation enacted to go ahead with the improvement. As the result of country-wide competition, Frederick Law Olmsted and Calvert Vaux submitted plans which were chosen as the best of thirty designs and they were awarded the first prize of \$2,000.

Within a year construction work on the park was started under the jurisdiction of Olmsted, Vaux and Jacob Wrey Mould, an architect responsible for many of the early park structures. The original plan, now on display in the Park Department offices in the Arsenal in the park, was faithfully adhered to and the park today closely resembles that of seventy-five years ago, the most important change being the elimination of the lower reservoir of the old Croton system of New York City's water supply. This was filled in between 1930 and 1933 and, while many different schemes of development for the area were proposed, including a municipal music center, an elaborate war memorial, a huge swimming pool, and a golf course, it was not until 1934 that the present simple scheme for a Great Lawn was adopted, the area being completed in 1936.

Another change, and one which is quite apparent, has been the adaptation of the park to the requirements for active juvenile recreation. Robert Moses, who assumed the Commissioner-ship of the consolidated five-borough Park Department in 1934, found that, owing to the lack

of provision for active play, the park was deteriorating to an alarming extent through children's vandalism and directed the construction of 19 marginal playgrounds for small children around the perimeter of the park area. These playgrounds, located near pedestrian entrances, have been extremely successful in satisfying the need of children's recreation and it has become increasingly simpler to keep the balance of the park in good condition. In addition to these playgrounds the 29 acre North Meadow was laid out for active field games, two playgrounds were built in connection with the Great Lawn development, the centrally located playground in the southern part of the park which had been originally constructed with funds donated by August Heckscher, philanthropist, was enlarged and modernized, the Circle Lawn area for adults was reconstructed and another much-needed children's playground was built on the site of the Central Park Casino.

Other changes effected in the park under the jurisdiction of Commissioner Moses have been the replacement of the former unsanitary, unsafe menagerie with a modern, up-to-date zoo, and the conversion of the old conservatory and greenhouse group into a fine formal garden. The old Sheepfold, built in 1870-1872 as quarters for the park flock, used during the last century as the only means of keeping the lawns sheared, was converted, in 1934, into a modern restaurant with out-of-door dining terraces. This restaurant, known as the "Tavern-on-the-Green," serves moderate-priced meals to the public during the summer months. The present modest eating establishments in the Tavern-on-the-Green, the Zoo Cafeteria and the Boathouse on the Lake, replace, among others, McGowan's Pass Tavern, a famous old hostelry of the 90's where annually a magnum of champagne was donated to the first driver to reach the Tavern in his sleigh on the occasion of the first snowfall. The Central Park Casino, perched above the Mall, is another restaurant which has vanished from the scene. An eating place since the last century, it had become, in the late 1920's a pseudo-exclusive restaurant with exorbitant prices. After considerable litigation the Casino's management was ousted, the structure razed and the site developed as a playground for children.

While accurate figures are lacking, it is safe to say that over \$50,000,000 has been spent to date in bringing Central Park to its present condition. It is two and one-half miles long, a half mile wide and 147 of its 840 acres are in lakes and the large receiving reservoir of the New York City water-system. There are 35 miles of walks, 10¼ miles of road and five and one-half miles of bridle paths.

The Metropolitan Museum of Art occupies a site in the park fronting Fifth Avenue between 80th Street and 84th Street. Other items of interest are the Egyptian Obelisk, erected at the rear of the Museum, and the monument to the heroic dead of the U. S. S. *Maine*, situated at the southwest entrance to the park.

The Mall in Central Park is the center for special events. Band concerts are given in a band shell which was donated by Elkan Naumburg, philanthropist, and various other civic events and free entertainment, including free public dancing two nights a week during the summer months, are provided so that the Mall is used daily throughout half the year. Ten thou-

sand are easily accommodated in seats provided for the audience.

Activities in the park include boating in summer and skating in winter on the several lakes, lawn bowling, croquet, horseshoe pitching, model yachting, baseball, softball, hockey, football, riding.

An old count of visitors to the park made in 1861 showed an annual usage of 1,863,263 pedestrians, 73,547 equestrians and 456,849 carriages, the total number of visitors being estimated at 2,404,659. In comparison, in 1949, it was estimated that 4,697,000 people visited the park, of whom a large proportion were children in the various playgrounds.

CENTRAL PROVINCES AND BERAR,

a state in India, now called MADHYA PRADESH by the Constitution of the Republic of India, Jan. 26, 1950. The new state includes the Central Provinces and Berar and the 14 princely states of Chhattisgarh in the eastern districts. The state, an irregular square of land in central India between Bombay and Bengal has a total area, including the new acquisitions, of about 153,710 square miles. The population which was 16,813,584 in 1941 was increased to over 20,000,000 by the accession of the Chhattisgarh states. Madhya Pradesh is bounded in the northwest and north by the princely unions of Madhya Bharat and Vindhya Pradesh, in the northeast and east by Bihar and Orissa, in the southeast by Madras, in the south and southwest by Hyderabad, and in the west by Bombay. Physically the state may be divided roughly into three upland areas separated by two plains. The northwestern districts lie on the uplands of the Vindhya Plateau. South of this region are the wheat-growing plains of the Narbada Valley which are followed further south by the forested Satpura Range and the Nagpur Plain where the black soil is good for cotton growing. The eastern part of the Nagpur Plain lies in the valley of the Wainganga and is rice-growing country. Further east the Chhattisgarh region, also rice growing, is served by the upper reaches of the Mahanadi River. The southeastern extremities of the state are hilly and forested, until recently quite isolated, and inhabited by jungle tribes. The main rivers of the state are the Narbada, Wardha, Wainganga, and Mahanadi. The average rainfall for the whole state is about 47 inches, varying from 32 inches in the western parts dependent on the southwest monsoon to 62 inches in the east where the winter monsoon also operates. About one fifth of the state is not available for agriculture being hilly and wooded, but of the remaining land about 67 per cent is under cultivation. The percentage of rice to the total cropped area is 34, wheat 14, cotton 3, while pulses, cereals, oilseeds, etc., occupy 49 per cent. In 1945 there were 1,217 factories listed in the state which employed 110,263 persons. Nagpur, the capital, is a center for cotton spinning and weaving. Coal and manganese mined in the state in 1943 totaled 1,657,019 tons and 461,676 tons respectively. Marble and allied works such as limestone, pottery clay, and soapstone are operated around Jabalpur (Jabalpur). Four railways run in the state: the Great Indian Peninsular and Indian Midland; the Bombay, Baroda and Central Indian; the East Indian; and the Bengal-Nagpur. Two main routes connecting Bombay and Calcutta cross the state north and south of the Satpura Range.

Hindi is the lingua franca of the state, being spoken by 56 per cent of the people, while Marathi is spoken by 31 per cent. Oriya and Telugu are also spoken. Hindus numbered 13,336,372 and Moslems 682,854 in 1931, the last year in which the Indian Census included figures for religious affiliation. The administration was vested in a chief commissioner from 1861-1920, when the Central Provinces became a governor's province. The governor was assisted until 1935 by 8 secretaries and 6 undersecretaries, and after 1935 by a Council of Ministers summoned by him. The province after 1935 had a unicameral legislature of 112 members, and under the new Constitution of India, January 1950, it continues to be unicameral with 111 members. The new legislature is called the Legislative Assembly; representation in it is based on the scale of one member for every 75,000 of the population.

ROBERT O. SWAN.

CENTRAL RAILROAD COMPANY OF NEW JERSEY, The, a system operated in New Jersey and New York by The Central Railroad Company of New Jersey and controlled by the Reading Company which owns 57.52 per cent of the Class B stock. The company was formed Feb. 26, 1847 for the consolidation of the Elizabeth and Somerville Railroad Company and the Somerville and Eastern Railroad Company, and has since absorbed the Newark and New York Railroad Company, the Perth Amboy and Elizabeth Railroad Company, the Constable Hook Railroad Company, the Manufacturers Railroad Company, the South Branch Railroad Company, the High Bridge Railroad Company, the Longwood Valley Railroad Company, the Lake Hopatcong Railroad Company and Hibernia Mine Railroad Company. The lines owned amount to 360.24 miles, and the lines leased to 5.08 miles. The trackage rights held by the company total 45.20 miles.

Terminal facilities are extensive and include about five miles frontage in the Port of New York. While the Company's chief business is the moving of terminal freight, it also has a large commuting clientele, and furnishes through service in conjunction with the Reading and the Baltimore and Ohio railroads.

CENTRAL RAILROAD COMPANY OF PENNSYLVANIA, a system operated in Pennsylvania by the Central Railroad Company of Pennsylvania, a wholly owned subsidiary of The Central Railroad Company of New Jersey. The Company was formed Jan. 10, 1944 and is operating under lease since August 5, 1946, the lines of railroad in Pennsylvania formerly operated by The Central Railroad Company of New Jersey. The lines owned amount to 4.49 miles, and the lines leased to 184.82 miles. The trackage rights held by the company total 53.07 miles.

CENTRAL VALLEY, N. Y., town of Orange County; altitude 478 feet; 15 miles southwest of Newburgh; on the Erie Railroad. It is in a beautiful valley and there are large estates in the vicinity. The Palisades Interstate Park of New York and New Jersey, of which Bear Mountain is a part, and which comprises an area of 1,000 acres, lies to the east of Central Valley. Pop. (1950) 1,300.

CENTRALIA, Ill., city in Marion County,

altitude 490 feet, on the Illinois Central, the Chicago, Burlington and Quincy, and the Missouri-Illinois railroads, and, on state and federal highways, 60 miles by rail east of St. Louis and 252 miles southwest of Chicago. There is an airport just outside the city. The immediate environment of Centralia is industrial, but it is a business center for the southern part of Illinois, a rich farm belt. Fruit crops, particularly peaches, apples, Kieffer pears, and strawberries, have a high value. Extensive general farming and dairy farming is done in this region. The principal industrial activity is in drilling for oil and in refining it, but the city has factories in which shoes, stoves, ranges, heaters, and various cast iron articles are made. Originally a railroad town, Centralia is still a division point, with shops. The city has a public library. Centralia Junior College is located here. Founded in 1853, Centralia was made a city in 1859. In city-owned Fairview Park there are six oil wells; 12½ per cent of their production goes to the city. In 1938, in a referendum, the people of Centralia voted to use proceeds of these oil wells to build a new city hall. The town has commission government and the water system is municipally owned. Pop. (1930) 12,583; (1940) 16,343; (1950 est.) 18,500.

CENTRALIA, Mo., city of Boone County; altitude 884.53 feet; 22 miles northeast of Columbia, the county seat; on the Wabash, and Gulf, Mobile and Ohio railroads. It is in a fertile farming region, the farms raising corn, oats, hay, cattle and hogs. It ships coal and farm produce, and has manufactures of electrical line hardware and equipment, and hardwood lumber. Pop. (1940) 1,996; (1950) 2,500.

CENTRALIA, Wash., the Hub City of the Northwest, in Lewis County, is located midway between two great shopping centers, Seattle and Portland, on United States Highway 99, altitude 207 feet.

Since the settlement began in 1852 on the Oregon Trail, Centralia has developed into one of the largest cities in Southwest Washington.

Having a West Coast Marine type climate with a growing season of 173 days and an average rainfall of 45 inches, this is an ideal place to live. The temperature is moderate the year round, with no extreme heat in summer nor extreme cold in winter.

Being a shopping center, serving approximately 60,000 people, Centralia has many types of retail stores, ranging from small groceries to large department stores.

Four transcontinental railroads, a modern airport, leading bus lines, city buses, a radio equipped taxi service, dial system telephones and telegraph service, make up Centralia's transportation and communication conveniences.

The city has a modern publishing house for the newspaper that serves nearly 9,000 people daily.

Another important factor in the communication system is radio station KELA located between Centralia and the neighboring town of Chehalis.

A large Carnegie library and city park are located in the center of town. Lumbering is one of the major industries. Other important industries are coal mining, logging, manufacturing of

furniture and plywood products, glove and shoe factories, ice plants, modern bakeries, canneries, a candy kitchen and two large chick hatcheries.

Agriculture is a major industry, surpassed only by lumbering. There are about 4,200 farms covering 274,000 acres. There is a long pasture season, and an abundance of logged-off land for pasture use. The rainfall is adequate so that in most cases irrigation is not necessary. Grasses average from 3 to 5 tons per acre. The farmers may join the cooperative marketing group if they so desire. Some of the important agricultural activities are sheep raising, berry farming, dairy-farming, poultry raising, and vegetable and grain farming.

Near by is a modern armory and the National Guard has a large unit stationed here. There is a Navy training electronic school where various types of electronics are taught.

Centralia has one of the most fully developed school systems in Southwest Washington.

Centralia is one of the few cities in the United States that have a golf course within walking distance. There is an abundance of fine salmon and trout fishing in the streams near by. Hunting bear, deer and wild birds is enjoyed during their respective seasons and there is a modern state game hatchery adjacent to the city. The majority of the large fraternal organizations is represented. For year around entertainment there are theaters, bowling alleys, youth recreation center, and a skating rink.

The city government is commission form with a mayor and two city commissioners. The hydro-electric plant and municipal water system provide this city with ample, inexpensive power. And Centralia is proud to claim one of the most efficient and inexpensive systems in the United States. Pop. (1940) 7,414; (1950) 8,657.

CENTRANTHUS. See VALERIAN.

CENTRARCHIDAE, sĕn-tră'r'kĭ-dĕ, a family of fresh-water percoid fishes, confined to North America. The body is generally short, deep and compressed, with an equal curvature above and below, and covered with rather large, strong ctenoid scales. The mouth is terminal, variable in size, with the premaxillary protractile, and numerous fine, close teeth on all of its bounding bones. Both dorsal and anal fins are long, with 6 to 13 strong, sharp spines in the anterior part of the former, and 3 to 8 in the latter. All are active, pugnacious, carnivorous fishes, many of which build nests. They are important game and food fishes of small or moderate size, of which about 12 genera and 30 species are known, almost all of which are confined to the Mississippi Valley and the eastern United States, where they are almost the most characteristic fishes. The most important are the grass bass, black bass, rock bass, warmouth and sunfish.

CENTRE, Ala., county seat of Cherokee County; alt. 720 feet, on U.S. Highway 411, and 34.8 m. W. of Rome, Ga. Settled in the early 1840's and so named because of its central location in the county, Centre became the county seat in 1844. It was the home of John Jonathan Pratt, inventor of the pterotype, a precursor of the modern typewriter, described in the July 6, 1867 issue of *Scientific American*. Models of Pratt's machine are preserved in the Smithsonian

Institution, Washington, and the Kensington Museum, London. The inventor's grave is under a clump of oaks two miles west of the town. The *Coosa River News*, founded in 1878, is the local paper, and is still printed on a hand press. A mile from town is the Garrett House, built in 1830, and behind it the grave of Pathfinder, last chief of the local Cherokee tribe. Across the Coosa River is the site of Turkey Town, largest Indian town in Alabama in the early 19th century. The Cherokee of the district assembled there in 1837-1840 for their removal to Indian Territory. Pop. (1950) 1,672.

CENTRIFUGAL. A centrifugal (or centrifuge) as generally known, is a machine having a hollow rotor into which a mixture of liquids or a mixture of solids and liquids may be fed in such fashion that the mixture will be separated into its component parts by centrifugal force.

Though centrifugal governors, centrifugal pumps, centrifugal traps and centrifugal casting machines are all centrifugal machines, none is a centrifugal. Cream separators, centrifugal oil purifiers, sugar centrifugals and centrifugal laundry dryers are all "centrifugals."

From \$10,000,000 to \$20,000,000 worth of centrifugals are sold in the United States annually, and considerably over one half of this amount represents centrifugal cream separators.

For over 100 years centrifugals with large perforated rotors ("whizzers") have been used for the removal of liquids from such solids as sugar, and textiles. Since 1880 centrifugals have been used as cream separators. Some 2,000,000 cream separators are in use in the United States. The first cream separator was invented by the Cie de Fives Lille (France) in 1876. Cream separators were first manufactured in the United States (in 1887) by P. M. Sharples.

It is only since 1915, however, that centrifugals have been used for a wide variety of separations and purifications in chemical and other industrial plants. There are now over 400 different applications in the chemical, petroleum, and food industries for high-speed centrifugals of the general type of the cream separator.

Centrifugals are used (a) to separate two liquids, (b) to remove solid particles that are suspended in a liquid, and (c) to remove excess liquid that is in contact with solid matter. A description of several uses of centrifugals may be more interesting than descriptions of the machines themselves. Examples in each category are:

Category (a)—To separate two liquids:

Example 1: *Separation of cream from milk.* About 99 per cent of the cream that is in a given batch of whole milk may be removed by a centrifugal. The milk is fed through continuously and remains in the rotor but 5 to 15 seconds in order to accomplish this very complete separation. Only the extremely small fat globules remain in the skimmed milk, which latter will analyze about .04 to .08 per cent fat. By gravity separation in pans overnight only about five-sixths as much cream will be obtained, and the aging of the products incurred is a detriment.

Example 2: *Caustic Treating Vegetable Oils.* Cottonseed oil and other vegetable oils are commonly freed of free-fatty-acid by treatment with caustic. The mixture is then passed through a centrifugal for the removal of the reaction

products. These products can be, and until recently always were, removed by gravity settling, but the loss of oil with the removed impurities by that method is about 50 per cent greater than by the centrifugal method.

Example 3: Concentration of Rubber Latex. As the juice, or latex, comes from the rubber trees, it will contain some 25 per cent to 35 per cent of rubber in suspension. By passing this latex through a centrifugal, serum will be separated out and the resulting fluid concentrate will contain approximately 60 per cent rubber in suspension. This fluid concentrate can then be shipped with reasonable economy from the plantation to the country of ultimate manufacture, where rubber articles of superior quality can be produced, as compared with articles made from crude rubber in its solid form.

Example 4: Separation of Fish Oil from Water. In the manufacture of fish meal and fish oil, the fish are cooked in bulk, and pressed for the removal of liquids. The press effluent contains much water and some fish oil which latter is recovered by passing this effluent through a centrifugal. The recovery is practically complete and is so quickly accomplished that decomposition is prevented. This centrifugal separation has largely replaced the older method of gravity separation in tanks. In the latter case the solids present in the press effluent would decompose, thus lowering the quality of the oil. Furthermore, much oil would be lost.

Example 5: Dehydrating Insulating Oil. Transformers are usually filled with oil which acts as an electrical insulator between the wire coils and as a means of conducting away heat. It is common practice to pass this oil, at infrequent periods, through a centrifugal for the removal of moisture and other impurities, as these reduce the insulating power of the oil.

Example 6: Orange Oil from Orange Juice. When oranges and lemons are squeezed for the quantity production of juice, a small quantity of the valuable oil from the skins mixes with the juice. By passing the juice through centrifugals this oil is recovered.

Example 7: Wool-Grease Recovery. Wool, when shorn, is greasy with the body grease of the sheep. As the dirty wool is scoured in a bath of soap, alkali, and water, this grease and much other dirt is transferred to the scouring bath. By centrifuging these liquors, the grease is recovered. Some \$20,000 worth of this grease may be recovered annually from a pair of scouring trains. This wool grease, called lanolin when purified, is valuable as the base of salves owing to its power of penetrating the skin.

Category (b)—To remove solid particles that are suspended in a liquid:

Example 1: Purification of Lubricating Oil. When in use, lubricating oil becomes contaminated. When used in Diesel engines, it becomes contaminated with particles of carbon, sand, metal, water, acid, and sludge. By continually circulating this used oil through a centrifugal, the oil may be kept clean enough for use without damaging the engine's bearing surfaces.

Example 2: Separation of Wax from Lubricating Oil. An automobile lubricating oil, unless dewaxed, would become so viscous in cold weather that it would not pour, and the engine would be difficult to crank. This undewaxed oil would contain some 10 per cent to 20 per cent of wax. To dewax the oil centrifugally, it is

first diluted with a solvent, then chilled to perhaps -30°F. to solidify the wax, then passed through a centrifugal running at 15,000 r.p.m. The solvent is then removed from the oil by distillation.

Category (c)—To remove excess liquid that is in contact with solid matter:

Example 1: The large majority of the water is removed from wet cloth after laundering by placing the wet cloth in a perforated rotor of 20" to 50" diameter, and rotating it until the water is thrown off.

Example 2: In a similar way, the syrup is removed from sugar in sugar refining operations.

Example 3: Mother liquor is removed from ammonium sulphate crystals produced in a by-product coke plant. The centrifuged crystals will analyze about 2 per cent free moisture.

Centrifugals may be divided into the following mechanical classifications: (a) The Super-Centrifuge; (b) the disc-bowl centrifugal; (c) the self-cleaning disc-bowl centrifugal; (d) the continuous peripheral discharge centrifugal; (e) the batch centrifugal; (f) the continuous solid-discharge centrifugal; (g) the ultracentrifuge; (h) the bottle centrifugal. In industry the proper general type must, of course, be selected if optimum results are to be obtained in the centrifuging of any given mixture, and the proper model of the general type must be selected. A brief description of each classification and its use follows:

(a) The Super-Centrifugal. This generates the highest centrifugal force available for general industrial use. The 2" to 4" diameter rotors revolve at from 50,000 to 15,000 r.p.m. and generate centrifugal force equivalent to from 60,000 to 13,000 times the force of gravity. The fluid mixture is fed continuously into one end of the rotor, the separation takes place as the fluid flows through the rotor, and the separated fluids issue from separate ports at the exit end of the rotor. Any solid impurities that separate out remain deposited on the walls of the rotor and must be cleaned out at the end of the run.

(b) The disc bowl centrifugal. This machine runs at about one-half the r.p.m. of the Super-centrifugal but has a good efficiency due to a stack of cone-shaped discs which fill the bowl. These stratify the liquid in the bowl and thus render separation more rapid than it otherwise would be. In some instances the discs present a cleaning problem. Uses for this machine are largely identical with uses for the Supercentrifugal.

(c) The self-cleaning disc bowl centrifugal. Valves in the periphery of the rotor of this machine open themselves at intervals while it is in full speed operation and the solids are thus permitted to discharge through the peripheral openings. Such centrifugals are used where the liquids to be purified contain a relatively high percentage (say 1 per cent to 5 per cent) of insoluble solids.

(d) The continuous peripheral discharge centrifugal. This is a disc-bowl centrifugal so built that continuously it will disgorge itself of insoluble solids through nozzles near the bowl periphery. These solids, if allowed to accumulate, would fill and clog the bowl.

(e) The batch centrifugal. This is sometimes called a whizzer, a dryer, or a basket centrifugal. The rotor is usually from 30" to 80" diameter, and is usually perforated and lined

with wire screen. A slurry of granular salts and mother liquor may be placed in the rotor and as it revolves the liquid is thrown off through the perforations. While in the rotor, the salts may be rinsed with a spray of water. Periodically the dewatered salts are removed from the rotor. Bulk centrifugals are sometimes made so that they load, rinse the solids, dry them and unload them, all entirely automatically. These machines are sometimes made with imperforate baskets for purifying liquids. They usually generate a centrifugal force of only 500 to 1,500 times gravity, and therefore in spite of their size (in fact because of it) do not have the clarifying power of the smaller high-speed centrifugals previously described. Higher unit forces applied over such a large diameter rotor would burst it.

(f) The continuous solid-discharge centrifugal. This type machine usually has a mechanically driven plow which continuously plows the sediment out of the rotor as fast as it is deposited from the mixture flowing through it. This type machine is made with perforate as well as imperforate rotors, and in general is to be used for the same type work as the batch centrifugal.

(g) The ultracentrifuge. This is a small machine for laboratory work which revolves at extremely high speeds, generating a centrifugal force of from 100,000 to 7,000,000 times the force of gravity. The rotor usually operates in a very high vacuum (about .2 micron of Hg pressure). The use of vacuum prevents air friction on the rotor which would cause heating of the liquid sample in the rotor, which in turn would cause convection currents that would damage the extremely high separating efficiency of the centrifugal. The highest speed rotor ever made is $\frac{3}{16}$ inch diameter and runs at 6,600,000 r.p.m. generating a centrifugal force of over 13 million times the force of gravity.

(h) The bottle centrifugal. This centrifugal has a rotor made to hold several calibrated glass containers so that samples to be tested for laboratory analysis may be spun for a period, then removed so the percentage of settled material may be measured.

Evidences of centrifugal force continuously surround our everyday life. When a motor car proceeding down a street is forced to turn a corner by the action of the front wheels, the car as well as everything in it tends to continue straight on down the street. Centrifugal force has created this tendency. If an upright, half-filled bottle is fastened off-center on the top of a turn-table, and the turn-table is revolved at high speed, the water in it will be forced against the outer side of the bottle, and the surface of the water will go from a horizontal into a vertical position. If the water is muddy, the dirt particles will tend to go toward the outer side of the bottle, and soon the water will be clear and the mud will appear in a layer against the outer side of the bottle. If some oil had been mixed with the water, both the oil globules and the water would attempt to go to the outer side of the bottle, but the water being the heavier would have the preponderance of power and the oil globules would have to give way to the water. Hence, the oil globules, in spite of their desire to go outward, would go inward, because all the outward space would be pre-empted by the heavier water. Eventually one would find the mud on the outer side, next to it would be the water, and on the surface of the water would be

found the layer of oil particles. If the turn-table is now speeded up to four times its previous r.p.m., the mud particles will have 16 times (i.e. the square of 4) as great a tendency to reach the outer side of the bottle.

In this homely example are found the underlying principles of the high speed centrifugal. The liquid is revolved in a rotor at such high speed that mud will force itself outward to the wall of the rotor in a matter of a few seconds, and the oil globules will form a layer on the inner tubular surface of the water. A column of air will be found up the axis of the rotor. As more water is jetted into one end of the rotor, an equal amount of separated water and oil will emerge, or overflow, from the other end, and we have a continuous centrifugal in action. The oil and the water are permitted to overflow through separate outlets so they may be captured separately.

The earth may be considered as an enormous centrifugal rotor. The earth revolves at a speed of only $\frac{1}{1440}$ th of a r.p.m. Hence, in spite of its great diameter the centrifugal force generated is so slight as to be scarcely noticeable. A man weighed by a spring scale would weigh about one pound lighter at the equator than at the pole. The Mississippi River is caused to flow uphill by the centrifugal force generated by the rotation of the earth. The mouth of the Mississippi is about 3 miles higher than its so-called upper waters. The surface of the ocean is some 30 miles higher (further from the center of the earth) at the equator than at the north pole.

Following is the formula for centrifugal force:

A body revolving in a curved path of radius R in feet exerts a force called centrifugal force F upon the arm or chord which restrains it from moving in a straight line, or "flying off at a tangent." If W = weight of the body in pounds, N = the r.p.m., then

$$F = .00034084 WRN^2 \text{ lbs.}$$

Not all separation problems are most economically handled centrifugally. In industry there are five commonly used physical methods of separating liquid from liquid or removing solids from a liquid: (1) gravity settling; (2) filtration; (3) centrifugation; (4) distillation; (5) crystallization. Economic considerations usually determine which method will be used. If the solid particles will settle out readily from a liquid by gravity in a settling tank, method (1) may be the most desirable. (Example: settlement of mud from city water supply.) If the particles won't settle out readily but can be readily screened or filtered out, method (2) may be preferable. (Example: filtration of cement from a slurry.) If the particles won't settle readily and won't filter properly, method (3) may be the most desirable method. (Example: separation of cream from milk.) When the component parts of a liquid-liquid mixture are in solution one in the other, method (4) may be the most desirable. (Example: distillation of alcohol from water.) When a solid is dissolved in liquid, method (5) may be the most desirable. (Example: crystallization of sugar from a sugar-in-water solution.)

Vice President, The Sharples Corporation, Centrifugal and Process Engineers, Philadelphia, Pa.

CENTRIFUGAL FORCE, a phrase used to express the tendency manifested by a body revolving about a center to fly away. See also **CENTRIFUGAL**.

CENTRIFUGAL PUMPS. See **PUMPS AND PUMPING MACHINERY**.

CENTRIPETAL FORCE, that force operating on a body moving in a curve which tends to draw the body to the center of the curve. A moving body tends to move in a straight line. It may be deflected from its course into another straight line by some other impulse. If it is held continually to a curved path, it is under the influence of a centripetal force. A common illustration is the movement of the earth in its orbit. The inertia of the earth's motion tends to send it flying off into space in a straight line, tangent to the curve of its orbit. The attraction of the sun is the centripetal force which overcomes its inertia so far as to hold it steadily to the curve of its path around the sun. If the earth's forward motion were suddenly checked, the sun's centripetal attraction would draw it straight to the sun's center.

CENTROCLINAL FOLD. See **FOLDS**.

CENTROGRAPHY. The term implies the finding and recording of the geographical centers of population, area, wealth, or any other distribution on the earth. A map or cartogram recording such distribution is called a centrogram. To find the center of population of a country is in itself interesting enough, but if the trends of several years or decades can be established, important facts are revealed for land planning. The correlation of various centers, such as area and population, may bring out many hidden geographical relationships. Indeed, centrography became so important that a special organization, the Mendeleev Centrographical Laboratory, was established in Leningrad. Centrograms of cities and business areas are often prepared by telephone

companies, public utilities, and business firms. By establishing and projecting local trends, they have a scientific basis for buying real estate, and establishing branch offices.

There are various kinds of centers. The simplest is a *median point*. The usual way to arrive at a median point is the following. For instance, the median point of the population of the United States can be found by selecting a likely meridian and counting the population on one side of it. If it is less or more than half, then we have to move it until the population on both sides becomes equal. The same process is performed with a parallel, and the intersection of the parallel and the meridian is the median point.

Population will be equal in A and D quadrants (Fig. 1) and in B and C quadrants, but not necessarily the same in A and B. If we select two other lines than a parallel and a meridian, the result will be nearly but not exactly the same; the greater the number of units involved, the nearer will the results come. Many practices of centrography do not work well if very few individuals are involved. The method has another inaccuracy also. While the meridian is a great circle, and so the straightest line that can be drawn on a globe, the parallel is not. For exact work a great circle perpendicular (east and west) at the median point should be used instead of a parallel. It is obvious that the median point does not record the distance of the people from the center. The whole population of Illinois might move to Oregon without affecting the median point, the median point of the population of the United States being in west-central Ohio.

For most studies the median point will be sufficient, but if the distance is also to be considered we use the *center point of gravity*, or the *pivotal point*. The *Statistical Atlas of the United States 1874* (compiled by F. A. Walker) defines the center of population as a point upon which the United States would balance if it were a rigid plane without weight and the population were distributed thereon, each individual being

1. - The median point of population is located by bisecting the population with a meridian and with a parallel. (After Sviatlovsky and Eells, *Geographical Review*, 1937.)

Fig. 2.—The center point of gravity of the population of the United States progressed from Baltimore in 1790 to Illinois in 1950. (After U. S. Bureau of Census.)

assumed to have equal weight and to exert an influence on the central point proportionate to his distance from the point.

The finding of the pivotal point is similar to that of the median point. First we assume a central meridian and calculate the east-west momentum, and shift the meridian until east and west balance; then we do the same with a parallel; and the intersection will be the pivotal point. As we have to add individual distances instead of simple numbers, the calculation is far more involved than in the median point. The usual way is to find the center point of each state separately and work with the momentum of the state centers. The *pivotal point of the population* of the United States is near Carlisle in western Indiana. (Fig. 2.)

The steady westward migration of the center of population from Baltimore in 1790 to Olney, Ill., in 1950 is one of the most significant facts of

American history. This westward trend has slowed down since 1930; however, with the wartime industrialization of the West, the center is expected to be deep in Illinois in 1960. The *center of gravity of the area of continental United States* could be obtained by drawing on cardboard a map in azimuthal equidistant projection centered on the assumed center point, and cutting it out along the shore lines and balancing it on a pivot. Even this method would have a slight error and for still greater accuracy a spherical surface would have to be used. This center is near Lebanon, in north-central Kansas.

A third kind is the *center of minimum aggregate travel*. If all the people of a country would fly along straight lines to a national convention, the place which would require the least mileage would be such a center. According to most authors, this is identical with the center point of gravity, but according to W. C. Eells the points

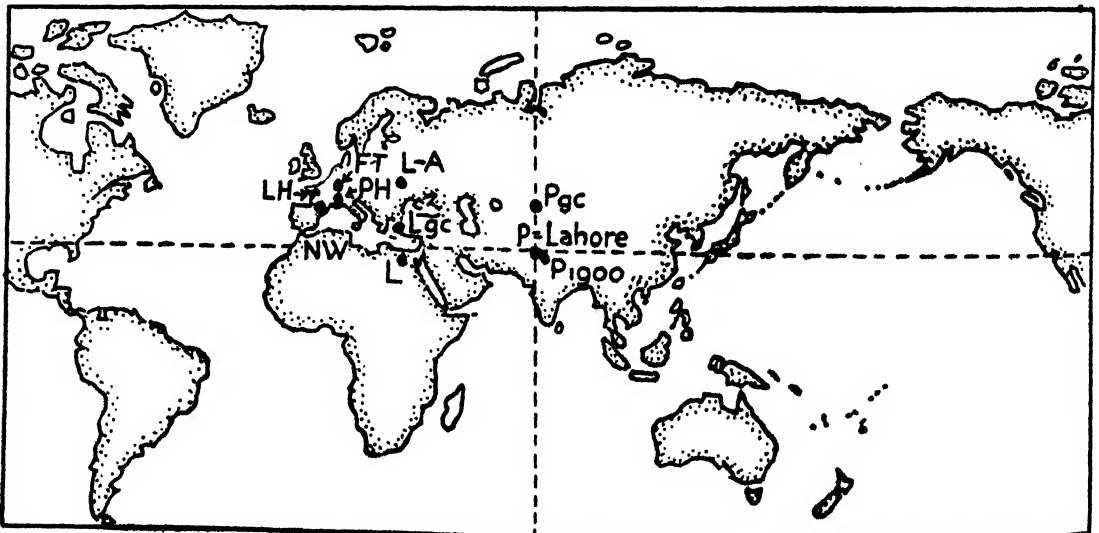

Fig. 3.—Median points. P = Population. P1900 = Population in 1900. Pgc = Population, using great circles. L = Land area. Lgc = Land area, using great circles. L-A = Land area minus Antarctica. NW = National wealth. LH = Land hemisphere. FT = Foreign trade. PH = People's hemisphere. (After Raisz, *Journal of Geography*, 1944.)

FIG. 4.—Centers of gravity of land areas. Cg = Center of gravity of all lands. Cg-A = Center of gravity of all lands minus Antarctica and Greenland. CgEH = Center of gravity of Eastern Hemisphere without Antarctica. (After Raisz, *Journal of Geography*, 1944.)

are not identical, especially if only a few individuals are considered.

Global Centrography.—Centrography, though laborious, is simple enough if the areas involved are so small that the spherical form of the earth is negligible, but to calculate the various centers of the whole earth allows for many interpretations.

Median Point of Land Areas.—Intersection of median meridian with median parallel locates one kind of center. There would be just as much land north of this point as south of it, and east and west would also balance. The problem can best be worked out on a cylindrical equal-area projection, and this point was located near Farafra oasis of Egypt.

A more significant median point can be found, if we bisect the earth's land area by a meridian

and a great circle perpendicular to it. This point is near Izmir in Turkey, and if we do not consider the ice cap of Antarctica as land the median point will be near Ternopol, Ukraine. (See Fig. 3.)

The center of gravity of land areas was obtained by taking a very light terrestrial globe and covering all the land areas with a sheet of lead of even thickness, then immersing it in water. The globe came to rest with a point on top representing the center of gravity of oceans and with a point at the bottom which is the center of land areas. This point is on the Black Sea border of Rumania, not far from Varna, Bulgaria. If we do not regard the ice caps of Greenland and Antarctica as land, the center will be near Baranovichi in White Russia (formerly Poland). The locations of these centers are significant. They all are found on a line where "East meets West" between Europe and Asia or the Soviet Union, and they are significant as future hubs of air communication. (See Fig. 4.)

Land and Water Hemisphere.—A land hemisphere is the half globe with the greatest amount of land. Although British atlases center it on London, and German atlases on Berlin, the actual center of the land hemisphere is near Nantes, France. Eighty-one per cent of all land is in this hemisphere and, if we do not regard Antarctica as land, the percentage rises to near 90, a really uneven distribution of land over the earth.

Centers of the Earth's Population.—The distribution of land on earth is uneven enough but still more unevenly are distributed the inhabitants of these lands. We can define a "people's hemisphere" as the half of the earth with most people in it. This hemisphere centers near Mont Cenis in the French Alps and contains 94½ per cent of the earth's population, a surprising concentration of the earth's people.

The median point of earth's population can be figured by bisecting the earth's population by a meridian and by a parallel. This kind of median point would show up well in a Mercator projection of any map with horizontal parallels.

FIG. 5.—Decilides of area and population. (After Sviatlovsky and Eells, *Geographical Review*, 1937.)

There are just as many people east of it as west of this point, and the same north and south of it. The opposite sectors, as northwest and southeast, will have the same population too. As for our common geographical conceptions, this seems to be the most satisfactory center and is located near Lahore, India, for 1940. The center has been calculated also for 1900 and is also near Lahore, India, although the earth's population was then 30 per cent less. This result is very remarkable as it shows uniform growth of the earth's population in all its four sectors. The median point, derived by bisecting with a meridian and a perpendicular great circle, is near Lake Balkhash in the Kazakh SSR.

No attempt was made to find the center of gravity of the earth's population because the result would not be significant. Any person near the antipodal point would shift the center point to an unproportionate extent, although it would matter but little to him from which direction to approach the center.

The Center of the Earth's Wealth.—Although the statistics here are less reliable, yet this line is conditioned so much by the parallels of New York and Chicago and by the meridians of London and Paris that this median point can be located with fair exactness in the eastern Pyrenees. Less significant but based on better data is the center of foreign trade which is on the Swiss-French-Italian border.

In these studies three groups of centers are apparent. While the centers of land area cluster around Istanbul (Constantinople), the centers of population in India, all the other centers—wealth, foreign trade, land hemisphere, people's hemisphere—cluster in and around France. It is likely that if the centers of culture, inventiveness, political and military power could be found, they also would center in western Europe. This central position with all its assets and liabilities will shape Europe's destiny for a long time. The increase of air transportation, the conquest of tropical diseases, and greater political and social security will result in a more even distribution of wealth and people over the earth, and the three groups of centers are likely to approach each other in the future.

Quartilides, Decilides, etc.—In establishing the median point of the population, we bisected the population of a country by a meridian and by a parallel. If instead of bisecting we divide the population into four, ten, or any other number of equal parts by meridians and parallels, we obtain quartilides, decilides, etc. These centers help to study local trends.

CENTROSOME, sən'trô-sôm, a term coined by Theodor Boveri in 1895, for the small bodies which Pierre J. van Beneden had earlier noted at the poles of the mitotic spindle of dividing

cells. Boveri saw within the centrosome of animal cells two smaller granules, which he called centrioles. The centrosome has been shown to be a transient structure, merely the innermost part of the aster of the mitotic figure. The centrioles, however, persist through the period between cell divisions, as a closely adjacent pair of minute bodies which are rarely over a hundred-thousandth of an inch in diameter. Centrioles stain intensely with such dyes as hematoxylin and crystal violet. They are also identifiable by their characteristic position in each type of cell; for example in a concavity of the nuclear surface (leucocytes, connective tissue, smooth muscle), just beneath the distal end of the cell (epithelia).

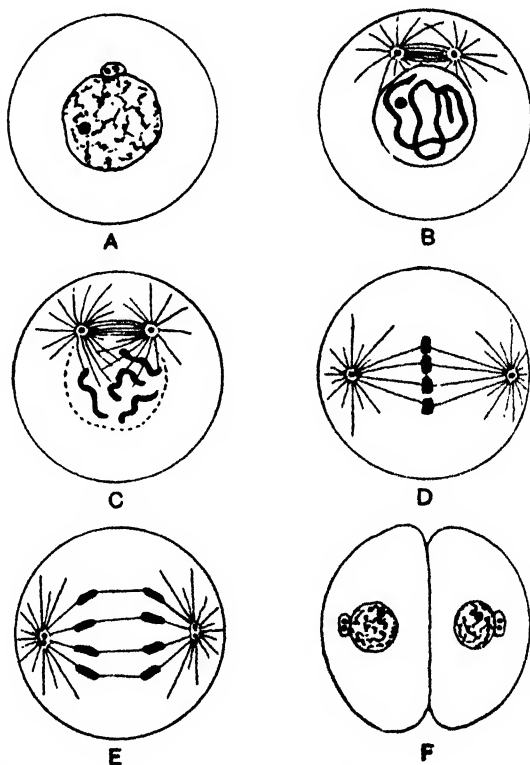

FIG. 1.—First division of an egg in which segmentation is complete. A, fertilized egg with nucleus and two centrosomes. B, the two centrosomes have moved apart, radiations have formed about them, and a "spindle" has developed between them. C, the wall of the nucleus is breaking down and fibers of the spindle are becoming attached to the chromosomes. D, the spindle is fully formed and the chromosomes have been drawn by it into an equatorial position. E, the chromosomes have divided and are being drawn to the two poles of the cell by the spindle. Each centrosome has divided. F, the first two cells of the embryo have been formed, each with two centrosomes ready to repeat the process at the next division.

In many types of animal cells there is no visible evidence of any function for the centrioles during the time between divisions; but in leucocytes an aster is developed about the centrioles, while in spermatozoa and unflagellated epithelial cells the vibratile process grows out from the centriole.

Centrioles are of great importance in cell division (Fig. 1). At prophase they separate and take up positions at either side of the nucleus, thus determining the location of the spindle and of the plane of cleavage which divides the parent cell into two daughter cells. While located at the spindle pole each centriole divides

to assure the double number to each daughter cell.

The facts summarized above are the basis of the view that in animal cells the centriole is a permanent cell organoid, which is self-perpetuating in much the same fashion as the chromosomes. The great puzzle about centrioles is concerned with the situation in plants. In many algae the facts appear much like those in animals (Figs. 2 and 3); but in gymnosperms and angiosperms the most diligent search has failed to establish the presence of a centriole in any cells, even at mitosis. In dividing cells of these plants, the spindle is barrel-shaped, and there is no hint of centrosome, centrioles, or asters. This could be interpreted as a permanent loss of the centriole-organoid in these plants; but this cannot explain the fact that in many mosses there are barrel-shaped spindles without centrioles throughout most of the life cycle, while spindles with centrioles appear in later generations of the plant, in those cells which are to give rise to the flagellated spermatozoa. It has always appeared therefore that in these mosses centrioles could not have arisen by division of pre-existing bodies of the same sort.

Recent researches have indicated that the centriole, although it is located in the cytoplasm,

FIG. 2.

FIG. 3.

is actually to be compared with a nuclear structure, the centromere of the chromosomes, a region to which the spindle fiber attaches at mitosis. In abnormal sperm formation in snails, it has been shown recently that the centromeres can become detached from degenerating chromosomes, enter the cytoplasm, and there behave exactly as if they were so many extra centrioles. It has been suggested that in the centromeres of the chromosomes there is, then, a permanent reservoir of centriolar substance, which could possibly be the source of the centrioles which appear so mysteriously in the sperm-forming cells of mosses.

ARTHUR W. POLLISTER,
Professor of Zoology, Columbia University.

CENTUMVIRS, sĕn'tŭm-vĭrs (Lat. *centumviri*, 100 men), Roman jurors competent to judge all cases in civil law except those concerning contracts, torts, and possession. Suits

involving questions of law rather than of fact were referred to them. No special qualification for membership is known, but the centumvirs seem to have been chosen from the upper classes. Sometimes they sat as a unit; more often they met in two or four sections, over which presided decemvirs (q.v.) as assistants to the hastarian praetor (q.v.), who nominally was their head. Decision was by majority ballot.

Originally 105 in number (3 elected annually from each of the 35 tribes among which Roman citizens were apportioned), when this panel was established about 150 B.C., the maximal strength reached 180 about 100 A.D. Our last certain reference to them is about 235 A.D.

CENTURIES OF MAGDEBURG, a history of the early Christian church, so called because it was divided into centuries, each of the 13 volumes covering a hundred years, and was first written at Magdeburg. Matthias Flacius Illyricus formed the plan of it in 1552, but the last volume did not appear until 1574. It is the first comprehensive work of the Protestants on church history; its main purpose was to prove agreement of Lutheran doctrine with that of primitive Christians, and the difference between the latter and that of the Roman Catholics.

CENTURION (Lat. *centurio*), in the Roman army one of the principal professional officers. He commanded a century (*centuria*), of which there were 60 in a legion. Theoretically a century comprised 100 soldiers, but the usual legion strength of about 6,000 men meant that the command of a centurion was normally about 60 soldiers. In general his rank and functions corresponded to those of a captain in modern armies. However, there were various degrees of rank among centurions; some of them fulfilled functions more like those of field than of line officers in modern armies. During the Republic they were promoted from the ranks; but under the Principate (Augustus and his successors) some were former equestrians (*ex equite Romano*) or former praetorians who chose a legion career because of the higher pay—it was five times that of a praetorian soldier—and better prospects on retirement. After the army reforms instituted by Gaius Marius (157–86 B.C.) during his consulships, each of a legion's ten cohorts had six centurions called, respectively, *pilus primus*, *pilus posterior*, *princeps prior*, *princeps posterior*, *hastatus prior*, and *hastatus posterior*. In nine of the cohorts there was little rank difference between centurions, but those promoted to the first cohort, having entered the *primi ordines*, were in a group where strict seniority prevailed, *pilus primus* ranking first. The Praetorian Guard also had centurions, as did the *Auxilia* which in the 2d century A.D. became assimilated to the legions.

CENTURIPAE, chân-tồ-rê-pâ, commune of Sicily, Italy, in the Province of Enna, 21 miles northwest of Catania, at an altitude of about 2,300 feet. It is an agricultural center and has sulphur mines in the vicinity. Located on the site of ancient Centuripae, which was colonized by the Greeks in the 4th century B.C., it became one of the most flourishing towns of Sicily; its prosperity continued well after the Roman conquest, as stated by Cicero. Excavations brought to light extensive necropolises, beautiful terra-cottas,

painted vases, and coins. It was destroyed in 1232 by Emperor Frederick II who resettled the inhabitants in Augusta (Agosta). Pop. (1951) commune 10,934.

CENTURY, in *chronology*, a period of 100 years. Modern chronology of Christian nations centers at the birth of Christ, and the centuries are numbered according to their order either before or after the event, for example, the 20th century A.D., the 4th century B.C. See also individual centuries such as **FIRST CENTURY** or **SECOND CENTURY**.

In *Roman times* (1) a division of 100 men in the army, corresponding to the modern company, 60 of which formed a legion; (2) a division of the six classes of the people, introduced by Servius Tullius, for the purposes of taxation and voting. See also **COMITIA**.

CENTURY PLANT, a popular name of the *Agave americana*. See **AGAVE**.

CEORL. See **CHURL**.

CEOS or **KEOS**. See **KĒA** or **KEOS**.

CEPHAELIS. See **IPECAC**.

CEPHALASPIS, sĕf-ă-lăs'pĭs, an extinct genus of armored fish, ostracoderm, of the Devonian period. This form and its relatives had characteristic external armor of bony rings or plates, a backbone of gristle, and presumably were the forerunners of modern fish. Fossil remains are found in large numbers in the red sandstones of Scotland, and in Quebec, Nova Scotia, and New Brunswick.

CEPHALIC INDEX, one of the standard measurements used in anthropometry, is the ratio of greatest width to greatest length of the head, expressed in percentage, the maximal length being counted as one hundred. If the skull is measured instead of the head, the term "cranial index" is sometimes used. If the breadth-length ratio is below 75 per cent the head (or skull) is said to be dolichocephalic or long-headed, if between 75 and 80 per cent it is meso- (or mesati-) cephalic, and if 80 per cent or above it is brachycephalic, short (or broad) headed. See also **ANTHROPOLOGY**.

CEPHALIZATION, the tendency exhibited in many different phyla of animals toward the specialization of the region about the mouth into a distinctive head, and the concentration there of nervous and sensory organs. In the chordates we find a clear development starting from the undifferentiated oral region of Amphioxus without any very special differentiation of its central nervous system and sense organs of the most generalized sort. The cyclostomes and fishes form the next stage, in which there is a definite, though small, brain, and the more important of the special senses (those of smell, sight, hearing, equilibrium) are centralized in the head, which acquires a special skeleton, the skull. We finally come to the terrestrial vertebrates, in which all the special senses become located in the head, the lateral-line sense and dermal chemical sense being lost. The increasing size and complexity of the brain is one of the outstanding features of vertebrate evolution. In

the arthropods we find a regular graduation from the equal segments of the chaetopod worms, which are probably not far removed from the primitive arthropod, to the well-defined head of the crayfish or insect, with its specialized eyes, antennae, jaws, and ganglia. The tendency toward cephalization is associated with the fact that the head is often the first part to take shape in the embryo; however, this fact, as exemplified by the trochosphere larva of the annelids, may indicate that the head of certain segmented forms is the true representative of the entire body of their ancestors, and that the formation of the segmented body may be the reminiscence of an ancestral multiplication by budding.

CEPHALOCELE, hernia of the brain. See **ENCEPHALOCELE**.

CEPHALOCHORDA, sĕf-ă-lō-kôr'dă, or **CEPHALOCHORDATA**, sĕf-ă-lō-kôr-dă'tă, a subphylum within the phylum Chordata found to include Amphioxus, the lancelet. Amphioxus was long considered a true vertebrate, but in view of its lacking a skull and a real brain, it was placed in a special division, the Acrania, all other vertebrates constituting the Craniata. Later, recognizing the unique extension of its notochord (q.v.) to the anterior tip of the body, Amphioxus was made the basis of a subphylum named Cephalochorda, the craniates forming a second subphylum Vertebrata. See also **AMPHIOXUS**; **CHORDATA**.

CEPHALONIA, sĕf-ă-lō'nĭ-ă (Gr. ΚΕΦΑΛΛΕΝΙΑ), an island of Greece, the largest of the Ionian Islands, northwest of the Peloponnese, at the entrance of the Gulf of Patras, about 31 miles in length and from 3 to 20 miles in breadth; area, about 289.4 square miles. With the island of Ithaca, Cephalonia forms the Department of Cephalonia, Greece. The coastline is very irregular and deeply marked with indentations, and the surface is rugged and mountainous, rising in Mt. Ainos to a height of 5,315 feet. One of the few rivers is the Rakli; the island is apt to be dry in summers. The principal towns are Argostolion, the capital, Lixourion, and Same. The leading agricultural products are currants (chief export), wine, olive oil, cotton, citrus fruit, and grain. Manufactures are very few.

History.—Cephalonia was an ally of Athens in the Peloponnesian War and later a member of the Aetolian League. It was taken by Rome in 189 B.C. and was held by Byzantium until captured by the Normans of Sicily in the 11th century. It was ruled by several Italian families until it passed to the Turks in 1479 and to Venice in 1499, which held it until the Treaty of Campo Formio (1797) gave it to France. Two years later it was seized by a Russo-Turkish fleet. By the Treaty of Tilsit (1807), Russia restored the island to France and by the Treaty of Paris (1815), a British protectorate was established over the Ionian Islands until they were ceded to Greece in 1864. It was occupied by Italy for a short time during World War II. Pop. (1940) island 57,384.

CEPHALOPODA, sĕf-ă-lōp'ō-dă, a class of mollusks represented by the squid, octopus, cuttlefish, nautilus, argonaut, and the ancient nautiloids and ammonoids. They are bilaterally symmetrical animals with a highly developed head

which is surrounded by a ring of elongated and mobile tentacles. These muscular tentacles are furnished with prehensile suckers which are usually provided with hooks. The head has two large and well-organized eyes, quite similar to vertebrate eyes, having a retina, iris, cornea, vitreous body and, other than nautilus, a lens. In most forms there is a cartilaginous brain case in which are grouped the cerebral, pedal, and visceral ganglia. In addition, there are well-developed hearing and olfactory organs. The mouth is provided with horny, beak-like jaws and a radula. The muscular mantle forms the outer walls of the body and this is unattached near the head so that water can be freely taken into the mantle cavity. The margin of the mantle is then appressed to the head area and the water forcibly ejected outward through a very flexible funnel. In this way, by changing the direction of the funnel opening, the animal can swim backwards or forwards, or quickly alter its course in either direction by the force and direction of the ejected water. Other than nautilus, existing forms have a sac filled with an ink-like fluid which can be expelled through the funnel. This clouds the water which acts as a screen behind which the animal may escape from its enemies. The "foot" of other mollusks has been modified in the cephalopods to form the tentacles and the funnel. The gills are well developed, either as one or two pairs which are situated within the mantle cavity. There are two kinds of hearts in each individual, the systemic and the branchial. The systemic heart consists of two or four (nautilus) auricles which receive the blood from the gills and a median ventricle from which arise the anterior and posterior aortas. At the base of each gill or paired gills there is the branchial heart which receives the blood from the *vena cava* and pumps it into the gills. Neither the branchial hearts nor the ink sac exists in any other class of mollusks. In most Cephalopoda reproduction is carried out by having the sperm lodged in elastic tubes, the spermatophores, which, by an elaborate arrangement, liberate the sperm after copulation. After the development of the spermatophores, these are passed into the funnel and on to one of the tentacles, then termed the hectocotylus, which has become modified for transferring the sperm. During copulation the hectocotylus is placed within the mantle cavity of the female and the sperm is then released by the spermatophores, fertilizing the eggs.

All cephalopods are exclusively marine animals, and, so far as the fossil record indicates, they have always been so. All are predatory, particularly on fish and crustaceans, and in turn are preyed upon by fish and many marine mammals, particularly the sperm whale. Certain species are among the largest invertebrates known. For example, the giant squid, *Architeuthis princeps*, reaches a length of fifty-two feet including the tentacles. Many of the pelagic and deep-sea forms possess luminescent organs. Many species have chromatophores on the surface of the body which are variously colored, and contractile pigment cells. These cells can be expanded or contracted so that only one pigment may be exhibited at a time. Thus there is a moderate but almost instantaneous change of color from dull red to a dull green.

So far as is now known, the embryology of the cephalopods differs from all other mollusks in that they possess a very large yolk sac and have

incomplete segmentation, and this is restricted to one end of the egg. There are no trochophore or veliger larval stages such as exist in all other Mollusca, development is gradual and direct, and the young are essentially similar to the adult. Octopuses and nautilus live mainly on the ocean floor at varying depths, from the intertidal realm out to over 100 fathoms. Squids, cuttlefish, argonauts, and spirula are pelagic, living in the open ocean and many of these exist at great depths. The genus *Eledonella* has been recorded from the depth of 2,900 fathoms or nearly $3\frac{1}{2}$ miles. The internal shells of spirula are frequently cast up on the beaches in considerable numbers, particularly in tropical areas. The shells being septate, and having chambers filled with gas, come to the surface when the animals die. Subject to both wind and current movements, they are carried hundreds of miles and may eventually reach shores far removed from their point of origin. The female paper sailor (paper nautilus) or *Argonauta*, when the breeding season is reached, produces a thin calcareous shell to act as a receptacle for protecting the eggs. It is believed that the shell is cast aside when the breeding season is over. In rather rare instances the shells are turned over and sufficient air is captured in the small spiral portion of the shell to enable it to remain afloat and eventually reach shore, though probably many more sink to the bottom than remain afloat.

The cephalopods are an old and apparently waning group of mollusks. Today some 170 genera and a few more than 400 species remain in our seas. About 600 genera and over 10,000 species of fossil cephalopods have been described, the earliest from the Upper Cambrian rocks. The nautiloids reached their greatest development during the early Paleozoic and the ammonoids reached their peak of development during the Mesozoic. The class Cephalopoda, both fossil and living forms, is divided into three subclasses:

Subclass 1. NAUTILOIDEA. Having straight and coiled chambered shells with slightly curved and transverse septa with the sutures simple. Possibly four gills were present in the fossil species such as now exist in the chambered, or pearly, *Nautilus*, the only living genus in this subclass. The range in time for the Nautiloidea is Upper Cambrian to Recent.

Subclass 2. AMMONOIDEA. Having coiled chambered shells with wrinkled septa, the sutures very complex and the shell with more or less sculptured exteriors. The number of gills present unknown, but possibly four in number. The range in time for the Ammonoidea is Upper Silurian to Upper Cretaceous.

Subclass 3. COLEOIDEA. Having an internal calcareous vestigial shell, or a chitonized rod or "pen," or none at all. There are 8 or 10 tentacles and two gills. To this class belong the squids, cuttlefish, the extinct belemnites, the *Argonauta* and octopuses. The range in time for the Coleoidea is from the Upper Mississippian to Recent.

In older classifications the Nautiloidea and Ammonoidea were grouped together as the subclass Tetrabranchia, and the subclass Coleoidea was called Dibranchia. This classification was based upon the number of gills present, four gills for the Tetrabranchia or two gills for the Dibranchia. However, modern authors, using additional characters rather than the gills alone, have divided the Cephalopoda into three subclasses as given above. The direct economic importance to man of the cephalopods is relatively minor. In many areas, particularly the Mediterranean, Japan, Polynesia, and the East Indies, they form an important item of food. Elsewhere, such as along the North Atlantic states and northern Europe, squids are used ex-

tensively as bait for commercial fishing. *Sepia*, long used as a dark brown pigment for water-color painting, is derived from the "ink" of *sepia*, the common cuttlefish of European waters. The internal shell or cuttlebone from *Sepia* and other allied genera has been a source of soft lime, used as an abrasive in dental work, and directly as a source of lime for caged birds.

WILLIAM CLENCH,
Curator of Mollusks, Museum of Comparative Zoology, Harvard College.

CEPHALUS, sĕf'ā-lūs, an Attic hero who was according to some the son of Deion, king of Phocis, and of Diomedes. He was the husband of Procris. Shortly after his marriage, Eos (Aurora) carried off the beautiful youth while he was hunting on Mount Hymettus. He refused the love of the goddess, who induced him to put the virtue of his wife to a trial which it could not withstand. Procris, in return, tempted him likewise, and he also yielded. Learning their mutual weakness, they became reconciled. But Procris subsequently became jealous of her husband, and concealed herself in a wood to watch him. He mistook her among the leaves for a wild animal, and killed her with a magical spear.

CEPHAS, sĕf'ās, or **KEPHA**, the name given to Simon Peter by Jesus (John 1:42). See also SAINT PETER.

CEPHEUS, sĕf'ūs, king of Ethiopia, husband of Cassiopeia and father of Andromeda. He is commemorated by a northern circumpolar constellation, bounded by Draco, Ursa Minor, Camelopardalis, Cassiopeia, Lacerta, and Cygnus. Its brightest star is Alpha (Alderamin), +2.60 magnitude, but its most famous is Delta which has given its name to the very important class of variables known as Cepheids. See also CASSIOPEIA.

CEPHISODOTUS, sĕf-i-sōd'ō-tūs, the name of two Greek sculptors, related to Praxiteles, who lived in the 4th century B.C. The elder was possibly an older brother of Praxiteles while the younger was his son. The most notable work of the elder was his group of Irene, goddess of peace, holding the infant Plutus, god of wealth. A copy is in Munich. The younger Cephisodotus was chiefly known for his statues of Menander, the writer of comedies, Lycurgus, the orator, and others, none of which remain.

CEPHISUS, sĕ-fi'sūs, or **CEPHISSUS**, the name of three rivers in Greece. (1) A river which rises in Mt. Pentelikon and waters the Athenian plain. It flows 20 miles southwest past Athens to the Bay of Phaleron of Saronic Gulf, east of Piraeus. (2) In Attica, a river of the same name rises in the Patera Mountain and flows 17 miles, east and south, to the Bay of Eleusis of Saronic Gulf. (3) This river, mainly in Boeotia, rises on the northern slopes of Mt. Parnassus and flows 71 miles east-southeast to the Gulf of Euboea, 10 miles west-northwest of Chalcis. In its lower course it forms lakes Hylike and Paralimne.

CERACCHI, chā-rāk'kē, **Giuseppe**, Italian sculptor; b. Rome, Italy, July 4, 1751; d. Paris, France, Jan. 30, 1802. After studying under

Tomaso Righi, he went to London in 1775 where he executed many commissions. In 1789, he went to America where he did portrait busts of George Washington, Benjamin Franklin, and Alexander Hamilton. Upon returning to Europe, while in Milan, he modeled a bust of Napoleon, who invited him to Paris. His republican sympathies induced him to join in a conspiracy against Napoleon. As a consequence, he was arrested and sent to the guillotine along with all but one of his fellow conspirators.

CERAM, sā'rām (also spelled SERAN or SERANG), second largest island in the Molucca Islands, Indonesia, lying between the Ceram Sea on the north and Banda Sea on the south, 100 miles west of New Guinea. The island is 210 miles long, 45 miles wide, and has a mountain range which rises to 10,205 feet in Mt. Binaija. There are several wide bays and the coastal plain is narrow. The principal products are copra, resin, fish, and sago, but rice, maize, sugarcane, spices, coconuts, and fruits are also raised. Hardwoods and other forest products are found in the dense forests here. Some oil has been found near Bula on the northeast coast. The chief port is Wahai on the north coast.

The natives live chiefly along the coast and are Malay mixed with some Papuan stock. A large number are Mohammedans but many Christians live in the west. Portuguese missionaries were here in the 16th century. In the early 17th century trading posts were established by the Dutch. The island came under Dutch control about 1650, where it remained until February 1942, when it was occupied by the Japanese as an airbase. At the end of World War II it was returned to the Dutch.

It is politically administered by the residency of Amboina, of the Moluccas. The Ceram census division includes the islands of Boano, Kelang, Manipa, and the Ceram Laut, Watubela, and Goram groups. The area of this division is 7,191 square miles. Pop. (1930) 100,029.

CERAMBYCIDAE, sĕr-ām-bis'i-dē, a family of beetles of the order Coleoptera commonly known as Longhorns or Longicorns, of which approximately 20,000 kinds have been described. The smallest species are only one fifteenth of an inch long, the largest over six inches. They vary enormously in shape but all are characterized by having long, usually tapering antennae which are often more than twice as long as the body: in the subfamily Prioninae they are usually serrate. The prionines are flattened, with parallel sides or somewhat tapering behind the thorax, and include the largest members of the family. Their strong mouthparts are capable of inflicting severe bites. The adult Cerambycidae are undoubtedly the most varied of all the beetles but the larvae are practically all borers in plants, a very small number living in the nests of ants. The adult habits are as varied as their appearances; some are nocturnal, some fly at dawn or dusk, while others love the brightest sunshine. Most of the diurnal species are brightly colored and many of those that visit flowers in order to feed upon pollen and nectar resemble bees and wasps while flying; others resemble and act like ants. When disturbed many of them are quite sluggish, but others drop instantly from a plant and take flight before reaching the ground: a few of them play possum. Species of *Urochaetes*

of the American tropics resemble bumblebees while the North American species of *Elytroleptus* mimic relatives of the fireflies.

The European musk beetle (*Aromia moschata*), about an inch long and metallic green, coppery and blue, gives off a scent that is said to be like attar of roses. The larvae live in dead willows. Adults in many genera are able to stridulate, and the chewing larvae in dead wood may produce a noise that can be heard several feet away.

Many of the species are pests of forest and cultivated trees and shrubs, although the vast majority attack dying or dead wood. While the larvae normally mature in from one to four years, depending upon the species, there are records of beetles emerging from furniture from 15 to 45 years after it had been manufactured. In such cases it is safe to assume that the curing and varnishing of the wood reduced both the palatability of the food and the amount of air present.

Among the most serious horticultural pests are species belonging to the genus *Oberea*. These are long and cylindrical and the female girdles the twigs of raspberries and related plants before laying an egg; the girdled tip eventually dies and the larva develops to maturity within it, even though it may fall to the ground. The apple-tree borer, *Saperda candida*, is a beautiful species with brown and white stripes on the elytra: originally a pest of hawthorn, it now attacks apples and is known as the round-headed apple-tree borer. Few forest trees escape attack by the Cerambycids. One of the most beautiful is the maple borer, *Glycobius speciosus*, golden yellow and black. Other variegated black and yellow species belong to the genus *Cyllocus*, the larvae of which bore in hickory, ash, elm, and black locust, while the adults visit flowers. Some groups are associated with conifers and may be serious pests in living trees.

CERAMICS. The productions of a potter. The word is derived from the Greek *keramos*, meaning a vessel made of baked clay. The French refer to the art of the potter as *céramique* and the vessels made as *poterie*. All types of earthenware, stoneware, and porcelain are included in the term ceramics. According to present usage, a distinction is made between opaque and translucent wares. All opaque wares, including not only earthenwares such as terra cotta, Italian majolica, French faience, Delft, and Queen's ware, but stoneware such as fine white English salt-glaze, are called pottery and all translucent wares are classed as porcelain.

The porcelains are divided into true or hard and artificial or soft pastes according to the nature of the ingredients and the temperature in the firing. For the true porcelain, a white refractory clay produced from the decay of feldspar and called kaolin or china clay is fused at a high temperature by means of a less decayed feldspathic material called petuntse or china stone. It is glazed with the china stone generally fluxed with lime and potash, producing a white translucent ware with an extremely hard surface which resists a file. The artificial or soft-paste porcelains are imitations of the true porcelain made of various mixtures of ground glass and other substances fused at a low temperature and glazed with lead glazes which are easily marked with a file. Bone ash was a characteristic ingredient of some Eng-

lish soft-paste porcelains in the 18th century. In the 19th century it became the standard ingredient with kaolin and petuntse in hard porcelain which henceforth was called bone porcelain. Parian ware and Carrara Statuary ware, named for the resemblance to white Italian marbles, are other 19th century varieties of porcelain.

The origins of both pottery and porcelain are lost in the past. Scholars believe the latter was evolved slowly in China over a long period, vessels of a porcelaneous nature having been found in Han grave mounds dating around 200 A.D. The introduction of the true Chinese porcelain into Europe in the 16th and 17th centuries stimulated the Western world to great activity in the field of ceramics and led to the improvement of techniques and bodies and the production of many imitative wares. In Italy successful attempts were made to imitate the Chinese porcelain at the end of the 16th century, but it was not until after 1709 when a young alchemist named Johann Friedrich Böttger (Böttcher) working in Saxony, discovered the ingredients of true porcelain, that its manufacture began in any quantity in Europe. The interest in Oriental wares also made itself felt in the refinement of earthenware and stoneware bodies and in their decoration. The tin-enameled wares of Delft, Strasbourg, Marieberg (near Stockholm), Niederwiller, Sceaux, Bristol, and Liverpool; the fine white English salt-glaze, and the cream color or Queen's ware, perfected by Josiah Wedgwood in 1763, all show this influence.

Ceramic techniques include the preparation of the clay; the shaping by hand, on the wheel, in the mold, or by casting; firing which renders it hard according to the intensity and duration of the fire; and the decoration with slip, glazes, pigments, tooling, turning, incising, piercing, printing, and relief work, molded, sprigged, or applied.

Glaze is a glassy coating, either opaque or translucent, colored or uncolored, which renders a surface impervious to liquids. Glazes are named from an ingredient as salt, tin, or lead; from the method of application as liquid, dry, or blown; from the color as green, mirror-black, or yellow; or from effect as shining, opalescent, or crackle when the surface is covered with a network of fine cracks. Painting is done under the glaze, in the glaze, or over the glaze.

As potters of East and West have always surrounded their activities and methods with secrecy, much ceramic history has been based on conjecture. Excavations on ancient sites in China, the Near East, in Egypt, and on the continents of Europe and America together with serious research on the part of many scholars have revolutionized ceramic knowledge in recent years requiring the revision of many books and museum collections. The attention of collectors has been directed to the Chinese tomb wares of the Han Dynasty 202 B.C. to 220 A.D. and the T'ang Dynasty 618-906 A.D.; to the fine stonewares and porcelains of the Sung Dynasty 960-1279 A.D.; to the Gabri ware, excavated chiefly in northern Persia, with graffiato designs of bird, flower, and animal forms; to the 14th century Italian Orvieto ware with linear painted decoration and the oak-leaf pattern majolica; to the Netherlandish majolica; and to many types of English earthen and stonewares. Among the latter should be mentioned the green glazed pieces, many cast in the form of cauliflowers and pineapples, long attribu-

ted to Thomas Whieldon, and the engine-turned red ware, long assigned to the Elers (John Philip and David), both of which are now known to have been made possible by Josiah Wedgwood's inventions of 1759 and 1763; the fine drab and white English salt-glazed ware, including the scratch blue type, no fragment of which was found in excavations on the site of the Elers factory, and which is now known to have been made by the Wedgwoods of Burslem and also during the partnership of Thomas Whieldon with Josiah Wedgwood (1754-1759) along with agate, tortoiseshell, glazed redware, and the shining black glazed pieces with applied vine reliefs formerly assigned only to Jackfield in Shropshire. Even the so-called Isleworth red and cane ware pieces have been traced to Bohemia in the mid-19th century. The study of English porcelains, chiefly by the English Ceramic Circle, has also resulted in discoveries and reattributions.

In America, the discovery by the late Rudolph P. Hommel of the Savannah potter Andrew Duché as a maker of porcelain in 1739 and his probable connection with the introduction of Cherokee clay in England is perhaps the greatest single discovery in regard to ceramics in America in recent years.

CERAMIC INDUSTRY

With the development of modern technology the ceramic industry has come to include the whole field of nonmetallic minerals which are given desired properties by treatment at high temperatures.

Clays and other silicate minerals remain the chief ceramic raw materials, although the oxides of magnesium, aluminum, zirconium, thorium, titanium, boron, and other metals are sometimes used, alone or in combination, with no silica present. All clays consist mainly of hydrous aluminum silicate ($\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$), differing in such factors as the impurities present and the size and shape of particles.

The most characteristic ceramic reaction is the formation of glass within the ceramic body as it is fired, by the fusion of some of the silica with the fluxes present. The fluid glass flows around the undissolved particles of higher-melting materials, forming a glassy matrix which, upon cooling, gives the fired piece its strength and rigidity. The glass formed will at first have the eutectic composition for the melting materials. For example, in a body containing silica (SiO_2) and alumina (Al_2O_3), liquid glass containing 5.5 per cent alumina and 94.5 per cent silica will begin to form at 2820°F. Because of such eutectic points in ceramic compositions, it is possible to fire ceramic ware at temperatures far below the melting points of any of the raw materials used.

Materials which help to form glass at fairly low temperatures are known as fluxes. The most important are sodium, potassium, calcium, and lithium compounds; magnesium oxide in certain proportions with silica is an effective flux.

Raw Materials Preparation.—Ceramic raw materials usually include small amounts of mineral impurities which may have important effects on firing temperatures, color, and other properties of the ware. When necessary, clays and other minerals are purified by washing, air or froth flotation, or magnetic or heavy-media separation, and are ground to carefully controlled degrees of fineness before being added to a batch for the production of ceramic ware.

Methods of Forming.—Ceramic materials which are sufficiently plastic are formed by extrusion, pressing or "jiggering." A jigger is a machine-age adaptation of the potter's wheel, on which thin bats of clay are placed after being extruded in an even column and cut to the desired thickness. The turning wheel is a plaster mold, the shape of the concave side of the piece to be made; a die which shapes the outer side is brought down against the bat as it turns. Hundreds of dozens of pieces of flatware are produced daily in dinnerware plants using automatic jiggers. Unsymmetrical pieces which cannot be jiggered, such as hollowware, sanitaryware, and electrical porcelains are often cast, using a "slip" of clay mixed with water. In 1948 there was devised a method of automatically pressing plastic clay bodies many times faster than casting, and superior to jiggering in some applications. Water from the clay is absorbed by the porous plaster dies used in pressing, and is drawn off by vacuum. The usual drying period is eliminated. Relatively nonplastic bodies whose moisture content is only 5-15 per cent, such as electrical insulators, tile, and pure refractory oxides, are often formed by dry pressing in hydraulic presses under high pressure. Large refractory pieces are often rammed into the mold with a mallet or air hammer.

Brick and tile are molded or cut from an extruded column, as are many types of porcelains. High-speed, automatic presses have long been used for making intricate shapes of electrical porcelain. The highly mechanized methods of making glassware are described in the articles on GLASS-MAKING and GLASS MANUFACTURING IN AMERICA. Porcelain enamel is being applied more and more by spraying, although dipping (slushing) and the dry-process method are still used.

Firing.—The traditional round or beehive periodic kiln for firing ceramic ware is rapidly being replaced by tunnel kilns in the larger ceramic plants. The tunnel kiln has the advantages of continuous operation and closer temperature control, as the ware is pushed through the kiln on cars rolling on a track. Heat and time are not lost in cooling the kiln between firings. Gas is the cheapest and most used fuel, although oil and coal are both important. For smaller kilns and for closely controlled firing, and in enameling ovens, electric heating is often used. Glass is melted in tanks with hundreds of tons capacity, and here too the continuous process has replaced the older methods. Mixed "batch" is fed into the tank at one end, and the melted glass is drawn continuously from the other.

Glass.—Technologically, silicate glasses are the common denominator of most of the ceramic industry, as has been indicated above, and glass is in some ways the most typical ceramic product.

Most commercial glasses contain a large proportion of silica, although there are other metallic oxides which will form useful glasses when fused and allowed to cool. A whole series of glasses, for example, is based on phosphorus pentoxide (P_2O_5) and contains no silica; boric oxide (B_2O_3) is also a good glassformer.

As may be expected from the above comments on eutectics, sodium and calcium oxides melted with silica produce a comparatively low-melting glass. A triple eutectic occurs at the composition 21.3 per cent Na_2O , 5.2 per cent CaO , and 73.5 per cent SiO_2 , with a melting point of about

1340°F. The most ancient man-made glasses are found to have this approximate composition, and about 90 per cent of the glass made today is this soda-lime-silica glass. It has been modified, however, to gain better physical and chemical properties. Using more lime and less soda gives better chemical stability, but increases the tendency of the glass to devitrify (crystallize). This in turn is counteracted by adding small amounts of magnesia, alumina, or boric oxide. Since other oxides may be added as decolorizers, oxidizing agents, and for other effects, the commercial soda-lime glasses of today are quite complex.

Glass with a large proportion of lead oxide was developed in England during the 17th century, and is still widely prized for its clarity. Crystal tableware is lead glass. Since World War I borosilicate glass, containing 12 to 15 per cent of B_2O_3 , has come into wide use because of its great heat-shock resistance, high mechanical strength, and chemical stability. Called Pyrex, it is seen in cookingware, laboratory equipment, glass-lined pipe, and hundreds of other forms.

Whiteware.—Most of the common products known traditionally as ceramics are included in the whiteware group. Pottery and porcelain are described at length in the articles under those headings. It is sufficient to say that pottery, semivitreous ware, and vitreous porcelain or chinaware are basically similar, composed of clay (kaolin and plastic ball clay), flint (ground silica sand), and feldspar ($K_2O \cdot Al_2O_3 \cdot 6SiO_2$ or $Na_2O \cdot Al_2O_3 \cdot 6SiO_2$). They vary through an infinite variety of proportions, with many other minerals used with the above, and particularly they vary in the temperature to which they are fired. The translucency prized in vitreous ware is the result of the formation of a high proportion of glass in firing, which fills all the pores of the fired body. This is not true of the semivitreous bodies, and earthenware is quite porous and will not hold water unless glazed.

Sanitaryware, which includes sinks, lavatories, and similar items, also comes under this category. Dental porcelains, consisting principally of kaolin, quartz, feldspar, and various metallic oxides for coloring, are used for artificial teeth and crowns, and for inlays.

Electrical porcelains are those used for insulators of all kinds. For low-tension circuits, clay-flint-feldspar porcelains similar to those mentioned above are used. For high-frequency use, as in electronic equipment, special compositions made largely of steatite talc (a magnesium silicate) are used, and in certain cases bodies containing titanium and zirconium compounds have advantages. Spark plug insulators, which combine great heat-shock resistance and chemical inertness with very good insulating qualities, are probably the most efficient ceramic insulators yet developed. Shortly before World War II a method of making these insulators from nearly pure alumina (Al_2O_3) was perfected, and they are made in quantities of millions daily. In a unique process the alumina body is mixed with an organic plasticizer and insulator shapes are injection-molded. The plasticizer burns out when they are fired at temperatures of about 3200°F. Synthetic mica ceramics with dielectric properties equal to or better than most other ceramic dielectric insulators have been developed for such applications as general machinable ceramics, electrical insulation, frictional resistant materials, and for radar domes.

Special whiteware products include precision gauges for metal, guides for the textile industry, nozzles for pressure blasting equipment, pressing and extrusion dies, chemical porcelain, heat-resistant thermocouple and pyrometer protection tubes, burner tips and elements for industrial heating equipment, dipping forms for the manufacture of rubber gloves, and similar items. Abrasion and heat resistance plus chemical stability make ceramic products superior to metal in a wide variety of uses.

Porcelain Enamel.—Enamels are complex glasses, designed for a special purpose. They must expand with heat at the same rate as the metal to which they are to be applied, or they will crack and craze on cooling. The basic glass is smelted and quenched by pouring in water; it is ground and then sold as "frit." To the frit are added opacifiers, colorants, and about 15 per cent of plastic clay, which aids in forming the desired thin film on application.

Tin and antimony oxides were for many years the chief opacifiers, and enamels had to be applied in two or three thick coats, burned at 1500° to 1550°F. Since World War II titanium and zirconium oxide opacifiers have made possible much thinner coats with better covering qualities. One thin coat is often used, fired to only 1300°F. on ordinary cold-rolled sheet steel; for the higher temperatures expensive "enameling iron" is needed, as the ordinary types soften and warp. Wide use of enamels in architecture has made this development necessary. The development of an enamel coating for aluminum has increased the use of this material where a lightweight, hard, permanent finish surface is desired for structural and decorative uses. See also ENAMELS AND ENAMELING.

Refractories.—All modern industry is dependent upon refractories to control and contain heat. The steel industry, for example, uses about one dollar's worth of refractories for each ton of steel made.

Fire-clay brick are the most widely used refractories, being used wherever extreme temperatures or chemical action is not present. Various types can be used at temperatures up to from 2900° to 3400°F. Alumina is often added to the clay body for added refractoriness.

Brick of nearly pure silica are used where high compressive strength is needed at high temperatures. Sillimanite and kyanite (both forms of $Al_2O_3 \cdot SiO_2$), sometimes mixed with clay, are used as refractory brick and for other refractory shapes.

Cast blocks and shapes of fused alumina, first produced in the 1930's, soon became standard for glass tanks; cast zircon-alumina blocks are considered superior for some parts of tanks. Magnesia, beryllia, thoria, and lime are used for special refractory purposes. Silicon carbide (Carborundum) refractories are used for kiln furniture, kiln muffles, and other uses where high thermal conductivity and great refractoriness are needed.

Chromite brick contain about 40 per cent chromic oxide, 20 per cent alumina, 25 per cent iron oxide, and some magnesite and silica; magnesite brick are about 88 per cent magnesite. Both types are used to line open-hearth furnaces and in other metal-refining uses.

Carbon and graphite are also used extensively as refractories. The volume stability of carbon makes it less subject to shrinkage than clay re-

fractories for blast furnace hearths. It is also used in certain types of furnaces for melting copper, lead, and aluminum, and in electric furnaces. Graphite, which has high thermal and electrical conductivity, is often preferred to carbon in refractories because it forms a stronger body. Mixed with clay, graphite is widely used for metal-melting crucibles since it provides a reducing atmosphere which prevents oxidation of the metal being melted. It also has nuclear properties which make it valuable in a reactor.

Structural Clay Products.—The making of brick, tile, and related products is one of the oldest of industries and has remained, technologically, one of the most backward. The raw materials used are the more common clays and shales, with sand or lime added. Glazed brick and tile are a higher quality product, and the white floor and wall tile are more nearly a whiteware product. The chief advances in this field in modern times have been in brickmaking machinery and firing methods, not in compositions. (See BRICK; CLAY-WORKING AND BRICK-WORKING MACHINERY.)

Competition from other materials and rising costs have forced the clay products industry into large scale activity in research only since World War II. Lightweight clay products were a primary objective; these are made quite porous and are conveniently used in larger units. Another trend is that toward standardization in the development of modular units of brick and building block. Development of prestressed structural ceramic products has resulted in lighter structures capable of carrying larger loadings. High fuel costs for firing are being cut by finding cheap fluxes to reduce firing temperatures; feldspar and the other common fluxes of the whiteware industry are too expensive for the structural clay field.

Abrasives.—Synthetic abrasives are made of several ceramic products. Boron carbide (B₄C) is the hardest man-made mineral and silicon carbide and fused alumina are extremely hard. These and other abrasive materials are formed into wheels and other shapes by being fired with

small amounts of other ceramic materials or organic resins, which act as a bond.

New Uses of Ceramics.—Ceramic materials can stand up under conditions which no other substances can withstand. Special refractories for use as turbine blades and combustion chamber linings for jet engines were found necessary with the development of this type of engine; other ceramics help to control the heat of atomic fission. Refractory enamels applied a few thousandths of an inch thick make metals able to withstand temperatures hundreds of degrees above their melting points for a short time. A new class of materials called cermets or ceramals consists of metallic and ceramic substances combined in one body, with some of the properties of each.

Professional Organizations.—The American Ceramic Society was founded in 1898 and the British Ceramic Society was founded in 1900. Both have published technical literature continuously since those dates. Other leading technical organizations are the British Society of Glass Technology and the German Ceramic Society. American Ceramic Society publications were circulated in 43 countries in 1950.

The Canadian Ceramic Society was founded in 1902. Publications include: *Journal of the Canadian Ceramic Society* and *The Clay Products News and Ceramic Record*.

Société Française de Céramique was founded in 1947 and is comparable to a specialized research institute. It publishes its own *Bulletin* and contributes to the magazine, *L'Industrie Céramique*.

Bibliography.—The publications of the above-named organizations are the chief sources of technical ceramic information. For more popular reading the following are recommended: Andrews, A. I., *Enamels* (Champaign, Ill., 1935); Phillips, C. J., *Glass, the Miracle Maker* (New York 1941); Newcomb, Rexford, Jr., *Ceramic Whitewares* (New York 1947); Rosenthal, Ernest, *Pottery and Ceramics* (London 1949); Savage, George, *Ceramics for the Collector—An Introduction to Pottery and Porcelain* (New York 1949); Litchfield, Frederick, *Pottery and Porcelain*, 5th ed., rev. by Frank Tilley (New York 1951); Rackham, Bernard, *Early Staffordshire Pottery* (London 1951); Bemrose, Geoffrey, *19th Century English Pottery and Porcelain* (London 1952); Christensen, Erwin O., *Early American Designs* (New York 1952); Norton, F. H., *Elements of Ceramics* (Cambridge, Mass., 1952).

CERARGYRITE. See SILVER—Silver Ores.

CERASTES, sê-rās'têz, the venomous horned vipers of North Africa. There are two species, *Aspis viper* and *Aspis cornuta*, both of which were formerly referred to the genus *Cerastes*, a name now shifted to a group of rear-fanged snakes in Africa. Horned vipers use "side-winding locomotion," a means of progression particularly adaptable for crawling over loose sand. The same method is employed by snakes in other desert regions, notably the American sidewinder or horned rattlesnake (*Crotalus cerastes*). Horned vipers are largely active at night; during the day they bury themselves in the sand, with only the head exposed.

CERATOPSIA. See DINOSAURS—Order *Ornithischia* (Suborder Ceratopsia).

CERATOSAURUS, sêr-â-tô-sô'rûs, a carnivorous dinosaur resembling *Allosaurus* but only reaching a length of about 20 feet. It was of

bipinnate form, and derives its name from the small horn found on the nasal bone. See also DINOSAURS.

CERAUNIAN MOUNTAINS, sê-rô-ni-ân, a coastal range of southern Albania in the northern Epirus, extending about 70 miles from the Greek border to the Strait of Otranto, where it divides into the Acroceraunian and Lungara ranges. Its highest peak, Mt. Çikë, in the northwest, rises to about 6,727 feet. The name Acroceraunia is sometimes applied to the entire system. See also ACROCERAUNUM.

CERCIS, sûr'sis, a genus of deciduous trees or shrubs of the family Leguminosae and characterized by attractive clusters of pea-like blossoms. *C. canadensis*, the redbud, is a handsome tree with heart-shaped leaves, and is native to most of the eastern United States. In parts of the Central states, wherever it has been able to survive at the edge of a woodland, its great masses of deep rose blossoms, mingled with the white of neighboring dogwood, provide a springtime display that is famous for its beauty. This redbud is often cultivated, and horticultural varieties exist with double or white flowers. Redbud is sometimes called Judas tree, a name better reserved for *C. siliquastrum*, native to southern Europe and Asia, and traditionally associated with the Biblical story of Judas as the tree from which he hanged himself. The western redbud, *C. occidentalis*, is native to California and east to

CERCOPITHECIDAE, sûr-kô-pî-thê'sî-dê, a family within the primate suborder Anthropoidea, which in most taxonomic systems includes all the old world (Asiatic and African) tailed monkeys, but not the anthropoid apes. See also MONKEYS; PRIMATES.

CEREALS. The word cereal is derived from the Cerealia, Roman ceremonies held in honor of Ceres (q.v.), goddess of grain. Cereals are grasses grown for their edible seeds. Botanically, they belong to the family Gramineae. Their seeds are used both for human consumption and livestock feed. They include wheat, oats, barley, rye, rice, proso millet, maize, and grain sorghum. The last two are called row crops as they are usually planted in rows far enough apart to permit intertillage; the others are called small grains.

In some countries pearl millet, teff, and Job's tears are also considered cereals. Only maize originated in America; millet and sorghum are probably indigenous to tropical Africa or Arabia, and the other cereals came from Eurasia.

Growing Conditions.—Physiologically, the small grains are classified as long-day plants with the exception of rice. Rice, maize, sorghum, and millet are short-day plants. All cereals are annuals, but there are winter-annual types of wheat, oats, barley, and rye that are sown in the fall in areas where winters are moderate and summer temperatures and humidity are high. At present, wheat, oats, barley, and rye are grown under relatively cool conditions, wheat being most widely distributed. Oats and barley are grown in the more temperate climates, and winter rye is the hardest of the small grains. Rice, maize, and sorghum are warm-season crops, rice being unique in that it can germinate and thrive in

water. Proso millet is a short-season crop grown on a small acreage in the areas of spring-sown grains in the United States.

The small grains are usually sown in rows six or seven inches apart, although in some areas they are sown broadcast. Maize and sorghum are usually planted in rows that are cultivated primarily for weed control. Large areas of the cereals are sown and harvested with modern machinery designed for maximum efficiency. In the United States and Europe, rapid progress has been made in the control of weeds by spraying with growth-regulating herbicides. Disease and insect problems are being solved in many instances through the development of resistant varieties to which a tremendous amount of effort is devoted throughout the world. Primitive cultural methods are still used, however, in parts of the Orient, India, Africa, and Central America.

The net result of growing cereal crops is a reduction in soil productivity. Depletion of organic matter and nitrogen is especially true of row crops because of the cultivation. Sorghum and millet frequently have a depressing effect on the yield of crops that follow. Where cereals are grown in rotation, grass and legume crops are included and sometimes used as green manures to restore in part the nitrogen, organic matter, and tilth of the soil.

Uses.—Wheat and rice are the dominant cereals used as food. Wheat is the major cereal in the world grain markets. Only wheat and rye can be classified as bread grains. Bread flour is usually made from hard wheats while the best cake and pastry flours are made from soft wheats. Macaroni, spaghetti, noodles, and similar products are made from durum wheat. Only about 14 per cent of the wheat crop in the United States is fed to livestock and poultry on the farm, but byproducts of milling, such as bran, shorts, and middlings, are sold for feed. Black bread from rye flour is common among certain Europeans, but rye bread eaten in the United States is a mixture of rye and wheat flours. Whiskey and alcohol are made from rye, and small amounts of rye are fed to livestock in mixtures with other grains. Wheat is the chief cereal in the national diet of the United States, but rice is the principal food crop for crowded populations of the Orient. Damaged rice and byproducts of milling are fed to livestock.

The major part of the world's barley and oats crops is fed to livestock on the farm. Large quantities of barley are used to produce malt, and the grain is used for human food in parts of Africa, Asia, and Europe. A small percentage of the oats crop is used for food, principally in the form of cooked oatmeal. The bulk of the American corn or maize crop is fed to livestock and poultry, hogs consuming the largest amount. About 10 per cent of the United States crop is used for food and industrial products, such as cornstarch, corn oil, and alcohol. It is the principal food in parts of Mexico and Central America. Millet and sorghum are used almost entirely for feed in the United States, but millet is the chief cereal in parts of Africa, India, the Soviet Union, and China where it is eaten as porridge or ground into flour and made into cakes. The distribution of cereals as flour per person in per cent of total calorie supply in 1951 was: China 73, Asia as a whole 67, Africa 63, Europe 42, South America 39, Oceania 28.5, and United States 25.

World Production.—In 1951, the cereals accounted for 65 per cent of the total production of major crops of the world, excluding the Soviet Union for which there are no reliable statistics, and occupied 73.5 per cent of the total acreage. Wheat was grown on the largest acreage of any crop, the other cereals in the following descending order: rice, maize, millets and sorghum, barley, oats, and rye. Largest in production was rice, a relatively high-yielding crop, followed by wheat, maize, oats, millet and sorghum, barley, and rye.

Since the five-year period of 1934-1938, the most significant changes in cropping and crop production in the world, exclusive of Russia, have been: (1) a marked increase in the acre yield of wheat in North and Central America and a decrease in both acreage and production in South America; (2) a large increase in the production of maize on fewer acres in North and Central America due largely to the use of hybrids, and an increase in acreage and production in Africa; (3) an increase in production of oats in North America largely because of better yields per acre, and a decrease in acreage and production in South America; (4) an increase in acreage and production of barley in North America; (5) a reduction in acreage and production of rye in North America; (6) an increase in acreage and production of sorghum in North and Central America and a decrease in both acreage and production of millet in Europe; and (7) an increase in acreage and production of rice in North and Central America, South America, and Africa.

Those areas of the world that produce more cereals than they consume and export their surplus are the Soviet Union, North and South America, and Oceania. Deficit areas that import cereals are Europe, Asia, and Africa.

The leading areas of production for each cereal crop are indicated in the following table by the percentage of the total world acreage sown in 1951:

	Africa	Asia	Europe	North and Central America
Barley		41	24	19 *
Maize	10	20	13	47
Millet and sorghum	19	61		
Oats			36	55
Rice		93		
Rye			86	
Wheat		38	22	28

* Figure for North America only.

In the United States, maize was grown on the largest acreage followed by wheat, oats, barley, millet and sorghum, rice, and rye. The same order was true for production. In 1951, the United States produced 57 per cent of the world production of maize on 40 per cent of the acreage; 19 per cent of the wheat on 19 per cent of the acreage; 38 per cent of the oats on 41 per cent of the acreage; 11 per cent of the barley on 10 per cent of the acreage; 8 per cent of millet and sorghum on less than 5 per cent of the acreage; 1 per cent of the rice on less than 1 per cent of the acreage; and less than 3 per cent of the rye on 5 per cent of the acreage.

R. S. D.

BREAKFAST CEREALS

The manufacture of modern breakfast cereals began in the late 19th century. Although oatmeal porridge and mush have been eaten since Colo-

nial days, oat cereal became popular only after about 1860 when Ferdinand Schumacher of Akron, Ohio, learned to roll the grains flat instead of grinding them into fine flour. This made it possible to cook them into a less pasty and more appetizing product. Cracked and rolled wheat cereals soon followed.

With the turn of the century "cold" or ready-to-eat cereals were invented, virtually revolutionizing the American breakfast by providing a wide variety of tasty, nourishing cereal products in ready-prepared form.

Wheat flakes and corn flakes were first developed as a health food by Dr. John Harvey Kellogg at the Battle Creek Sanitarium, Battle Creek, Mich., originally established by a group of Seventh-Day Adventists, where a vegetarian diet was part of the treatment. In 1906, a younger brother, Will K. Kellogg, finally incorporated the Battle Creek Toasted Corn Flake Company and, in a few years, many different brands of corn flakes appeared on the market. Charles W. Post, a former patient at the sanitarium, established himself at Battle Creek and began inventing cereal products. His first ready-to-eat cereal was made by baking whole wheat and barley into loaves which were dried and ground into small pieces. The product (Grape Nuts), marketed in 1898, was so successful that it was distributed nationally within a few years. The discovery of Henry Perky of Cambridge, Mass., in the 1890's that boiled whole wheat prescribed for his health could be made more palatable by pressing it into long filaments, led to the product now known as Shredded Wheat. Puffed wheat and puffed rice were developed as the result of experiments on starch grains by the chemist, Dr. Alexander P. Anderson. Heated to about 500°F. in a closed test tube in which the pressure was suddenly released by breaking, the granules exploded and swelled to ten times their original size. By 1904, Dr. Anderson had developed the puffing process for rice and wheat; they were first sold as breakfast cereals in 1904 and 1907 by the Quaker Oats Company.

From these early beginnings, methods have been perfected so that grains can be flaked, rolled, shredded, puffed, baked or ground to yield products which vary in flavor, form, and texture. Through the application of food research, modern processing, packaging, merchandising, and advertising, the manufacture of breakfast cereals has developed into a huge industry in the United States and has spread to other countries. From the outset, the cereal industry has devoted a great deal of attention to packaging to assure maximum protection and freshness of the product. Today, all breakfast cereals which are nationally distributed are packaged. The ready-to-eat varieties are generally sold in moisture-proof packages to preserve crispness. The consumption of breakfast cereals is about 7 pounds per capita, of which the ready-to-eat cereals make up about 65 per cent. Oats, wheat, and corn are the leading grains used by the industry in the order named. The introduction in 1949 of sugar-coated or "presweetened" cereals, as the industry prefers to call them, has become an important factor in the market.

Hot cereals consist of two types: granular products, such as ground whole wheat, farina, and corn meal; and flaked products, such as rolled oats and rolled wheat. Granular whole wheat is made by grinding cleaned, washed wheat be-

ween corrugated rolls and sifting through bolting sieves to yield a product of rather uniform particle size. Granular whole wheat contains all the bran, germ, and endosperm; in making farina, however, the bran and germ are removed.

In the manufacture of rolled oats, selected oats are cleaned, graded according to length, and then dried to facilitate removal of the hulls and to develop flavor. Hulling is accomplished on impact machines which release the oat kernels or groats. After removal of the hulls, the groats are treated with water and steam so that they can be pressed into flakes by the heated flaking rolls with a minimum of shattering. Two types of flakes are produced: those rolled from whole groats (so-called "old-fashioned" rolled oats); and those from groats which have been cut on rotary cutters (so-called "quick" rolled oats).

Ready-to-eat cereal breakfast foods are made in a wide variety but they may be classified into two general types: those made from entire grains or their mill products; and those made from fabricated cereal products. Both of these types are manufactured in the form of flaked, shredded, granular, puffed, and toasted foods. The manufacture of each breakfast cereal requires its own series of milling, flavoring, cooking, flaking, rolling, puffing and drying, or toasting operations.

Flaked cereal products include corn flakes, wheat flakes, bran flakes, and rice flakes. In the manufacture of corn flakes, hominy grits (large fragments of corn endosperm) are mixed with flavoring materials, thoroughly cooked, dried to the desired moisture content, and rolled into flakes between heavy rollers. The flakes are then toasted.

Puffed breakfast cereals include puffed wheat, puffed rice, and puffed products which are fabricated from doughs, such as Kix and Cheerios. The grains or doughs to be puffed are enclosed in a pressure chamber, or puffing gun, and heated. When the desired water vapor pressure has been reached, the gun is allowed to open and the sudden expansion of the water vapor and air results in the explosion or enlargement of the cereal particles.

Adding Vitamins.—The addition of essential B vitamins and minerals to improve the nutritive value of cereal products has been an important development of the 20th century. In refined cereal products from which the bran and germ have been removed the biological value of the protein and the quantities of B-vitamins and minerals are lower than those of the original cereal. The heat processing involved in manufacture destroys part of the thiamine and impairs the nutritive value of the proteins.

Products made from processed cereals are either "restored" or "fortified" by addition of B-vitamins and minerals. For restoration, sufficient amounts of thiamine, niacin and iron are added to attain the natural or whole-grain levels. In fortified products, certain minerals or vitamins are added to give quantities in excess of those found in the original cereals; vitamin D, not normally present in cereals, may be added. Differences in the nutritive value of the proteins of different breakfast cereals, depending upon whether they are made from whole-grain or refined cereals and upon the extent of heat, are obliterated when consumed with equal weights of milk. Breakfast cereals owe much of their prestige to the application of nutritional research findings in their manufacture.

Cereal Coffee Substitutes.—Roasted cereals have long been used as substitutes for coffee. Postum Cereal, which was developed by Charles W. Post in the late 1890's, is a representative product of this type. It is prepared from whole wheat carefully roasted, granulated, and then blended with a similarly roasted mixture of bran and sugarcane molasses. Instant Postum, a soluble vacuum-dried extract of Postum Cereal, was placed on the market in 1912.

Cereal Foods for Babies.—Precooked cereal foods in dry form for use in infant feeding are manufactured on a large scale. These preparations require only the addition of milk for feeding and are so compounded as to provide an excellent source of high quality protein and of essential B-vitamins and minerals. In addition to one or more cereal products, they contain such ingredients as powdered beef bone, dried yeast, salt, sodium iron pyrophosphate, thiamine nitrate, riboflavin, and niacin in such proportions as to provide food which will contain desirable quantities of the essential B-vitamins and minerals. In some of these infant foods, the refined cereal component is obtained from a single grain such as wheat, barley, oats, rice, or corn; a preparation is also made in which a mixture of cereal flours is employed. The cereals are carefully refined to remove the bran and germ, yielding a product of low fiber and fat content which will have little tendency to become rancid.

The ingredients are mixed with hot water and fed to drum dryers which consist of two large heated cylinders that revolve in opposite directions. The mixture is cooked in the space between the drums and, as they turn, they pick up and dry a film of the cereal on their surfaces. The dried material is shaved from the rolls in a continuous sheet by knives and passed through flaking machines. It is usually then toasted to produce the desired moisture, color and flavor, allowed to cool, and packaged. CEREBRAL HEMORRHAGE. See
APOPLEXY.

CEREBRAL PALSY (also known as **SPASTIC PARALYSIS**, **CEREBROSPASTIC PARALYSIS**, **LITTLE'S DISEASE**, and **INFANTILE CEREBRAL PALSY**) is a condition characterized by paralysis, weakness, incoordination, involuntary motion, or any other aberration of motor function caused by brain injury. The injury to the brain occurs most commonly at the time of birth, and may be the result

of head trauma during the birth process, or of interference with the oxygen supply to the brain. It occurs more commonly, therefore, when labor is difficult or abnormal, or when the child is weak or debilitated, as in prematurity. Less frequently, damage to the fetal brain can occur even before birth as an effect of disease of the mother or involvement of the placenta. Incompatibility of blood types of the mother and baby (the Rh factor) is a cause of cerebral palsy. Occa-

cause cerebral palsy. The incidence of the condition is about one in 250 live births.

Cerebral palsy occurring in infancy or early childhood, before full growth and development have been attained, generally causes more profound and irreversible handicaps than when it occurs in adults, as from strokes, or in older children after full intellect, speech, hand skills, and locomotion have been achieved.

The degree of disability is dependent upon the site and amount of damage in the brain. Sometimes, damage is so slight that the individual may have only a mild clumsiness or incoordination of the hands, or a slight loss of balance in walking, or a minor speech impediment. In very severe cases, the individual may be confined to wheelchair or bed and be totally dependent upon others. At times, speech may be so involved that verbal communication is impossible. In some patients, only the right or left half of the body is affected. In others, both legs may be involved, so that walking is associated with a waddle and the typical "scissors gait," with one leg crossing over the other. Complete loss of hand function might make it impossible for one to give himself any degree of self care. In some individuals drooling and grimacing motions of the face, flailing motions of the arms, and unsteadiness in gait, may result in a rather unprepossessing appearance.

Because the brain controls so many functions other than purely motor acts, it is common to have other defects associated with cerebral palsy. Thus, defective vision or hearing, convulsive tendencies, intellectual impairment, and personality changes may occur in cerebral palsy. These associated defects may in some instances be more disabling than the motor disability by itself.

For many years, it was thought that all children with cerebral palsy were hopeless crippled idiots who would never walk or help themselves. Advances in the field of rehabilitation and in evaluation of the true mental status of the cerebral palsied indicate that over 50 per cent of them can be rehabilitated and many of these can profit from an educational program.

M. A. PERLSTEIN.

CEREBRON, sĕr'ĕ-brŏn, or **PHRENOSIN**, one of the three major cerebroside, found in the brain tissues and to a lesser degree in the nervous system. It has the empirical formula $C_{17}H_{35}NO_8$, and contains the fatty acid cerebronic acid, $C_{18}H_{35}O_8$. It is manufactured by mixing macerated ox brain with acetone, allowing to stand for 48 hours, filtering, and repeating the process. The residue, cleaned of impurities, is dried and extracted extensively with petroleum ether. The cake residue is then ground to a fine powder and the phosphatides are removed by extraction with alcohol in which cerebrin is soluble. Upon hydrolysis, using dilute acids, cerebrin is converted

into a monosaccharide, the fatty acid galactose, and a nitrogenous substance known as sphingosin, $C_{17}H_{35}NO_8$, which can reduce Fehling's solution.

CEREBROSIDES, sĕr'ĕ-brŏ-sids, a class of substances resembling in appearance the solid fats, such as tallow, which are found in nerve and brain tissue, egg yolk, and the spleen. They belong to the general class of natural products known as lipids (see BIOCHEMISTRY). An idea

of these substances are broken up by the action of chemicals with the addition of hydrogen and hydroxyl groups, the simpler substances which result include: the sugar, galactose, which has the same composition and slightly different structure from glucose, $C_6H_{12}O_6$; alcohols containing an amino group, NH_2 ; fatty acids; and choline, which has the formula $(CH_3)_3N(OH)CH_2CH_2OH$. Some of these materials also contain phosphoric acid, H_3PO_4 , in combination.

CEREMONIAL, Court. See COURT CEREMONIAL.

CEREMONIALE, a liturgical book of the Catholic Church containing directions or formularies, or both, for the celebration of public services and the administration of sacraments. Such books date from about the 16th century, being successors of the old *Ordines* and the *Rituales libri*, or *Libri agendarum*. Various churches and religious orders had, or have, their own ceremonials.

Caeremoniale Romanum, or *Rituum Ecclesiasticorum sive Sacrarum Caeremoniarum Sanctae Ecclesiae Romanae libri tres non ante impressi*, was compiled about 1488 by Augustinus Patricius, or Patrizi, but was first published in 1516 at Venice under the name of Christophorus Marcellus. It comprises ceremonies which are papal in character, and copies of it are scarce; there is a fine two-volume edition with extensive commentaries by Joseph Catalani, published at Rome in 1750.

Caeremoniale Episcoporum, published by Pope Clement VIII in 1600 and revised in 1650, 1721, and 1741, has the force of liturgical law throughout the church. It contains directions, or rubrics, for Mass, Vespers, and other services. Conceived with cathedral or collegiate churches in view, it applies, with the necessary modification, to all Catholic churches.

ALASTAIR GUINAN.

CERES, sĕr'ĕz, in Roman mythology, the name of an Italic goddess identified with Demeter (q.v.), when the latter's cult was introduced into Italy. The origin of her name, which is not Latin, is uncertain. Some think it Oscan; others consider it Etruscan, for Ceres (so Servius says) was one of the Etruscan Penates; others suggest that Ceres may be equated with the Greek Kore (that

"maiden"), another name for Persephone, the daughter of Demeter, with whom Demeter herself was often confounded. The worship of Demeter, or Ceres, was introduced into Rome from Sicily at the beginning of the 5th century B.C., and the first temple to her was vowed by the dictator, A. Postumius Albinus, 496 B.C. Her worship soon acquired a considerable degree of political importance. She was the goddess of the earth in its capacity of bringing forth fruits and grain. Her festival was the Cerealia (Cerialia), celebrated April 19. She is always represented as fully draped, with ears of corn and poppies in her hands and on her head a corn-measure. They sacrificed pigs and cows to her. As usual when the Romans introduced the worship of a foreign divinity into their own city, they adopted all the legends connected with that divinity, adapting them to their own mythology. Thus she was made the daughter of Saturn and Ops, and sister of Juno, Pluto, Neptune, Jupiter and Vesta. Her daughter was Persephone (q.v.). See also ROMAN RELIGION.

CERES, the name of the first asteroid discovered between the orbits of Mars and Jupiter. It was discovered by Giuseppi Piazzi, Jan. 1, 1801. Having observed it at Palermo, in Sicily, he called it Ceres, after the old tutelary divinity of that island. Under favorable circumstances it has been seen by the naked eye as a star of the seventh magnitude, but more generally it looks like one of the eighth magnitude; some observers call the light reddish and perceive a haze about the planet. Its diameter is about 500 miles.

CEREUS, sê-rê-ûs, a genus of plants of the family Cactaceae, remarkable for their singularity of form and the beauty of the flowers. *C. giganteus*, the suwarrow or saguaro of the Mexicans, is perhaps the largest and most striking of the genus. It rises to the height of 50 or 60 feet, and looks more like a candelabrum than a tree of the normal type. It occurs in Arizona and northwestern Mexico. Other notable species are *C. senilis*, the long gray bristles of which give it the appearance of the head of an old gray-haired man. *C. grandiflorus* is the night-flowering cereus, but there are others which also flower at night. *C. speciosus*, an erect plant, commonly cultivated in greenhouses, is a native of Mexico. *C. flagelliformis*, a creeper, is not unfrequently met with in gardens. The members of the genus are generally useful as cardiac agents and antipyretics. The fruits of many species are used for food.

CERIGNOLA, châ-rê-nyô'lâ, town, Italy, in the province of Foggia, 22 miles southeast from the city of Foggia. It has a college, several convents, and a hospital. The inhabitants manufacture linen; the district produces large quantities of almonds, oil, and cotton. In 1503 the Spaniards under their *Gran Capitán*, Gonzalo Fernández de Córdoba, defeated the French commanded by Louis d'Armagnac, duke of Nemours, who was slain. Pop. (1951) 51,268.

CERIGO, châ-rê-gô, (ancient CYTHERA), Island, Greece, in the Mediterranean, separated from the southern coast of the Morea by a narrow strait. It formerly belonged to the Ionian Republic of the Seven Islands, but in 1864 became part of the province of Arcadia, Greece;

area, 110 square miles. It is rather rocky and mountainous. Grain, wine, olives, and other fruits are raised. Sheep and goats constitute the chief live stock. The people are of Greek origin, and are all of the Greek Church. At an early period a Phoenician colony was founded here. Later it was successively under the control of Argos, Sparta, and Athens, and finally fell into the hands of the Romans. After submitting to Venice and then to Turkey, in 1718, it was once more assigned to Venice. It was annexed to France in 1807; two years later it was occupied by the English; after 1815 it shared the fate of the Ionian Islands. It was anciently sacred to Aphrodite (Venus), who was also called Cytherea. Pop. 9,092.

CERINTHUS, sê-rin'thûs, one of the first heresiarchs who, according to Saint Irenaeus in his work, *Against Heresies*, was contemporary with the evangelist Saint John; but Tertullian and Epiphanius refer him to the time of Hadrian. In Irenaeus' work, as also in the *Philosophumena*, attributed variously to Origen and Hippolytus, bishop of Ostia, Cerinthus is represented as an alumnus of the pagan philosophical schools of Alexandria; but he broached his heretical doctrines in Asia Minor, and there had a numerous following. The universe, he taught, is not the work of the First God, but was created by some angelic power far inferior to the supreme power. Jesus he held to be the son of Joseph and Mary, born as other men are born, but excelling all in righteousness, wisdom, and understanding. Cerinthus taught also that upon Jesus, after his baptism of John, descended the Christos from the power which is supreme over all, in the form of a dove, and that then Jesus proclaimed the unknown Father and wrought miracles; but that at the end of the passion the Christos flew away out of Jesus, and Jesus suffered, but that the Christos remained impassible, being the spirit (or breath) of God. Angels play a conspicuous part in the system of Cerinthus. Thus it was an angel, he says, that gave the law to Moses; and the Yahve of Israel was an angel. Cerinthus and his followers entertained a special animosity against Saint Paul and Saint John, and the heresiarch is credited with writing an apocalyptic book in rivalry with Saint John. He is said to have been a believer in the millennial reign of the Christ upon the earth. Modern critics consider Cerinthus a Gnostic who, in common with the Jewish Ebionites, held the belief that the Christ was a thing apart, which was with Jesus only during his life and left him at death.

CERITE, sê-rî't, a mineral occurring only at Bastnäs Västmanland, in Sweden, and containing the rare element cerium, and others of the cerium group. Its formula is not certainly known, but the mineral may be described as a silicate of the metals of the cerium group, combined with small quantities of calcium and iron. It is mostly massive or granular, but crystals belonging to the orthorhombic system are sometimes found. Cerite has a hardness of about 5.5, and a specific gravity of about 4.9. It has a peculiar and characteristic color, intermediate between clove-brown and cherry red shading off to a gray.

CERIUM, sê-rî-ûm, a metallic element be-

longing to the "rare earth" or "lanthanide series." These elements are all alike in that their two outer electron shells are the same. The atomic number of cerium is 58 and its atomic weight 140.13. Its density is 6.92, melting point 640°C., and boiling point 1400°C. Cerium was discovered independently in 1803 by Martin Heinrich Klaproth, and by Jöns Jakob Berzelius, and Wilhelm Hisinger, and was named for the then new planet Ceres. Its common oxides are Ce_2O_3 and CeO_2 , and there are both cerous and ceric salts. Cerium is the twenty-fifth in order of the abundance of the elements. It occurs along with others of the same series and is very hard to separate from them. Its chief sources are monazite sand and bastnaesite. The metal is obtained by electrolysis of its chloride, but most commonly as an alloy called "mischmetal" in which it is the chief ingredient along with other lanthanide metals. Cerium is rarely used alone, but is a minor but extremely effective ingredient of many useful substances. Cerium sulphate is a valuable analytical reagent. Only the oxalate is used in medicine. Cerium oxide is a strategic material because of its clean and efficient action in polishing optical glass. Cerium oxide adds heat resistance to glass, acts as an opacifier in enamels, and renders Seger cones luminescent. It adds to the brightness of arc carbons, and its aluminum silicate is a phosphor in fluorescent lamps. A small amount of cerium is necessary in the infrared detecting device, the metascope. Cerium oxide to the extent of only 1 per cent made the thorium of the now nearly obsolete gas mantle incandescent, but a more modern use is as an ingredient, the pyrophoric iron alloy in lighter flints. Cerium is in the electrodes of certain photoelectric cells. The metal really comes into its own in the alloy field. Added to hypereutectic cast iron it makes the graphite form in nodules with great improvement in the product. Cerium is in many stainless and tool steels. Magnesium alloys containing cerium along with zirconium or manganese have excellent high temperature properties. Cerium has a markedly beneficial effect on aluminum alloys when no more than 1 per cent is present.

CERNAUTI, chër-nà-ōōts'; -ōō'tsë, city, Soviet Union, principal city of Bukovina, Ukrainian Soviet Socialist Republic, on the right bank of the Prut, 164 miles southeast of Lvov; the German name was CZERNOWITZ. It possesses a notable university, founded in 1875, an industrial museum, and botanical garden. During the 19th century Cernauti expanded from an insignificant village into an important commercial and industrial center. Occupied by the Austrians in 1775, it passed under Rumanian sovereignty after World War I; following World War II it was ceded to Russia. Pop. (1939 est.) 109,698.

CERNUSCHI, châr-nōōs'kê, **Enrico**, Italian economist: b. Milan, 1821; d. Menton, France, May 12, 1896. He graduated at Pavia in 1842, and soon thereafter began to take a prominent part in radical political movements. Involved in the nationalist insurrections in Milan in 1848 and Rome the next year, he sought refuge in France in 1850. Settling in Paris, he acquired a large fortune as a banker and became a director of the Bank of Paris. In *Le Siècle*, of which he was principal owner, he denounced socialism so violently that he aroused the antagonism of the Commune and was compelled to leave the coun-

try in 1871. For several years he traveled widely visiting the Orient and, in 1877, the United States. He bequeathed his valuable ethnological and art collections to the city of Paris, where they were housed in the Musée Cernuschi, opened in 1898. He was an ardent advocate of bimetalism, the term for which he is said to have coined expounding his views on the subject in *Silver Vindicated* (1876). Other works included *Mécanique de l'échange* (1865); *Le bi-metallisme à quinze et demi* (1881); *Le Grand Procès de l'Union latine* (1884); *Illusions des sociétés coopératives* (1866); *Anatomie de la monnaie* (1886).

CERO, sê'rô, a large, edible fish (*Scomberomorus regale*) of the western Atlantic, and similar to the Spanish mackerel. Another species (*S. cavalla*), also called "sierra" or "king cero" is found in the southern Atlantic, and reaches double the weight of the former, often attaining 100 pounds.

CEROGRAPHY, sê-rôg'rá-fë, the art of making designs or drawings in or by means of wax, as practiced by the ancients. The art of painting in wax is known as encaustic painting (see MURAL PAINTING). The word comes from the Greek *kêros*, wax; *graphein*, to write.

CERRE, sê-râ', **Jean Gabriel**, Canadian-American fur trader: b. Montreal, Aug. 12, 1734; d. St. Louis, Mo. (?), April 4, 1805. One of the wealthiest men of his time in the West, he had a trading post at Kaskaskia, Ill., when George Rogers Clark captured it from the British in 1778, and was persuaded to provide money and provisions for Clark's men. Cerré later moved to St. Louis, and in 1780 established one of his many trading posts at what became New Madrid, Mo.

CERRO DE PASCO, sêr'rô thâ päs'cô, town, Peru, situated about 112 miles northeast of Lima, with which it is connected by road and the highest railroad in the world. It is the capital of Pasco Department, and from 1851 to 1931, when it was replaced by Huancayo, was the capital of Junin Department, out of part of which Pasco Department was created in 1944. One of the most famous mining centers in the world, Cerro de Pasco was founded in 1771 in a cold, desolate region of the Andes at an altitude of 14,208 feet. It is accordingly one of the highest inhabited places in the world; the labor for the mines must be supplied exclusively by Indians accustomed to the rarified atmosphere.

According to tradition, silver was discovered here in 1630, and until the decline in silver production late in the 19th century, its mines were second in South America only to Potosi in Bolivia. Copper succeeded silver, and Cerro de Pasco produces nearly all of that metal mined in Peru; the chief producer being the Cerro de Pasco Copper Corporation. Considerable quantities of gold, lead, zinc, and bismuth are also mined, and Mina Ragra nearby, owned by the Vanadium Corporation of America, accounts for some 80 per cent of the world's vanadium. There is a lead refinery and a copper smelter at La Oroya along the railroad to Lima. This railroad (Lima to La Oroya), a magnificent feat of engineering containing no less than 67 tunnels,

was constructed by Henry Meiggs (1811-1877), while he was a fugitive from justice in the United States. Meiggs' funds were exhausted, however, before he could bring the line to Cerro de Pasco.

CERRO GORDO, sĕr'ró gôr'thò, **Battle of**, one of the sharpest engagements of the Mexican War, fought April 18, 1847 for possession of the mountain pass called Cerro Gordo ("fat hill") between the port of Veracruz and Jalapa (or Xalapa). After the capture of Veracruz the American commander, Gen. Winfield Scott, moved his troops northwest along the National Road toward Mexico City. Some 50 miles from Veracruz this leaves the warm, humid lowlands and climbs an eastern spur of the central plateau of Mexico, seamed with ravines and thick with chaparral, and pierced by the defile of the little Río del Plan. To this defile the road, after crossing it and leaving it by a loop to the north among the mountains, returns at a ravine separating a sharp, rocky ridge called Atalaya from a conical eminence called Telegraph Hill (El Telégrafo). West of this again is the small hamlet called Cerro Gordo. On April 9, Antonio López de Santa Anna, the Mexican commander, began fortifying Telegraph Hill, and from the 12th pushed on the work with all his force; accumulating about 12,000 men, the bulk at Cerro Gordo, but neglecting to occupy Atalaya. On the 11th, Scott's vanguard came up to Río del Plan, at the foot of the plateau, and by the 17th most of his forces had arrived there. Troops under Brig. Gen. David Emanuel Twiggs occupied Atalaya, then undefended, just as a Mexican detachment advanced to do so, routed them and chased them in headlong flight half way up Telegraph Hill. The whole United States army, about 8,500, being now at hand, Scott issued orders for a general advance next day. Santa Anna's line extended from Telegraph Hill to a road at the ravine, and eastward for a mile along the heights overlooking the National Road, which ends in a precipitous rocky bluff 100 feet high; then back over three ridges terminating in rocky knolls, to the river defile. In front of the batteries and infantry, the chaparral had been cut down and piled into an abattis for several hundred feet. The Americans, on the other hand, planted powerful batteries on Atalaya, and enfiladed the Mexican right with a howitzer across the river. Scott's plan was simple, but brilliantly effective, though the impassable ground made it fall short of the full intention. Since the Mexicans expected the chief attack on their right, he resolved to make only a feint there and assuming that they expected him to move forward along the road, resolved not to do so. In the meantime he ordered the roads cleared around the hills to the north in order that by making a circuit to the National Road in the rear of the Mexicans he might cut off their retreat. On the morning of the 18th Gen. Gideon Johnson Pillow assailed the right; the artillery on Atalaya rained shot and shell with terrific effect on Telegraph Hill, the road batteries, Santa Anna's camp, and even his reserves, and the howitzer over the river added its discharge. Twiggs, Brig. Gen. James Shields and Maj. Gen. William Jenkins Worth, with Col. Bennet Riley, then moved along the circuit until they were on the north flank of Telegraph Hill, at first out of sight, then in full range of the Mexican fire. Santa Anna detached part of the

forces on Telegraph Hill to drive them back; then Harney from Atalaya swept over the crest and down the side, up Telegraph Hill until within 200 feet of the batteries and below their range. There he reformed and in one final charge utterly routed the Mexicans, at the same time turning the forces on the hill against the main body of Mexicans at Cerro Gordo. The entire right, its retreat cut off, threw down its arms and surrendered. The main body broke up in a panic, as the fugitives from Telegraph Hill rushed among them and the guns from that quarter cut them down, and fled wildly down the craggy slopes and to the defile, and westward along the road. The Mexicans lost 1,000 or 1,200 in killed and wounded; about 3,000 prisoners, including 5 generals, and 299 other officers; 43 guns and 3,500 small arms. The Americans lost 63 killed and 368 wounded. The victory laid open the road nearly to the Mexican capital.

CERRO LARGO, sĕr'ró lăr'gò, **department**, Uruguay, in the northeast of the republic. It is well watered, with large savannahs and forests. The inhabitants are chiefly engaged in raising cattle, wheat and other grains. The capital is Melo. Area 5,764 square miles; pop. (1950 est.) 97,256.

CERTALDO, châr-tâl'dò, **commune**, Italy, in Firenze (Florence) Province, Tuscany. It is situated partly on a height, and partly on a flat along the right bank of the Elsa, 18 miles southwest of Florence. The town is an agricultural center, marketing wines and oil; and has a medieval castle rebuilt in the 15th century. It came under Florentine influence in 1198, and was ruled by that city during and after the 13th century. Another building of interest is the Boccaccio House, with a small museum; Giovanni Boccaccio having lived in Certaldo toward the end of his life. Pop. (1940) 12,094.

CERTIORARI, sŭr-shĭ-ô-râ'ri, **in law**, a writ issuing from a superior court to call up the record of a proceeding in an inferior court, or before a body or officer exercising judicial power, that it may be tried or reviewed in the superior court. This writ is usually obtained on complaint of a party that he has not received justice, or that he cannot have an impartial trial in the inferior court or body. It is now largely superseded by the appeal.

CERULEUM, sĕ-rōō'lĕ-ŭm, or **CERULEAN**, sĕ-rōō'lĕ-ăn, a light greenish-blue pigment, in chemical essence a cobaltous stannate. It is both stable and light-fast, and is made by precipitating cobaltous chloride with potassium stannate and heating with a mixture of silica and calcium sulphate.

CERULLI, châr-rōō'lĕ, **Vincenzo**, Italian astronomer: b. Teramo, Abruzzi e Molise, April 20, 1859; d. Merate, Lombardy, May 30, 1927. He was educated at Rome and the observatories of Bonn and Berlin, and for a time was astronomer at the Gregorian University in Rome. In 1892 he founded the observatory at Collurania, near Teramo, of which he became director. He was especially known for his work on Mars and Venus, and his discovery of the planetoid (704) Interamnia. He was a corresponding member of important scientific academies and of

the Italian Astronomical Society. He was the author of two works on Mars and three volumes of publications of the Collurania Observatory, and was a contributor to *Astronomische Nachrichten*.

CERUMINOUS GLANDS, sê-rōō'mī-nūs, the glands of the passageway of the external ear. They secrete cerumen, or earwax, which lubricates the passage to the eardrum. The secretion is extremely bitter and is of a yellowish-brown color. The wax is insect repellent and prevents gnats and other small insects from entering the ear. Occasionally the wax hardens within the passage and becomes attached to the drum itself so that a temporary deafness is produced. This is easily overcome by cleansing the ear passage with a pressure syringe. It is inadvisable for a person to remove the wax himself by means of ear spoons or other instruments, since injury to the drum membrane may result.

HAROLD WELLINGTON JONES, M.D.

CERUSSITE, sêr'ū-sīt, a native lead carbonate, $PbCO_3$. The crystals are orthorhombic, usually in stellate twins, but it is also found in massive, earthy, and stalactitic forms. It is very brittle, has a hardness of 3 to 3.5, and a specific gravity of 6.5. It is translucent, with an adamantine luster. The usual color is white or light gray, but inclusions may make it black, green, or blue. Common as an alteration product of galena, it is an important ore of lead, and frequently contains silver. Fine crystals have been found at Phoenixville, Pa. It is mined in Colorado, Idaho, Arizona, and Utah. Other important localities are Ems, Germany; Sardinia; Spain; Tsumeb, Southwest Africa; and Broken Hill, New South Wales.

CERUTTI, chā-rōō'tē, **Giuseppe Antonio Gioacchino**, French Jesuit theologian: b. Turin, Italy, June 13, 1738; d. Paris, France, Feb. 3, 1792. He was one of the most eminent professors in the Jesuit college at Lyon and his *Apologie de l'institut et de la doctrine des Jesuites* (1762) attracted much attention. He had already published two discourses upon the means of preventing duels, and on the reasons why modern republics have not reached the splendor of the ancient.

He was at Paris in 1789 when the Revolution broke out. Abandoning his former principles, he became one of the most zealous supporters of the new order of things. He was intimately connected with Mirabeau, and labored much for him. He also published with two others a paper called *La Feuille villageoise* for the purpose of keeping villagers informed of the news of the day, and several pamphlets, among them *Mémoire pour le peuple français*. In 1791 he was a member of the legislative assembly. Some time after, he delivered in the church of Saint-Eustache a funeral oration upon Mirabeau.

CERVANTES, sêr-vān'tās, municipality, Philippine Islands, in the eastern part of Ilocos Sur Province in northwestern Luzon. It is on the left bank of the Abra River. Pop. (1948) 4,346.

CERVANTES SAAVEDRA, thêr-vān'tās sâ-ā-vā'thrā, **Miguel de**, Spanish novelist, playwright, and poet: b. Alcalá de Henares, Spain, 1547; d. Madrid, April 23, 1616. He was the fourth child of seven in the family of a deaf,

impoverished surgeon, Rodrigo de Cervantes, whose poverty forced him to move around from town to town. When scarcely seven, Cervantes was in Madrid studying under the humanist Juan López de Hoyos, who encouraged him to write poetry. After 1569 he traveled widely in Italy as valet of Giulio Acquaviva, the brilliantly educated cardinal, in whose company he learned more than in any university. After a while Cervantes enlisted as a soldier in the forces of Diego de Urbina, and on Oct. 7, 1571, took part in the naval Battle of Lepanto. Despite a high fever, he fought as doughtily as any of the men in his galley, the *Marquesa*, and was thrice hit by harquebus shots, one of which permanently maimed his left hand. On recovering from his wounds, he continued his heroic exploits in Lope de Figueroa's battalion at Navarino, Tunis, and La Goleta. He returned to Naples and was granted leave, sailing for home on Sept. 20, 1575 with important letters—one from Prince John of Austria to Philip II—attesting to his valor and gallantry. However, the galley *Sol* in which he was traveling was captured by pirates, and he was taken to Algiers where he remained for five torturous years of slavery and imprisonment. However, during this period he had opportunity to compose some verses. On four occasions he tried to escape, once inciting his

Miguel de Cervantes Saavedra

fellow Christian captives to rebellion. He was finally ransomed by the Trinitarians Fray Juan Gil and Fray Antón de la Bella in September 1580. Little is known of his years in Spain immediately after his homecoming except that in 1585 appeared Part 1 of *La Galatea*, a pastoral novel which, despite his repeated promises, was never completed. As a work of prose fiction it is, like the Italian and Italianate models he was imitating, elegant, highly artificial, and very much a *roman à clef*. He also composed several plays, visited Portugal and Oran (1581) on short missions, and had an affair with a certain Ana Franca de Rojas, who bore him a daughter, Isabel.

In 1584 Cervantes had married Catalina de Palacios Salazar y Vozmediano, a member of an ancient but impoverished family. Compelled to look for lucrative activity, he tried his hand at writing for the stage. To this period may be ascribed *El trato de Argel* and the powerful tragedy *La Numancia*. In 1587 he began his trying journeys as tax collector through Andalusia and La Mancha, gathering oil and grains for the Invincible Armada. On one occasion he was excommunicated for appropriating grain belonging to the Cabildo of Sevilla; on another, a Portuguese banker, Simón Freire de Lima, went bankrupt and lost a considerable sum for which Cervantes was held responsible. Twice he found him-

self in a Sevillian jail—in 1597 and again in 1602. Perhaps during these periods of relative quiet he came upon and gestated the idea of *Don Quixote* (*Don Quijote de la Mancha*).

At the beginning of the 17th century, when Philip III moved his court to the city of Valladolid, Cervantes was living there with his sisters Andrea and Magdalene, his illegitimate daughter Isabel Saavedra, and his niece Constanza de Ovando. On June 27, 1605, a gentleman named Gaspar de Ezpeleta was wounded in front of their house and died without revealing his killer. The Cervantes family was thrown into jail, but soon released when nothing could be proved against them.

Part 1 of *Don Quixote* appeared in 1605, and Part 2 in 1615; *Novelas ejemplares* (*Cautionary Tales*) in 1613; *Viaje al Parnaso* (*Journey to Parnassus*) in 1614; *Ocho comedias y ocho entremeses nuevos* (*Eight New Comedies and Interludes*) in 1615; and *Los trabajos de Persiles y Sigismunda*, a posthumous work, in 1617. Thus clearly his richest literary crop belongs to the last decade of his existence, the work of a man over sixty, and as such bears the stamp of ripe wisdom, of graciousness, and generous love. These last years Cervantes spent in Madrid where, before his death, he joined a religious order, La Venerable Orden Tercera (Tertiaries of St. Francis), in the robes of which he was buried.

Cervantes became immortal through *Don Quixote*, one of the world's greatest literary monuments. In this satire of the romances of chivalry Cervantes gathered not only the rich experiences of his life, but, an indefatigable reader endowed with a retentive memory, he rendered as well brilliant echoes of Spanish, Italian, and Latin culture. His knowledge of the literature dealing with knight errantry was inexhaustible; his handling of dialogue compares with the best of the playwrights of the Golden Age; and his familiarity with his native country enabled him to present a broad and most illuminating fresco of the Spanish society of his epoch.

Beneath the humorous surface of Cervantes' book lies a deep satire, tragic at times, of the idealistic excesses and follies of chivalrous Spain, whose decline Cervantes seems, almost uncannily, to intimate. His main characters, Don Quixote and Sancho Panza, are universal symbols; their exploits and philosophies influenced innumerable writers, and have led to the production of a vast critical body. Considering their craftsmanship and consummate artistry *The Cautionary Tales* (*Exemplary Novels*) are equally mature and brilliant and they had, too, a wide repercussion upon the literature of England and the Continent.

Although Cervantes was essentially a poet, his formal achievement in verse never soared to the heights or attained the lyrical perfection of his many gifted contemporaries. As a playwright he is still remembered for his historical tragedy in verse *La Numancia* and for his amusing *Interludes*, masterfully translated in 1948 by S. Griswold Morley.

With the exception of J. Ormsby's version (1885), the most readable English translations of *Don Quixote* are the ones by Samuel Putnam (New York 1949) and, especially, J. M. Cohen (Penguin Books 1950). A comprehensive work in English on Cervantes and his influence is A. Flores and M. J. Benardete, eds., *Cervantes Across*

the Centuries (New York 1947). See also DON QUIXOTE; EXEMPLARY NOVELS.

ANGEL FLORES,
Professor of Spanish Literature, University of Wisconsin.

CERVANTITE, sŭr-văn'tit, or **ANTI-MONY OCHER**, is native antimony oxide, $Sb_2O_3 \cdot Sb_2O_5$. It usually occurs in crusting stibnite and other antimony ores. It has a pale yellow color and greasy luster.

CERVERA Y TOPETE, thër-vä'rä ê tô-pä'tä, Pascual (CONDE DE JEREZ, hâ-râth', MARQUÉS DE SANTA ANA, sän'tä ä'nä), Spanish naval officer: b. Medina-Sidonia, Cádiz, Spain, Feb. 18, 1839; d. Puerto Real, April 3, 1909. During the period 1848–1851 he was educated at the naval academy at San Fernando. He was made a first lieutenant in 1859 and participated in naval operations on the Moroccan coast during the campaign of 1859–1860. In 1868 he was promoted captain and subsequently admiral. He played an important role in the first Cuban revolt (1868–1878) when he succeeded in blockading the ports and preventing the landing of filibusters.

In 1891 he went to London as head of the Spanish commission at the naval conference, and in 1892 was minister of marine. After the outbreak of the Spanish-American War in 1898 he commanded the fleet sent against the American squadron in Cuban waters. He took refuge in the inner harbor of Santiago de Cuba, and when he attempted to escape on July 3, under orders from his superiors, his entire fleet was destroyed by the American squadron. Admiral Cervera and his surviving officers were sent to Annapolis, Md., as prisoners of war, but soon afterward were released and allowed to return to Spain. In 1901 he was made vice admiral, and in 1902 chief of staff of the Spanish Navy.

CERVIDAE, sër'vî-dē, the deer family, a group of ruminant ungulates, having as its most noticeable characteristic the presence in the males of branched appendages to the skull, called antlers. These are lacking in certain species which are related, however, to the antlered deer. Only among reindeer do the females have antlers (q.v.). Other peculiarities of the family are the absence, except in *Moschus*, of a gall bladder and the usual presence of face and foot glands.

The approximately 35 species occurring in northwest Africa, Eurasia, and the Americas may be divided into five subfamilies. The Moschinae, containing only the musk deer (q.v.) of East Asia, are hornless and lack several other characteristics of other Cervidae. The Hydropotinae, including only the Chinese water deer, are also hornless, but otherwise like typical deer. The Muntiacinae of East Asia comprise chiefly the muntjacs (q.v.). Short antlers are borne on long bony pedicels. All three of these subfamilies have canine tusks especially well-developed in males. The remaining deer, in which the males lack canine tusks and bear the antlers on short pedicels, are divided into two subfamilies. The Cervinae

contain most of the Old World deer together with the wapiti (q.v.), while the *Odocoileinae* contain the remaining American deer as well as the Old World elk, reindeer, and roe deer (qq.v.).

The earliest known deer, the fossil *Eumeryx* and *Amphitragulus*, were small creatures somewhat similar to the living *Hydropotinae* in being totally hornless. Not until the middle of the Miocene have deer been found with antlers. Later came deer with branching horns, culminating in a European species, now extinct, the giant Irish elk, whose palmated antlers spread 10 to 12 feet; it was actually a huge fallow deer. See also **DEER**.

KARL KOOPMAN.

CERVIN, Mont, French name for the mountain in Switzerland better known as the Matterhorn (q.v.).

CERVOLLE, sër-völ, or **CERVOLE**, Armande de, French bandit chief, surnamed "The High Priest." He was taken prisoner with King John at the Battle of Poitiers in 1356, and after being ransomed, plundered the south of France with a band of troopers (*rouitiers*), and exacted tribute from Innocent VI at Avignon. He served for a time under the Dauphin, and pillaged Burgundy, Champagne, Alsace, and Lorraine. In 1365 he was made chamberlain to Charles V, and the next year he was murdered.

CESALPINO, chā-zāl-pē'nō, **Andrea** (Latin *ANDREAS CAESALPINUS*), Italian philosopher, botanist, and physician: b. Arezzo, Italy, 1519; d. Rome, Feb. 23, 1603. He studied medicine at the University of Pisa, where he secured a doctor's degree in 1551. In 1555 he was appointed professor of *materia medica* at Pisa, and also director of the university's botanical garden. He was the author of a valuable work, *De Plantis* (Florence 1583), in which he classified plants by their parts of fructification. To this work Carolus Linnaeus, Bernard de Jussieu, and other subsequent botanists were greatly indebted for their ideas of botanical classification. In 1592 he removed to Rome to become physician to Pope Clement VIII. He propounded in his *Daemonum investigatio peripatetica* (1580) the theory of the circulation of the blood, afterward adopted and demonstrated by William Harvey. Other works included *Quaestionum medicarum* (1593); *De Metallicis* (1596).

CESAR BIROTTEAU, a novel of French business life, published in 1837 by Honoré de Balzac (q.v.). It is, perhaps, the most notable in a noteworthy group of tales known under the general title of *La Comédie Humaine*. It deals with business venture and the chicanery of unscrupulous finance, with the cumulative entanglements of debt, and the legal snares of usurious oppression. In this novel these are viewed from the point of view of a prosperous tradesman, with chivalrous standards of commercial honor, whom success in his own field betrays into ventures in unfamiliar regions where he falls among thieves, men whom he thought he had special reason to trust. It is, Balzac says in his preface, "the obverse of a medal whose reverse is *La Maison Nucingen*," which deals, somewhat less genially, with the same theme from the side of the exploiters of men of too credulous probity. César, a brother of

Balzac's memorably unfortunate Curé de Tours, had prospered as a manufacturing perfumer during the consulate and the empire, though his relations to militant royalists had brought him a wound in connection with the conspiracy of Vendémiaire, 1795, which seemed to give him a title to the aid of royalist sympathizers after the Restoration. One of these was the very unscrupulous and successful Baron Nucingen. Du Tillet, once Birotteau's headclerk and a betrayer of both his domestic and his mercantile confidence, but now a financial shark and confederate of Nucingen for his baser needs, interests Birotteau, at a moment when his ambition reaches full bloom in a nomination as chevalier of the Legion of Honor, in a speculation and in imprudent expenditure by which his wealth becomes theirs and he a bankrupt debtor. By heroic exertion, four years' persistent labor, and scrupulous economy, aided by Popinot, another type of industrialist, who was later to marry Birotteau's worthy and charming daughter Césarine, the debtor discharges the whole of his liabilities, dying from the relaxing of the strain immediately after his solemn rehabilitation and the restoration of his commercial honor and coveted decoration by the courts. The story is less to be commended as a whole than for its portrayals of character, especially of the two druggists, the generous and loyal Popinot and the smug materialist Matifat, of the gentleman-scoundrel Du Tillet, and the ingenuously gracious Césarine, and most of all for its minute pictures, drawn it may well be from Balzac's own frequent memories, of the mental and moral tortures of César in his cumulating commercial embarrassments. There are four English translations.

BENJAMIN W. WELLS.

CESARI, chā'zā-rē, **Giuseppe**, CAVALIERE D'ARPINO (called IL GIUSEPPINO), Italian painter: b. Rome, 1568?; d. there, July 3, 1640. The son of a native of Arpino, he was widely esteemed for his religious paintings, which tended more toward idealism than realism. In the year 1585 he received his first commission from Pope Gregory XIII, who appointed him one of the group employed in the decoration of the Vatican. No less than five popes honored him. Clement VII created him Cavaliere de Cristo. In style, he was one of the later mannerists. The finest examples of his work include frescoes in the Capitol, at Rome, and in the Borghese chapel of Santa Maria Maggiore; the huge *Ascension* in the Church of Saint John Lateran; frescoes of the Olgisti Chapel, in Santa Prassede; designs for mosaics in the dome of Saint Peter's. A number of his smaller pictures may be found in various galleries. These include *Persens* and *Andromeda* (Metropolitan Museum of Art, New York); *Adam* and *Eve Expelled from Paradise* (Louvre, Paris); a self-portrait (Uffizi Gallery, Florence). His works—in fresco and oil—display lively imagination, and great vigor in execution, although the broadness of his treatment has often been subjected to severe criticism by the more formal stylists of later periods.

CESARINI, chā-zā-rē'nē, **CARDINAL Giuliano** (known as **CARDINAL JULIAN**), Italian ecclesiastical diplomat: b. Rome, 1398; d. Varna, Bulgaria, Nov. 10, 1444. Educated at the University of Perugia, he became professor of jurisprudence at Padua. He was counselor to Pope Martin V,

who made him a cardinal in 1426 and bishop of Frascati. Failing to coerce the Hussites, at the Council of Basel, of which he was president from 1431, he tried to settle their differences with Pope Eugenius IV. From 1438 he took part in the negotiations carried on with the Eastern Church, and Eugenius IV sent him as legate to Poland to stir up a crusade against the Turks. He met his death at the Battle of Varna (Stalin).

CESAROTTI, chā-zā-rōt'tè, Melchiorre, Italian poet: b. Padua, May 15, 1730; d. there, Nov. 4, 1808. He taught rhetoric at Padua, and in 1762 he went to Venice, publishing in 1763 a translation into Italian of *The Poems of Ossian* by James Macpherson. Besides translations, his works included *Saggio sulla filosofia della lingue* (1785) and *Pronea* (1807); the latter was a poem in praise of Napoleon, who made him knight of the Iron Crown. Giuseppe Barbieri completed the 40-volume edition of his works (Pisa 1800-1813).

CESENA, chà-zā'nā, city, Italy, in the Province of Forlì, the episcopal see of Emilia, on the Savio, 52 miles southeast of Bologna. Notable buildings include a library built in 1452 for Domenico Malatesta Novello. In a church of the Capuchins is one of the finest paintings by Guercino (Giovanni Francesco Barbieri). Hemp, vegetables, wine, sulphur, and silk are items of trade. Cesena was the birthplace of Popes Pius VI and VII. In 1357, under Maria Ordelaaff, wife of the lord of Forlì, the town made an unsuccessful defense against the papal troops led by Gil Alvarez Carillo de Albornoz. It was pillaged in 1377 by Cardinal Robert of Geneva (later the antipope Clement VII). Pop. (1948) 70,212.

CESIUM, a metal of the Ia group known as the "alkali metals." The name is derived from a Latin word meaning "light blue," and refers to characteristic blue lines in its spectrum. Cesium was the first element to be discovered by the aid of the spectroscope, this being accomplished by R. W. Bunsen and G. R. Kirchhoff in 1860. Cesium is somewhat more abundant in the earth's crust than silver. Although the amount present in carnallite is small, cesium has been produced in quantity from the residues of the potash industry in Europe. Several extensive deposits have been found in the United States, the most noteworthy being in the Black Hills of South Dakota. The most important source of cesium is pollucite, whose mineralogical formula is $2\text{CsO} \cdot 2\text{Al}_2\text{O}_3 \cdot 9\text{SiO}_2 \cdot \text{H}_2\text{O}$. Cesium may be extracted from its ores by mineral acids, and isolated in the form of double chlorides of lead or antimony. The metal may be produced by reduction of the carbonate or hydroxide by magnesium or aluminum in a current of hydrogen. It is a silvery white metal melting at 28.45°C . and boiling at 630°C . Its specific gravity at 0°C . is 1.903. Cesium is extremely reactive, forming oxides in dry air, igniting in moist air, and liberating hydrogen from water with explosive violence. Cesium has an atomic weight of 132.91 and an atomic number of 55. The salts of cesium resemble those of the other alkali metals. There are a number of isotopes of cesium resulting from nuclear reactions, but only the 133 isotope is found in nature. Cesium is the heaviest of the alkali metals.

The chief industrial use of cesium is in vacuum tubes. Because of its extreme reactivity, it removes the residual gas in evacuated tubes. Cesium metal is produced in the tube by the action of calcium on the chloride, high-frequency current furnishing the necessary heat. Cesium, alloyed with other metals such as antimony, bismuth, and gold, has the property of releasing electrons under the influence of light, and is thus employed in photoelectric tubes.

CESNOLA, chāz-nō'lā, Luigi Palma di, Italian-American army officer and archaeologist: b. Rivarolo, Italy, July 29, 1832; d. New York, New York, Nov. 21, 1904. From 1849 until 1859 he served in the Crimean War. Going to the United States in 1860, he taught in New York City until the Civil War, when he joined the Union forces as a major. Captured at Aldie, Va., in 1863, he was exchanged the next year. In 1865 he was brevetted a brigadier general and was naturalized. For the next 11 years he was United States consul at Cyprus, where he conducted archaeological researches. His collection of antiquities was purchased in 1873 by The Metropolitan Museum of Art, New York; from 1879 until his death he served as secretary and director of that institution.

CESPEDES, sās'pā-thās, Carlos Manuel de, Cuban revolutionist: b. Bayamo, April 18, 1819; d. March 22, 1874. In 1843 he was in the conspiracy led by Juan Prim y Prats and was banished from Spain. After returning to Cuba, he led the armed revolt (1868) which began the Ten Years' War. In 1869 he was elected president of the republic set up by the revolutionists, but was deposed in 1873. He was killed in a skirmish with the Spaniards.

CESPEDES, thās'pā-thās, Pablo de, Spanish painter, sculptor, architect, and poet: b. Córdoba, 1538; d. there, July 26, 1608. After studying at the University of Alcalá de Henares, he went to Rome, where he studied under Federigo Zuccaro the works of Raphael, Michelangelo, and others. Returning to Spain in 1577, he was made a canon of Córdoba Cathedral, and from that time he resided alternately in his native town and in Seville. One of his most celebrated paintings is a *Lord's Supper* in Córdoba Cathedral.

CESPEDES Y QUESADA, Carlos Manuel de, Cuban statesman, son of Carlos Manuel de Céspedes (q.v.); b. New York, New York, Aug. 12, 1871; d. Havana, Cuba, March 28, 1939. He held many diplomatic and government posts, serving in Rome, Athens, and Buenos Aires, and was minister to the United States from 1913 to 1922. When Gerardo Machado was overthrown in August 1933, Céspedes became provisional president of Cuba from August 12 to September 5, but was forced to resign after a coup d'état by students and the army. He was ambassador to Spain (1934-1936), after which he retired.

CESSIO BONORUM, sēsht'ō bō-nō'rūm ("surrender of goods"), a process by which, according to the law of Scotland, a debtor against whom a warrant of imprisonment was issued, after being charged to pay his debt, was entitled to be free from imprisonment, if innocent of fraud, on surrendering his whole estate to his

creditors. This procedure avoided infamy, and the debtor could not be deprived of the bare necessities of life. Since the abolition of imprisonment for debt a debtor may be compelled to make *cessio bonorum* at the instance of a creditor. Any property accumulated after this surrender is liable to attachment so long as the debt is not wholly paid. Both the phrase and essentially the same procedure occur in Roman law.

CESTI, chās'tè, Marc' Antonio, Italian composer; b. Arezzo, Italy, Aug. 5, 1623; d. Florence, Oct. 14, 1669. Maestro di capella at Florence and vice kapellmeister at Vienna, his operas include *Dori* (1660) and *Il pomo d'oro* (1667).

CESTIUS, sēs'ti-ūs, the name of a plebeian gens of Rome, of which two memorials have been preserved. One of them is a bridge connecting the island of the Tiber with the right bank of that river. The other, the Pyramid of Cestius, is the tomb of Gaius Cestius, Roman praetor and tribune of the people, who lived during the 1st century B.C. Standing at the gate of San Paolo, partly within and partly without the walls of Aurelian, this pyramid is about 125 feet high and 95 feet broad at its base. It is built of bricks, encased with blocks of marble.

CESTODA, sēs-tō'dà, or **CESTOIDEA**, sēs-toi'dè-à, or tapeworms, a class of the phylum Platyhelminthes. The class is characterized by an elongate, ribbon-like, usually jointed body. The segments, or proglottids, contain complete sets of reproductive organs. After transfer to the first (primary) host, the cysticercus, or bladder worm, grows into a chain.

Cestodes are parasitic in the various types of vertebrates only, though some bladder worm stages occur in worms, crustacea, and insects of various sorts. In the rare monozoic cestodes (Cestodaria), the simple body contains only a single set of sex organs; in the polyzoic cestodes, there are many such sets. The latter group contains five orders: Pseudophyllidea, Tetrphyllidea, Diphyllidea, Tetrarhynchidea (Trypanorhyncha), and Cyclophyllidea. The fish tapeworm of man falls in the first order and all the others from the human host in the last. Some zoologists classify Cestoda and Cestodaria as the two subclasses of the class Cestoidea. See also **PLATYHELMINTHES**; **TAPEWORM**.

CESTRACION, sēs-trā'shī-ōn, a genus of primitive sharks, also known as *Heterodontus*, of which the best known species is the Port Jackson shark of Australia (*C. philippi*). Four species are known, varying in length from four to five feet. They feed mainly on various kinds of mollusks. The family Cestraciontidae, though now represented by a single genus of four species, was very abundant in the earlier geological periods.

CESTRUM, sēs'trūm, a genus of the Solanaceae or Nightshade family. Tender shrubs, native in Central and South America, popular in temperate North America as greenhouse plants, and grown in the open in Southern California and elsewhere in the South. The flowers are tubular, in axillary or terminal clusters, red, yellow, greenish or white, and often very fragrant. *Cestrum nocturnum*, known popularly as night-blooming jessamine (jasmine), is a large shrub of

the West Indies. Its small greenish-white to cream-colored flowers give off at night a fragrance so penetrating that a small cluster of flowers will scent a large room. A similar but smaller shrub is *C. parqui* from Chile, the hardiest of the species. *C. diurnum*, the largest of these three species, has white flowers and is called day jessamine because it blooms in the daytime.

Consult Bailey, L. H. and E. Z., *Hortus Secundus*, p. 164 (New York 1947); also Negebauer, E. M., *Horticulture*, 30:142, 143 (Boston 1952).

ARTHUR H. GRAVES.

CESTUI QUE TRUST, sēs'twè kē trūs in law, the person for whose benefit a trust is created. In modern terminology, such a person is often described simply as a "beneficiary." Sufficient identification of the *cestui que trust*, or beneficiary, is generally an essential element in the creation of a trust, except a charitable trust. It is not necessary that the beneficiaries be in existence at the time a trust is created, but a trust cannot be created in favor of a person who is dead. There may be one or more beneficiaries, and the creator of the trust may himself be one of the beneficiaries or the sole beneficiary. In general, a person or corporation having capacity to take and hold legal title to property has capacity to be the beneficiary of a trust of such property.

RICHARD HIRSHBERG.

CESTUS, sēs'tūs (Lat. girdle), a band, or zone, said to have been worn by Aphrodite or Venus, and endowed with the power of exciting love toward the wearer. The following is Pope's translation of Homer's description of it:

In it was every art and every charm
To win the wisest, and the coldest warm—
Fond love, the gentle vow, the gay desire,
The kind deceit, the still-reviving fire,
Persuasive speech, and more persuasive sighs,
Silence that spoke, and eloquence of eyes.

CESTUS, or **CAESTUS**, the boxing glove of the Grecian and Roman pugilists. It consisted of thongs or bands of rawhide or leather, fastened to the hand and reaching to the wrist. It was afterward enlarged so as to reach up to the elbow and loaded with metal to increase the weight of the blow. The combat with the ordinary unloaded cestus was not more dangerous than a common modern boxing match. Theocritus' *Idyll* (book XXI) and Virgil's *Aeneid* (book v, p. 362) describe one of these combats.

CETACEA, sê-tā'shê-à, an order of mammals whose structure is so modified as to render them fit for an aquatic life. The whalebone whales, the toothed whales (the porpoise, narwhal, etc.), and the extinct zeuglodon represent the leading divisions of the group. The body is fish-like in form, the head passing gradually into the trunk, which tapers posteriorly and ends in a bilobate caudal fin which is placed horizontally, not as in the fishes, vertically. The posterior limbs are wanting, and the anterior are converted into broad paddles, or flippers, consisting of a continuous sheath of the thick integument, within which are present representatives of all the bones usually found in the forelimbs of mammals, but they are not movably articulated, so that the paddle moves like a solid oar. The fishlike aspect is further increased by the presence of a dorsal fin; but this is a simple fold of integument

and does not contain, as in fishes, any bony spines. The vertebrae of the neck, seven in number, are united more or less to each other, so that in some they form a single solid piece. The right whale and its allies have no teeth in the adult state, their place being taken by the triangular plates of balen, or whalebone, which are developed on transverse ridges of the palate. But the fetal whales possess minute teeth, which are very soon lost. The porpoises, etc., when they possess teeth in one or both jaws, have them numerous and conical in form; they have no milk predecessors. The stomach is divided into several chambers, but these are not, as in ruminants, connected directly with the gullet; they are rather appendages of the pyloric portion of the organ.

The arrangement of the respiratory and circulatory systems, which enables the Cetacea to remain for some time under water, is interesting. The nostrils open directly upward on the top of the head and are closed by valvular folds of integument, which are under the control of the animal. When the animal comes to the surface to breathe it expels the air violently, and the vapor it contains becomes condensed into a cloud; if the expiration commences before the mouth of the spiracle, or blowhole, is above the surface, a little water may be blown up like spray but no water from the mouth is thus discharged, for the soft palate firmly embraces during life the upper end of the larynx, so that the gullet is divided into two narrow passages, while the lungs have a continuous passage to the exterior. The blood vessels, especially those of the thorax and spinal canal, break up into extensive plexuses, or networks, in which a large amount of oxygenated blood is delayed, and thus the animal is enabled to remain under water, the necessity for changing the air in the lungs being diminished.

Fossil Cetacea.—Bones of cetaceans, mostly allied to the living species, are found in the marine sediments of the Tertiary and Quaternary ages, and are occasionally dredged up from deep-sea deposits. The hard and heavy carbonates are especially apt to be preserved as fossils. The Zeuglodon and Squalodon of the Eocene epoch represent a peculiar primitive group of cetaceans with two-rooted teeth. Very little is known of the evolution of this order of mammals. The Tertiary deposits of Patagonia are supposed to be rich in material bearing on the evolution of the Cetacea.

Classification of Cetacea.—The suborders of cetacea are as follows:

(1) **MYSTACOCETI**—cetaceans with whalebone. Its families include Balaenopteridae—rorquals and other great whalebone whales; Balaenidae—right whales and the pygmy whale (genus *Kogia*).

(2) **ODONTOCETI**—cetaceans with teeth. Its families include Physeteridae—sperm whales; Ziphiidae—beaked whales; Delphinidae—dolphins, porpoises, white whales, and killer whales; Platinistidae—river dolphins; and the extinct Squalodontidae.

(3) **ARCHAROCETI**—containing the extinct family Zeuglodontidae.

See also **WHALE** and the names of the various groups and species of cetaceans.

CETATEA ALBA. See **BELGOROD-DNESTROVSKI**.

CETEWAYO or **CETYWAYO**, sèt-è-wá'ò or kèt-è-wá'ò (Zulu, KETCHWAYO, kè-chwá'yò), king of the Zulus: b. about 1836; d. Ekowe,

Zululand, Feb. 8, 1884. He shared sovereignty over the Zulus with Panda, or Umpande, his father, from 1857 until the latter's death in 1872. The British government then recognized him as sole ruler, but because of his lawlessness war ensued early in 1879. He defeated a British force on Jan. 22, 1879, at Isandhlwana, or Isandula, near the Buffalo River, about 10 miles from Rorke's Drift. His Zulus were routed at Ulundi on July 4, 1879, and he was captured on Aug. 28. In August 1882, after living in exile in Cape Colony, he was taken to London, and on Jan. 29, 1883, he was reinstated as ruler over a portion of his kingdom. Soon, however, he was attacked by rival chiefs, and within less than a year he was compelled to seek protection of the British in the native reserve. There he died.

CETHEGUS, sê-thê'gûs, **Gaius Cornelius**, Roman statesman: d. Dec. 5, 63 B.C. An accomplice in Catiline's conspiracy to assassinate the consuls, he was condemned by the Senate and executed at the instigation of Cicero.

CETHEGUS, Marcus Cornelius, Roman general and politician: d. 196 B.C. He became curule aedile in 213 B.C., censor in 209, and consul in 204. In 203, as proconsul in Cisalpine Gaul, he was successful in driving the Carthaginian army of Hannibal's brother Mago from Italy. He was known as a persuasive orator.

CETINA, thâ-tê'na, **Gutierre de**, Spanish lyric poet and soldier: b. Seville, Spain, c.1520; d. Los Angeles, Mexico, c.1570. After fighting in Italy and Germany under Holy Roman Emperor Charles V, he returned to Seville in 1545 but shortly went to Mexico, where he resided until his death. His madrigal *Ojos Claros Serenos* was in the style of Petrarch. Many of his sonnets were written under the name of Vandalio.

Consult Withers, A. M., *The Sources of the Poetry of Gutierre de Cetina* (London 1923).

CETINJE, tsê-tê-nyê, town, Yugoslavia, in Montenegro Republic, about 25 miles west-southwest of Titograd (formerly Podgorica), situated on the lower slopes of Mount Lovcen and connected by road with Titograd and with the Adriatic seaport of Kotor (formerly Cattaro). Founded in 1484 by the Montenegrin ruler Ivan Crnojević (Ivan the Black) as a bulwark against the Turks, Cetinje was the capital of the former kingdom of Montenegro until Montenegro was absorbed by the kingdom of Yugoslavia after World War I. The town contains a fortified monastery established in 1478, the tombs of many Montenegro rulers, and the royal palace, now a museum. It was sacked and burned by Turkish invaders in 1683, 1714, and 1785. It was replaced by Titograd in 1946 as capital of Montenegro Republic. Pop. (1948) 9,109. See also **MONTENEGRO**.

CETTE. See **SÈTE**.

CETUS, sê'tûs (Lat. whale), a large constellation, lying on both sides of the celestial equator, but mainly on the southern. Ptolemy (Claudius Ptolemaeus) included it in the list of constellations in his *Almagest*. It is bounded by Pisces, Aries, Taurus, Eridanus, Fornax, Sculptor, and Aquarius. In Greek mythology, Cetus was the sea monster from which Perseus rescued Andromeda. Its brightest star is Deneb Kaitos (β

Ceti), of +2.24 magnitude; but the most famous is Mira (o Ceti; also known as Omicron), a long-period variable, discovered by David Fabricius in 1596.

CETYL, sět'il, a chemical radical corresponding in structure to the ethyl compounds. It is formulated as $C_{16}H_{33}$. Its compounds are derived from spermaceti and beeswax.

CEULEN, kù'lën, or **KEULEN**, Ludolph van, Dutch mathematician: b. Hildesheim, Jan. 28, 1540; d. Leiden, Dec. 31, 1610. While professor of fortification at Leiden he calculated the value of π to 35 decimal places; this computation is sometimes known as Ludolph's number.

CEUTA, thā'ōō-tā, Morocco, a strongly fortified place belonging to Spain, on the African coast opposite Gibraltar. The town occupies the site of the Roman colony of Ad Septem Frates, so called from the seven hills rising here in a group, of which the most prominent are Almiña and Hacho. On the latter, the ancient Abila (one of the Pillars of Hercules), is a fort; on the former, among beautiful gardens, lies the new town. Ceuta contains a cathedral, a hospital, and convents, but is chiefly of importance as a military and penal station. It was a flourishing mart under the Arabs, and there the first paper factory in the Western World is said to have been established by an Arab who had brought the industry from China. In 1415 it was captured and annexed by Portugal; it fell to Spain in 1580. It resisted several sieges by the Moors (1694-1720 and 1732). Ceuta is part of the province of Cádiz. Pop. (1948) 63,062.

CEVENNES, sā-vën' (ancient CEBENNA), the chief mountain range in southern France between the Alps and the mountains of Auvergne; it lies mainly west of the Rhône. With its continuations and offshoots, it forms the watershed between the river systems of the Rhône and the Loire and Garonne. Its general direction is from northeast to southwest, beginning at the southern extremity of the Lyonnais Mountains, and extending under different local names as far as the Canal du Midi, which divides it from the northern slopes of the Pyrénées. It is divided into the South and North Cévennes. The Cévennes extend for over 150 miles, through or into nine departments, the central mass lying in Lozère and Ardèche, where Pic de Finiels attains 5,584 feet, and Mont Mézenc (the culminating point of the chain) 5,754 feet. The average height is 3,000 to 4,000 feet.

CEYLON, sê-lôn', a large island of the Indian Ocean, lies off the southeast coast of India between latitudes 5°55'N. and 9°50'N. and longitudes 79°42'E. and 81°53'E. It is separated from the mainland by Palk Strait in the north and the Gulf of Mannar in the west. Between the strait and the gulf is a ridge of sandbanks, known as Adam's Bridge, which nearly joins the island to the mainland and interferes with navigation except for small boats. In 1796 the British captured Dutch settlements on the island. They administered the area from Madras until 1798, when it was made a crown colony. In 1802, under the Treaty of Amiens, Ceylon was formally ceded to Great Britain. Since Feb. 4, 1948, Ceylon has been a dominion of the Commonwealth

of Nations. The flag is that of the Sinhalese kings, with a standing yellow lion against a red background, to which have been added a green stripe symbolizing the Moslem population and a saffron stripe for the Tamils.

Roughly pear shaped, with the broad end to the south, the island extends 270 miles from Point Pedro (Point Palmyra) in the north to Dondra Head in the south. Ceylon's greatest breadth, from Colombo to Sangamankanda, is approximately 140 miles. The total area is 25,332 miles, or a little over half the size of New York State. The principal cities are Colombo (1946 population, 353,374), the capital, largest city, and principal seaport; and Jaffna (estimated 1946 population, 63,000), Dehiwala-Mount Lavinia (56,900), Kandy (51,200), Moratuwa (50,700), and Galle (49,000). Kandy, a former capital, is noted for its Buddhist temples, including Daladā Mālagāwa, the most sacred of all Buddhist temples.

The Land.—*Topography.*—Structurally, Ceylon is an extension of the south Indian plateau. The major portion of the island is composed of very ancient Archean gneisses overlain in many sections with thick metamorphosed sediments, such as quartzite, granulite, and crystalline limestone, which together make up the Khondalite system. The Khondalite series is folded into a complex syncline with a general north-northwest, south-southeast axial trend. The only other important rock type is a sedimentary Miocene limestone which fringes the northwest coast and covers the Jaffna Peninsula. The island is divided into three fairly distinct levels or zones. The highest level or terrace appears at 6,000 feet; the intermediate level, at around 1,600 feet; the lowest terrace, at 100 feet. Rising above the highest terrace, where local relief is considerable, are the highest peaks of Ceylon, the sacred Adam's Peak (7,365 feet), said by Moslems to contain the footprint of Adam, and Pidurutalagala (8,292 feet), the highest point on the island. The drop from the highest terrace to the 1,600-foot level is quite abrupt. Here there is considerable local relief with ridges and isolated hills rising from the terrace floor. The lowest terrace covers the northern two thirds of the island and is generally overlain with alluvial material. The average elevation of this plain is about 100 feet, though isolated hills rise to 200 or 300 feet above sea level.

The rivers form a radial pattern from the central highland core. Streams are generally short and swift; the longest, Mahaweli Ganga, a little over 200 miles in length, empties into Trincomalee Bay. Waterfalls, one of the major scenic attractions, are characteristic where the rivers drop from one terrace level to the next. The typical coastline is low with offshore coral reefs and sandbanks topped with dunes behind which lie both fresh- and brackish-water shallow lagoons. Coral flourishes all around the island, and most of the sand deposited on the beaches and dunes is composed of comminuted coral. Occasionally rocky headlands reach the water's edge, as at Galle on the southwest tip of the island. Although there are frequent inlets, the harbor facilities at Colombo itself are largely artificial, breakwaters having been constructed to afford protection from the open sea on both the north and west sides. Trincomalee, however, on the northeast coast, is reputed to be one of the finest natural harbors in the world.

Climate.—Ceylon's location and its local relief

features are the two chief determinants of its climate. Proximity to the equator gives the island a generally uniform tropical climate, but local elevation modifies the intensity of the heat. The lowlands are uniformly and continuously hot at all seasons, with average temperatures around 80°F. Seasonal variations generally amount to only 3° or 4°F., but they are slightly greater in the extreme north. Diurnal ranges are much greater than seasonal ranges. On clear days at Colombo it is not uncommon for day and night temperatures to differ by 15°F. In the highlands temperatures decrease in almost exact ratio to elevation. At Nuwara Eliya, above 6,000 feet, the average January temperature is 54°F., while in May, the hottest month, the average is 62°F. These differences between highlands and lowlands determine the kinds of crops which are raised at various elevations. While these average temperatures do not seem excessive, they are accompanied at all times by a high humidity which makes the heat feel more intense.

Rainfall on the island, as in India, is dominated by the monsoon winds. The seasonal change in wind direction causes a change in the location of the area of heaviest rainfall. In addition to rainfall resulting from the monsoons, local thunderstorms and tropical cyclones, especially during the intermonsoon periods, bring some rain to the island. The rainiest section is in the southwest. Here the rainfall everywhere is over 75 inches per year; on the windward slopes of the mountains it is in excess of 200 inches. The wettest period is in summer, during the southwest monsoon, but the balance of the year is by no means dry. The monsoon rains are generally heaviest in May. In the northern plains and in the extreme southeast, rainfall is everywhere less than 75 inches per year and many places receive less than 50. Moreover, rainfall here is much less reliable than in the southwest; it is primarily associated with the northeast (winter) monsoon winds; and there is a marked dry season with drought periods of up to 60 days in many sections, especially in the extreme north. Here irrigation is needed if agricultural production is to attain maximum yields. As a result of the marked contrast both in amount and in reliability of rainfall, this portion of Ceylon is agriculturally less productive than the southwest.

(W. F. C.)

Political Divisions and Population.—A census taken on March 19, 1946 gave the population of Ceylon as 6,695,605; of the total, 36,606 were nonresidents. The density was 262.8 persons per square mile. (In mid-1949 an official estimate placed the total population at 7,288,000.)

Table 1—PROVINCIAL AREAS AND POPULATIONS, 1946

Province	Area (in square miles)	Population	Percentage increase over 1931
Western	1,432	1,876,625	29.9
Central	2,290	1,134,584	19.0
Southern	2,146	962,006	24.7
Northern	3,429	479,639	20.2
Eastern	3,840	279,204	31.4
North-Central	4,000	139,581	43.4
North Western	3,016	668,192	22.2
Uva	3,277	373,059	23.0
Sabragamuwa	1,893	746,109	29.0
Total	25,332	6,658,999*	25.5

* Resident population.

The island is divided into 9 provinces, which are subdivided into 19 districts. A government agent is in charge of each province, and an assistant government agent of each district. Provincial areas and population-figures are given in Table 1; birth, death, and infant mortality rates, in Table 2.

(G. P. M.)

Table 2—BIRTH AND DEATH RATES; INFANT DEATHS (1941-48)

Year	Birth rate per 1,000 population	Death rate per 1,000 population	Infant deaths per 1,000 live births
1941	36.5	18.8	129
1942	36.7	18.6	120
1943	40.6	21.4	132
1944	37.1	21.3	135
1945	36.7	22.0	140
1946	38.4	20.3	141
1947	39.4	14.3	101
1948	40.5	15.2	92

The People.—The permanent population of Ceylon comprises Sinhalese (now, preferably, called Sinhalas); Tamils; Moors and Malays, together grouped as Moslems; Burghers, descendants, mixed and pure, of Portuguese and Dutch colonists of the 16th and 17th centuries; Eurasians; and Veddas (Veddahs), the remnant of an aboriginal stock. There is an Indian community of merchants and a larger group, mainly from south India, of estate laborers. There are also small communities of Europeans, Chinese, and Baluchis (commonly termed Afghans). In 1946 the number of immigrants was 282,925, of whom 95 per cent came from India; estate laborer Indian immigrants numbered 78,593. Emigrants numbered 226,135, of whom 97 per cent went to India; estate laborer emigrants numbered 75,939. The division of the permanent population by ethnic groups and religions is given in Table 3.

Table 3—ETHNIC GROUPS AND RELIGIONS, 1946 (in thousands)

Ethnic groups		Religions	
Sinhalese	4,637	Buddhists	4,288
Ceylon Tamils	826	Hindus	1,326
Moslems	393	Christians	606
Burghers, Eurasians, Euro-Ceylonee ..	36	Moslems	433
Indians	751	Others	5
Europeans	5		
Others	11		

The Sinhalese are the descendants of a north Indian people who are believed to have colonized the island in the 6th or 5th century B.C. They are generally divided into two groups, Low Country and Kandyan. The former inhabit the western and southern coastal areas, the latter the north central plain and the mountains. The division is not ethnic, but originated in the administrative cleavage caused by European occupation of the littoral. The Sinhalese are a handsome people, slender and well proportioned, with fine features and smooth black hair. The women, particularly, have a fine carriage and possess large, lustrous eyes. Skin color varies from light olive to dark brown. The Sinhalese are highly civilized, with a culture over 2,000 years old and four centuries' contact with Western thought. They are gentle and hospitable. The Ceylon Tamils, who live mainly in the arid north and the east, are an alert, industrious people who

came to political notice about the 14th century. Conservative descendants of south Indian colonists and invaders, they have largely retained their Indian way of life, unlike the Sinhalese, who early developed a civilization distinct from that of the subcontinent. The Moors engage chiefly in small-scale trade; the Malays, in services like the police and the fire brigade. The Veddas occupy the almost inaccessible forest regions of Uva and Eastern provinces. Once completely wild, they now cultivate dry crops, though they prefer hunting, for which they use a primitive firelock instead of the ancestral bow and arrow. They are a very dark people with pronounced Negroid features, speak a patois, and practice animism. They do not easily make friends with strangers. The Veddas are kin to the wild tribes dotting the forest patches of the arc extending from Borneo westward to India through the south Asian land mass. The Burghers have the lightest complexions of the permanent inhabitants. By endogamy a minority of the Dutch Burghers have preserved the European blood upon which they pride themselves, and they are striving to retain their individuality. The rest of the Burghers are merging into the other racial groups, notably the Sinhalese. Not long ago the Burghers filled the learned professions, such as law, medicine, and the church, or were prominent in European merchant firms. Their interests are becoming more diversified. The small Chinese community consists mainly of peddlers. The Baluchis are exclusively money lenders. (G. P. M.)

Natural Resources.—*Natural Vegetation.*—Forests cover some three fourths of Ceylon. Because of marked contrasts in rainfall and elevation the types of plants vary widely from place to place. The lower slopes of the mountains and the wetter portions of the lowlands, where the land has not been cleared, are covered with a thick, broadleaf evergreen forest composed of many species. Parasitic vines and creepers are common in the plant associations of these areas. On some of the higher plains where rainfall is scant, coarse grass is typical. In the highlands, where wetter conditions exist, temperate zone species prevail, and climbing plants are much less common. In those parts of the plains where a marked dry season is characteristic, thorn forest is typical. Elsewhere on the plains a dry zone forest with a great variety of trees, generally with small leaves and thick bark, is most frequent. It is from this type of forest that the slow-growing ebony and satinwood are obtained.

Animal Life.—Most of the animals found in India, except the royal tiger, are also native to Ceylon. Leopards and various types of small cats are common. In the northern and eastern provinces elephants are numerous, although their numbers have been greatly reduced by hunting. Bears, monkeys, wild hogs, and several species of deer are all found on the island. The bandicoot is a familiar garden pest, as it is in India. Great numbers of birds, many with bright plumage, are common. Especially numerous are pheasants, peacocks, partridges, and pigeons.

Mineral Resources.—Mineral wealth is neither extensive nor varied. The chief mineral industry, graphite (plumbago) mining, is subject to wide fluctuation both in the amount produced and in numbers employed. In 1940 about 18,000 were engaged in graphite mining; in 1946, only 1,785. Production dropped from a high of 27,734 tons

in 1942 to a low of 4,623 tons in 1946, but rose again to 14,194 tons in 1948. Commercial deposits occur in veins, lenses, and pockets in the Khondalite series. The principal markets are the United States and the United Kingdom. Good-quality mica occurs in the hill country, but mining has been haphazard, and production erratic. Precious and semiprecious stones, including sapphires, rubies, beryl, topaz, garnet, zircon, and many varieties of quartz, are obtained from the alluvial gravels derived from the Khondalite rocks. Since all gems are bought through auctions or private sales, no annual production figures are available; conservative estimates place the value at around \$500,000 per year. Iron ore sufficient to meet local needs is available, but coal is lacking, and cheap electric power is not yet a possible substitute. Although the island has considerable amounts of potential hydroelectric energy, relatively little had been developed by 1949. Colombo, with one exception, was the only city which provided electrical energy for other than domestic use and street lighting. Here an ever-increasing volume was used for industry. In Galle power was provided for a plywood factory at Gintota. In 1948 the island's electric power capacity was 21,000 kilowatts. Plans were under way in 1949 to develop hydroelectric energy; when completed, the projects were expected to give the island a total in excess of 100,000 kilowatts. (W. F. C.)

Agriculture.—Agriculture occupies a paramount position in the economic life of Ceylon. Fully 60 per cent of all gainfully employed persons are engaged directly in farming, and agricultural products account for well over 90 per cent of all exports. Despite this great emphasis on crop production, there is an inadequate supply of food for local needs. Food imports normally constitute one third or more of all imports; in 1948 they amounted to 52 per cent. Food supplies could be augmented considerably through the expansion of irrigation facilities in the dry portions of the north and in the southeast; in 1949 a three-year project to irrigate 120,000 acres in the Gal Oya Basin was begun.

Agricultural production falls into three major types: (1) the rice-coconut complex, (2) rice-vegetable-tobacco farming, and (3) plantation agriculture. The first two types are characterized by small-scale operations, intensive hand cultivation, and small capital investment. Plantation agriculture is generally carried on in large units, capital requirements are great, and financial success is geared to world market conditions. In terms of numbers employed, by far the most important is the rice-coconut type, localized in the southern three fourths of the island. It is the Sinhalese who practice this system. Rice is grown primarily as a subsistence crop; the coconut supplies some food, household articles, and a major cash crop. Some coconuts are grown under plantation methods, but the bulk of the island's production is derived from small-scale native plots. The rice-vegetable-tobacco form of agriculture is localized in the relatively unproductive soils of the Jaffna Peninsula and adjacent areas of the extreme north. This area is occupied predominantly by Tamils. Rice and vegetables are the chief food crops. Tobacco is grown on a commercial basis. Rainfall here is light (25 to 50 inches) and comes in the northeast monsoon period. Consequently irrigation is essential. The relatively infertile soil requires heavy

fertilization. Plantation agriculture is confined primarily to the hilly regions of the south. Tea (140,000 metric tons in 1948) and rubber (90,800 metric tons in 1949) are the dominant crops. Tea is grown from sea level to 6,000 feet, but the best qualities are obtained from the higher elevations; rubber is confined to elevations under 2,000 feet. (During the Portuguese and Dutch periods cinnamon was the chief plantation crop; in the 19th century coffee led all others, but in the 1870's a blight attacked the coffee tree, and cinchona was dominant for a brief period. It is only since the early 20th century that tea and rubber achieved first place.) Although rubber occupies a greater acreage than tea (573,243 in 1946 as compared with 533,830 in tea), its export value is far less: 14 per cent of the value of all exports in 1948, compared with 59 per cent for tea. World War II stimulated rubber production; its future seems less secure than that of tea.

An interesting agricultural system of Ceylon is chena cultivation. Under this system, practiced primarily in the dry zone, crops are grown on burned-off jungle land. As soil fertility decreases, the cultivator migrates to new areas. Fortunately this type is declining as lands are permanently cleared with government cooperation.

Acreage in principal crops, other than tea and rubber, in 1946 was as follows: rice (912,500), coconuts (920,093), vegetables and related crops (140,000), areca nuts (69,000), palmyra (50,000), cinnamon (33,077), citronella (30,107), cacao (19,700), cardamoms (6,000), and tobacco (2,656).*

Animal husbandry has occupied an unimportant place in the economy of Ceylon. After World War II four large cattle farms were started and attention was being given to the development of animals suited to the climate and to the production and processing of disease-free milk products. In 1946 there were 1,577,327 horned cattle, 296,151 goats, and 63,301 swine.

(W. F. C.)

Industrial Development.—Manufacturing is relatively unimportant in Ceylon, although shortages during World War II and attendant high prices and limited shipping space did much to stimulate industrial expansion along certain lines. Much of the war and postwar development was aided by government ownership and control. In 1939 the government built a coir factory to make such articles as camouflage material and bags for coal, tea, and salt. In 1946 some 5,000 workers were employed in the government-controlled machine phase of this industry. In addition, probably 50,000 were employed in cottage-type, small-scale coir spinning and weaving, some entirely under private control, some aided by the government. In 1941, a government plywood factory was built to supply tea chests, decorative panels, and furniture, and a shoe factory and a tannery were begun. In December 1942 a steel rolling plant using scrap metal was completed. Other government plants of wartime origin include a paper mill, a quinine factory, and a ceramics factory producing crockery and utility ware. The war also stimulated private development of such industries as those producing glass, matches, soap, hosiery, paper, twine, lacquered ware, and ink. The government assisted in the expansion of

many cottage-type industries, especially in such fields as textiles, pottery, rattan goods, mats, and handmade paper.

In the early postwar period the trend of industrialization was difficult to predict in detail, but certain features seemed fairly clear. First, there seemed little doubt that Ceylon would remain essentially an agricultural nation producing commercial crops. Second, the government would probably find it necessary to continue to play a major role in financing and controlling industrial expansion in such fields as power, heavy industry, fertilizer manufacture, cotton spinning, and certain pharmaceuticals. Third, for a considerable time private enterprise would probably be limited to consumers' goods for which processes are relatively simple, capital requirements small, and technical requirements at a minimum. Fourth, the cottage-type industry would continue to provide a source of income and supply many local necessities. (W. F. C.)

Trade.—The foreign trade of Ceylon consists primarily in the exchange of agricultural products for manufactured goods and food. While World War II had little effect upon the general character of the island's trade, it did modify it in detail and alter the direction of its movement, especially in imports. War-stimulated industries made the island less dependent on foreign sources for certain manufactured products than was true before the war. Disturbances during the war and in the postwar period cut off trade with Japan and interfered with the movement of rice from South-east Asia. The total value of both import and export trade increased manifold—imports, for example, from 236 million rupees to 985 million rupees between 1938 and 1948; exports, from 284 million rupees to 1,009 million rupees in the same period—but because of the very high prices that Ceylon had to pay for her imports (in 1948 the import price index was 525, on a base of 100 for 1934–1938, while the export price index was 344), there was relatively little real gain resulting from the increased value. In 1948 the major groups of import items and the percentage for each group included: food, drink, and tobacco, 52 per cent; manufactured products, 36 per cent; raw materials, 11 per cent. During the war there was a marked decline in the import of rice and a marked increase in the import of wheat and wheat flour, mostly from Australia, and bread has become an important item in the diet of many people in Ceylon. A marked increase in the import of preserved milk and milk foods was also noted. Tea, rubber, and coconuts dominated the export field in 1948, as they had for many years, tea accounting for 59 per cent, rubber for 14 per cent, and coconut products for about 13.5 per cent of the total export trade. A large portion of Ceylon's trade is with Commonwealth countries: 45 per cent of imports, and 52 per cent of exports, in 1948. In that year the chief sources of Ceylon's imports were the United Kingdom (17.4 per cent), Burma (17.4 per cent), India (12.8 per cent), Australia (12.7 per cent), and the United States (7.6 per cent). Exports in 1948 went primarily to the United Kingdom (29.8 per cent), the United States (16.3 per cent), Australia (8.3 per cent), Egypt (6.3 per cent), and the Union of South Africa (4.3 per cent). (W. F. C.)

Transportation and Communications.—All railways in Ceylon are government owned. The system, which comprises 806 miles of broad-gauge (5½ feet) and 106 miles of narrow-gauge

* These figures do not in many cases include holdings of less than one acre, of which there are many. The tobacco figures are inadequate, since they represent only the crop for one season and not for the entire year.

(2½ feet), focuses on Colombo and serves the southwest coast and the southern highlands, with two lines extending to the north, and two to the east coast. Large sections of the south and southeast are without rail service. There are over 17,500 miles of road and cart tracks in the island; 6,364 miles can be classed as main through arteries, of which 5,457 miles are surfaced and generally suitable for all-weather use. A series of canals along the southwest coast provides a water route of about 120 miles between Kalutara and Puttalam. Air transport is available to India, Pakistan, the United Kingdom, and Singapore. Colombo, one of the world's great entrepôts, has extensive wharfage facilities.

The telegraph and telephone systems are operated by the Post Office Department. As of Sept. 30, 1947, there were 1,046 post offices. In 1948 there were 11,110 miles of telegraph lines and 70,445 miles of telephone wires. The government maintains a broadcasting service with programs in English, Sinhalese, and Tamil. A great many newspapers and periodicals are published in Ceylon in all the major languages. (W. F. C.)

Economic and Financial Factors.—The standard unit of currency is the rupee; in May 1950 it was valued at 20.8 cents in U.S. money. The primary units of weights and measures are identical with those in Great Britain. There are some 15 banks doing business in Ceylon, many of them branches of Indian and British concerns. In addition, the post office savings banks, the State Mortgage Bank, and the Agricultural and Industrial Credit Corporation carry on limited and specialized banking functions. In 1950 the new Central Bank of Ceylon began functioning. Revenue was estimated at 565 million rupees in 1948-1949; expenditures at 532 million. In 1948 national income was about 2,272 million rupees. Between 1937 and 1950 the cost of living index rose from a base of 100 to 319. (W. F. C.)

Government.—The island as a whole first came completely under foreign control in 1815, and until 1931 was administered as a crown colony of Great Britain. In that year, the Donoughmore Constitution gave the island a great measure of self-government and almost entire control of finance. It also established universal suffrage. It provided government by ministers, of whom seven took office as chairmen of the executive committees into which the legislative assembly, the State Council, was divided. The broad model was the London County Council. In 1945 the Soulbury Commission made further changes, and on Feb. 4, 1948, Ceylon became a fully self-governing dominion in the Commonwealth of Nations. The postwar changes in Southeast Asia, particularly those which established the Dominions of India and Pakistan and led to the republican Union of Burma, doubtless accelerated the pace of Ceylon's progress to free nationhood.

The king is represented by a governor general. Parliament, on the British model, consists of two houses, the House of Representatives, with 101 members, and the Senate, with 30 members. The governor general nominates 6 members to the former, and 15 to the latter, to which the House of Representatives elects the balance. The interests of unrepresented minorities are safeguarded by nominations. The prime minister presides over a Cabinet of 14 members, whom he chooses. The first parliamentary elections, held in September 1947, gave a plurality of 42 seats to the United National Party, which came into

power with its chairman as prime minister. The opposition consisted mainly of Left-wing elements: the Communist (Stalinist) Party, and the Bolshevik Sama Samaja and Lanka Sama Samaja parties (both Trotskyist). The Ceylon Tamils allied themselves with their Indian brethren in the Tamil Congress Party. The Ceylon Indian Congress formed its own group. All of these joined in opposition to the United National Party. There were 21 Independent members. Subsequently, the government was strengthened by the accession of a number of Independents, by differences among the Left-wing parties, and by a major split in the Tamil Congress ranks, the leader of that group accepting a Cabinet appointment. The government in 1949-1950 was therefore a coalition. Complete executive power is exercised by the Dominion, which also controls all legislation. Certain appeals are allowed to proceed to the British Privy Council. The Supreme Court is the highest tribunal; it is presided over by a chief justice and several puisne judges. Of similar status are the commissioners of assize. There are a court of criminal appeal and other appellate courts presided over by one, or a board of, puisne judges. District, magistrates', requests', and rural courts exercise restricted powers. Civil law is based on the Roman Dutch law introduced by the Dutch in the 17th century. Criminal law is on the British model. Moslem marriages and divorces are governed by Koranic laws administered by boards of Kathis. The Ceylon Tamils have their own property law, known as Thesa Walamai. The police force operates under an ordinance of 1865, amended by later ordinances. At its head is a senior civil servant.

The prime minister is also minister for defense and external affairs. The island is represented by an ambassador in the United States, by a minister plenipotentiary in Burma, and by high commissioners in the United Kingdom, Australia, and India. In unrepresented countries its interests are served through the British government. India is also represented by a trade commissioner; Pakistan, solely by a trade commissioner. A citizenship law safeguards the island's position vis-à-vis nationals of other countries but enables them to be domiciled under conditions meeting the island's requirements. The law has had doubtful reception in India and Pakistan, but the influx of their nationals necessitated some restriction. The law also clarified the island's attitude toward countries seeking to discriminate against its nationals. The Ceylon Naval Volunteer Reserve and the Ceylon Army are the chief instruments of defense. Officers are trained in England. Defense is coordinated with British strategy and machinery.

Public health and welfare services and social legislation are advanced. The network of hospitals in the chief towns has been extended to remote areas, where numerous rural hospitals, maternity homes, and prenatal clinics have been established. Curative and preventive treatment is available at specialized clinics. In areas distant from transportation lines there is a system of outdoor dispensaries. There are also milk feeding centers for infants. Social legislation is administered largely by the Ministries of Health and Local Government and of Labour and Social Services.

Government service is controlled by the Public Services Commission, which recruits candi-

dates for higher government posts. The commissioners hold competitive examinations for young graduates seeking to join the civil service. Senior civil servants are appointed government agents. Each ministry is administered by a permanent secretary, generally a senior civil servant. Rural administration is under divisional revenue officers, aided by village headmen. Local government service covers the most remote areas. Cities and large towns are administered by municipalities, and smaller units by urban and town councils, while villages have village committees. Members are popularly elected. A local government commission unifies the service. (G. P. M.)

Way of Life.—The people of Ceylon are peace loving, law abiding, and gentle. They are tolerant of and receptive to new ideas. As a result, early Christian missionaries were welcomed warmly, although Christianity has made little headway since its introduction in the 16th century. Most Sinhalese are Buddhists; Tamils are Hindu by religion. The Buddhist Sabbath is reckoned by the four lunar phases. On these days Buddhists visit temples, offer flowers in memory of the Buddha, and listen to a sermon by a monk. The monks are celibate, eat but one meal a day, and live withdrawn from ordinary affairs. Religious ceremonies have comparatively little ritual, worship being individual. The Hindus are more ritualistic. Their priests are Brahmans, members of an exclusive priestly caste. Buddhist monks have no caste restrictions to prevent them from adopting a spiritual life, and they can renounce their religious calling at will.

Residents of towns live in semi-European style, but rural folk lead more natural and simpler lives. British law imposed monogamy except in the case of the Moslems. The Moors segregate their womenfolk, but there is a movement toward freedom. Malay women are not segregated. Tamil women are conservative, but neither the Sinhalese nor members of the other ethnic groups have imposed restrictions upon women. Family life is patriarchal, younger members being respectful toward their elders. Children are affectionately regarded. Marriages are arranged by parents, and the dowry system prevails. Property is inherited equally by all children in a family. The average meal consists of a large dish of boiled rice with several vegetables separately made into curries. Although meat and fish are eaten, the diet is mainly vegetarian. Most village folk chew betel leaf mixed with slices of areca nut, a pinch of burnt lime, and sometimes spices such as cloves and cardamoms. Persons educated in English, as well as those employed in government and other modern services, wear European clothes, but the majority of the population wear a cloth falling to the ankles and held at the waist, topped by a loose calico shirt or coat. In the villages many people normally are bare above the waist. Rural folk carry a large kerchief, shawl, or towel over one shoulder. Women wear bright-colored saris draped over the left shoulder, with a blouse underneath. Jewelry for hair, ears, neck, wrists, and sometimes ankles is much favored. Cricket, Rugby football, soccer, tennis, horse racing, and hockey are all popular, and national games are enjoyed in the rural areas. (G. P. M.)

CULTURAL LIFE AND ACHIEVEMENT

The civilization of Ceylon is more than 2,000

years old. Noteworthy among its achievements are those in architecture, painting, and engineering.

Art, Music, and Literature.—There are several ruined cities in Ceylon—notably Anuradhapura, the rock fortress of Sigiriya, Polonnaruwa, and Yapahuva, capitals at various periods from the 6th century B.C. to the 13th century A.D. They were well planned, ramparted, and moated. They had regular streets and surprisingly modern sanitation. Brick mounds, called dagobas (Sinhalese *dāgabas*), containing relics, were built in massive proportions. The largest, the 4th century Jetavana Dāgaba, at Anuradhapura, is over 250 feet high and has a diameter of 327 feet. Each dagoba is built on a platform, in a round or oval shape, with three rings, and a square on the summit, which is surmounted by a conical spire, capped by a gilded finial. About them are littered sculptured steps, balustrades, and door jambs. Some specimens of the stone sculpture and carvings rank among the finest in the world. There are also baths, rivaling Roman and Pompeian types, and what would today be called swimming pools. In addition, there are the remains of royal palaces, pavilions, and other buildings. All are in the dry zone, where the ancient kingdom flourished. The last of the Sinhalese capitals was Kandy, in the heart of the central mountain range. Architecture reached a very high standard, but gradually, during the period of decadence which culminated in the loss of independence in 1815, developed on folk lines now represented by the term Kandyana.

Under the stimulus of Buddhism the fine arts flourished. The classical period of Sinhalese art was between the 4th and 6th centuries A.D., and there were great revivals under royal patronage in the 11th, 13th, and 18th centuries. The finest paintings are those of the 5th century, represented by the celebrated frescoes of Sigiriya, still amazingly fresh. The next best known are the 12th century murals from the Tivanka image house at Polonnaruwa. Oils were used in very early times. Folk art is practiced in the Kandyana area, and well-preserved examples exist from the 18th century on. The tradition of architecture, painting, sculpture, music, handicrafts, and dancing has been continued by folk artists, with patronage from the Buddhist temples. The painting is flat and restful, resembling ancient Egyptian work. The treatment is narrative, and the object is repeated panel by panel. There is no true perspective. In handicrafts there is a tradition of fineness, fluency, and grace; the commonest objects—even kitchen utensils—are treated artistically. The Sinhalese have reached a high level of achievement in working with ivory, gold, silver, copper, brass, and wood. Most of the designs are traditional. The art of mat weaving and lacquer and filigree work is widespread in the villages.

Music, played by drums and flutes, is heard at village festivals, and at the annual festival held in connection with the Buddha's sacred tooth at the Daladā Mālagāwa in Kandy in August. At this time the best music and dancing native to the island is presented. There are many folk songs, and folk tales, replete with wisdom and a quaint sense of humor, are still told at village gatherings. While the theater is not highly developed, rural dramas, called *nadagam*, are played occasionally, and a movement to revive the drama on modern lines has been started. West-

ern motion pictures are popular, and Indian films attract large audiences. Sinhalese films made in India have revealed considerable talent.

Sinhalese, an Indo-Aryan language with many Dravidian words, dates from the beginning of the island's civilization and continues to be a medium suitable for expressing modern thought. Its literature, mainly religious, includes prose and poetry, philosophy, theology, and grammar of a high order.

Science and Technology.—The ancient Sinhalese excelled in engineering and irrigation. Vast artificial lakes, called tanks, dot the old kingdom. Most of them are being restored, and old water channels made to serve modern needs. The tanks were often built in chains, serving a series of villages before they reached their objective, the capital. The 5th century Jaya Ganga, the principal channel of the Kalaveva, is the best example of these old waterways. It takes water to Anuradhapura, 54 miles away; in its first lap of 17 miles the gradient is 6 inches to the mile. It is being used with levels intact. Minneri Tank, which covers about 4,500 acres, was built in the 4th century by King Mahasen. Modern counterparts are the Gal Oya project (see section on *Agriculture*) and the Laxapana hydro-electric project. The island has made great progress in scientific research. There is a medical research institute which has given Ceylon a leading position in the control of malaria and filaria. There are also research institutes for rubber, tea, and coconuts. The Department of Archaeological Survey carries on programs of excavation and conservation. Many valuable monuments have been preserved, and numerous important stone inscriptions discovered and published.

Education.—Primary and secondary education is controlled by the minister of education, and administered by the Department of Education. Primary education up to 11 years of age is in the mother tongue. Attendance is compulsory for children from 6 to 14 years of age. The schools are either run by the government, or, if conducted by organized religious denominations, aided by government grants. They are supervised by government inspectors acting under provincial education officers. Free education is the accepted policy, although a few older schools have been permitted temporarily to continue to charge fees. In 1948 there were 3,091 government schools, 3,146 assisted schools, and 623 English, central, and bilingual schools. The University of Ceylon, established on July 1, 1942 by the amalgamation of two colleges, has faculties of Oriental studies, arts, science, medicine, law, agriculture, and veterinary science; doctorates are given in letters, law, and medicine. Tuition is free. Courses are given in English. There are also industrial schools, polytechnic academies, and schools for the deaf and blind. Ceylon Technical College prepares students to the level of engineering degrees of the University of London. Adult education has made progress under a special education officer. There are a few public libraries maintained by local government bodies. The Department of National Museums administers Colombo Museum and other museums in the provinces. The attainment of dominion status stimulated the revival of indigenous arts and crafts, with full participation by the government. The Ceylon Society of Arts maintains an art gallery in Colombo, and in 1949 it organized the first of a series of art festivals. There is also

an active body, called the '43 Group, of modernist artists.

(G. P. M.)

HISTORY

The story of Ceylon begins traditionally in 543 B.C. (by an alternative system of chronology, 483 B.C.), with its colonization by the legendary Prince Vijaya. The most influential event in Ceylon's history, and the one which scholars generally make the starting point, was the Buddhist mission sent by Emperor Aśoka (r. c. 274–237 B.C.) of India to King Tissa at Anuradhapura.

Anuradhapura.—The Anuradhapura period of Ceylonese history lasted until the end of the 10th century A.D. In the 4th century a chronicle compiled from monastic records and known as the *Dipavamsa* related the history of Ceylon to the end of King Mahasen's reign (304 A.D.). A century later the better-known *Mahāvamsa* was compiled. It was continued from time to time, relating the story in 100 chapters to 1815. These two books constitute the chief source of the history of the island; they are often verified by inscriptions. They are written in Buddhist scriptural Pali verse (see INDIA, SUBCONTINENT OF—*Languages*). The greatest achievements of the Sinhalese were accomplished during the Anuradhapura period. The kings, though despots, were benevolent, and their rule was democratic to a considerable degree. Villages enjoyed a good deal of autonomy. The economy was agrarian, and cultural connections were largely with north India. The greatest ruler was Dutugemunu (Dutthagamani, r. 2d or 1st century B.C.), who is considered the savior of the island and its religion from Elala, a south Indian conqueror. In the 2d century A.D., King Gajabahu invaded south India and brought back many prisoners. Two centuries later there was a period of great vitality under the dynamic King Mahasen, builder of tanks, monasteries, dagobas, and other monumental structures. Under Kassapa (Kasyapa), of the 5th century, art flourished in its classic period. The island was known to Greeks, Romans, Egyptians, Arabs, and Chinese.

Polonnaruva.—At the close of the 10th century the Chola dynasty of southern India conquered the island, destroyed Anuradhapura, and made Polonnaruva its capital. When the Cholas were expelled by Vijayabahu I, in the mid-11th century, he continued their policy, and the city remained the capital for two centuries. The Polonnaruva kings, through political considerations, had more dealings with south India, and to this fact can be traced the distinct Dravidian-Hindu influences on the island's culture. Parakramabahu I the Great (r. 1153–1186), is the chief figure of this period. He unified the island, centralized its administration, and knit it together strongly as few of his predecessors had done. He showed great capacity for building and for making the island self-sufficient in food. He sent successful military expeditions to south India and Burma. Another energetic king was Nissanka Malla (r. 1187–1196). During the Polonnaruva period Ceylon was in touch with lands as far distant as Cambodia and China. Many Chinese coins and specimens of Sung pottery have been found in various places.

13th to 15th Centuries.—The fall of Polonnaruva in the 13th century was followed by a period of instability during which there were sporadic invasions from India, Malaya, and even China; capitals were moved from time to time;

and there was a marked trend toward the west coast. Parakramabahu II is the only powerful king of this period. His successors could barely keep the northern part of the island from breaking away into a separate kingdom under descendants of Tamil invaders, and they in fact ultimately established a kingdom of their own. Their power was checked in the 15th century by Parakramabahu VI. His capital was Kotte (near Colombo), the last capital of the traditional kingdom.

Portuguese and Dutch Rule; the Kingdom of Kandy.—In 1505 the Portuguese visited Ceylon, and in a few years, profiting by the weakness of the Kotte kings and the internecine warfare, were able to establish a hold on the maritime provinces which, confirmed by the Donation of Dharmapala in 1580, continued for 140 years. During this period the island had its first contact with European ways, with lasting effects. Roman Catholicism was introduced, and gunpowder was made known to the people, who also learned something of Portuguese language, dress, and music. Christianity was the chief contribution of the Portuguese. In 1638-1658, the Dutch drove the Portuguese from Ceylon. The Dutch United East India Company, with trade as its object, then took the place of Portuguese imperial rule in the maritime provinces. Meanwhile, the nationalist Sinhalese, resenting foreign influence in Kotte, left its King Dharmapala and the Portuguese to one side and established for a brief period the Kingdom of Sitawaka in the mid-country; it flourished under kings Mayadunne (r. 1521-1581) and Rajasingha I (r. 1581-1593). Upon the fall of Sitawaka in 1593, Sinhalese aspirations led to the formation of the independent highland Kingdom of Kandy, which in time came to control a large part of the island. (The Tamil kingdom in the north had already been destroyed by the Portuguese.) On several occasions Portuguese attacking Kandy were severely repulsed. Relations with the Dutch were better; they invaded chiefly to preserve their trade. In 1766, by the Treaty of Hanguranketa, King Kirti Sri (r. 1747-1782) of the Malabar dynasty (founded at Kandy in 1739) was forced to cede the entire seaboard to a depth of 4 miles to the Dutch. It was under this king that a great national and cultural revival took place. Meanwhile, the Dutch continued in control of the coast until 1796, when they were ousted by the British. The greatest contribution of the Dutch to the island was Roman Dutch law.

British Rule; the Dominion of Ceylon.—The British in their turn clashed with the Kandyan king, Sri Wickrema (Vikrama, r. 1798-1815), and his own people rose against him. In 1815 he was forced to abdicate and was deported to India, and the island went under British rule by the terms of a convention between the Sinhalese chieftains and the British governor. Three years later a serious rebellion almost drove the British out; there were other rebellions, in 1843 and 1848, but these were minor. The British introduced a colonial system of administration, and as the island became unified were able to bring about many useful changes. The country was opened up; coffee, tea, and rubber were introduced; coconuts were planted more extensively; and remote places were connected by road and rail. The opening of schools led to the gradual acceptance of English as the language of administration. The island was now brought into

line with European developments. Its special place in British strategy, as well as its importance to trade, was quickly realized. The people began to demand political advancement. Political reforms were introduced, culminating, on Feb. 4, 1948, in the end of British rule and the acquisition of dominion status. British occupation had resulted in steady progress. The lasting contribution of the British to the life of the island was parliamentary government. (G. P. M.)

CEZANNE, Paul, sã-zàn', French painter: b. Aix-en-Provence, Jan. 19, 1839; d. there, Oct. 22, 1906. The son of a banker, he did not have to contend with poverty despite the failure of his pictures to find purchasers for the greater part of his lifetime. He was a schoolmate of Émile Zola, who induced him to come to Paris in 1861. For a number of years Cézanne divided his time between Aix and Paris, where he came into contact with the best painters of his generation. Zola introduced him to Édouard Manet, and the young painter was soon acquainted with the group later called Impressionists, Pierre Renoir and Camille Pissarro being his particular friends. He exhibited with these artists in 1874, and again in 1877, when he submitted 17 paintings. Discouraged by the ridicule of the critics and by his differences with the Impressionists, Cézanne retired in 1879 to Aix, where he spent the remainder of his life. There he developed a style of great originality, which was to exercise a profound influence on the development of modern art. After a careful study of the old masters and an acceptance of the art of Eugène Delacroix and Gustave Courbet, he had next made himself master of the principles of their successors. This he did particularly during the two years (1873-1874) that he lived with Pissarro at Auvers-sur-Oise. But while the Impressionist ideas of light were his study during this period, he did not lose sight of the masters of the Louvre, and he made many experiments in applying latter-day knowledge to classic principles of design. In the early 1880's he was ready to begin a painting where personal inclination took on greater prominence as compared with inherited values. *L'Estaque*, at the Luxembourg in Paris, shows Cézanne on the road to his new style; the landscape (1888) at the Metropolitan Museum of Art in New York shows him firmly in possession of it. In his later years he went untiringly ahead, making clear to the next generation of painters that a profound conception of nature can be made by setting down a few essentials. His treatment of form and color rose to always greater heights. While most of his

works are still in private collections, he is represented, besides the museums noted above, in the Louvre, the Museum of Modern Art (New York), the Philadelphia Art Museum, and many other galleries. Cézanne's struggles and career are depicted in Émile Zola's novel *L'Oeuvre*.

A bold inaugurator, Cézanne was at the same time well aware of the great traditions of Western art and once summed up his goal succinctly as "de refaire Poussin d'après la nature" ("redoing Poussin after nature"). The fame and influence of Cézanne have grown enormously since his death. Though the humble master would have been the last one to countenance the idolatry later paid his work, the searching and experimental temper of his art helped undoubtedly to form the movements of post-Impressionism and Cubism, and it remains one of the strongest forces in modern painting.

CHABANEAU, shā-bā-nō', **Camille Jean Eugène**, French philologist: b. Nontron, Dordogne, France, March 4, 1831; d. there, July 22, 1908. A professor of Romance languages at Montpellier from 1879 until his death, he was a leading authority on Provençal philology and edited many old texts of the Languedoc. Besides contributing to the *Revue des langues romanes*, he wrote *Histoire et théorie de la conjugaison française* (1868); *Grammaire limousine* (1876); and *La langue et la littérature du Limousin* (1892).

CHABANEL, shā-bā-nēl', **Noël**, Jesuit missionary among the Huron Indians: b. near Menae, Lozère, France, Feb. 2, 1613; d. near St. Matthias Mission, Canada, Dec. 8, 1649. After entering the Jesuit seminary at Toulouse and teaching rhetoric in several colleges of the order, he was sent to New France (Canada) in 1643, where he studied the Algonquian language and labored as a missionary among the Indians until his death. The companion of his work was Father Charles Garnier; the story of their death at the hands of the Indians is recorded in the *Jesuit Relations* of 1649-1650. Chabanel and Garnier are among the group known as Jesuit Martyrs of North America, canonized by Pope Pius XI in June 1930.

Consult Wynne, J. J., *Martyrs of North America* (New York 1925).

CHABANNES, shā-bān', name of a noble French family from Limousin, particularly noted in the 15th century. Two of its best-known members were:

JACQUES DE CHABANNES (c.1400-1453), a French general during the reign of Charles VII, who served in the Hundred Years' War under Joan of Arc and participated in the Praguerie revolt (1440). Pardoned by the king he took a leading part in ousting the English from French territories.

ANTOINE DE CHABANNES, COMTE DE DAM-MARTIN. (c.1411-1488), Jacques's brother, also

combated the English and took part in the Praguerie. He presided over the tribunal that tried Jacques Coeur and later became a trusted servant of Louis XI.

CHABAS, shā-bās', **François Joseph**, French Egyptologist: b. Briançon, France, Jan. 2, 1817; d. Versailles, May 17, 1882. At first engaged in commerce, he began to devote himself to the study of hieroglyphics in 1851. His investigations centered chiefly on two periods of Egyptian history—the conquest of the country by the Hyksos, and the time of their expulsion. His principal work was *Mélanges égyptologiques*, 4 vols. (1862-1873). From 1873 to 1877 he edited *L'Égyptologie*, a journal.

CHABAZITE or **CHABASITE**, kāb'a-zīt, one of the zeolite (q.v.) minerals, generally definable as a hydrous silicate of aluminum, calcium, and sodium, with small amounts of potassium and occasionally of barium and strontium. It has a hardness from 4 to 5 and a specific gravity of 2.08-2.16. Though transparent, it varies in color from white to pale red or yellow and occurs in rhombohedral crystals as well as in amorphous forms. In North America it is found mainly in Nova Scotia, New Jersey, and Maryland.

CHABLAIS, shā-blē', historic Alpine region, France, now forming part of the Haute-Savoie Department. Lying south of Lake Geneva it encompasses the 5,000-foot limestone massif of the Savoy Alps. Cattle raising and cheese-making are the main industries. The chief town is Thonon-les-Bains. Chablais is a winter sports center, with the popular resort town of Évian-les-Bains. Together with Savoy, Chablais was ceded to France in 1860.

CHABLIS, shā-blē', Eng. shāb'lē, town, France, in the Department of Yonne, on the left bank of the Serein, 11 miles east of Auxerre. It stands in the midst of vineyards which produce the celebrated white Burgundy wine of the same name. In the town is the noted 12th century Gothic St.-Martin Church. Pop. (1946) 1,796.

CHABOT, shā-bō', **François**, French revolutionist: b. Saint-Geniez-d'Olt, Aveyron, France, 1759; d. Paris, April 5, 1794. In early life he entered the Capuchin Order, but later married the daughter of an Austrian banker and became a violent extremist. He was elected to the Legislative Assembly in 1791, and to the National Convention in 1792. On his motion, it is said, the Cathedral of Notre Dame was converted into the Temple of Reason. His rabid antimonarchist party was dubbed "Montagnards." Accused of bribery and fraud, he was arrested and guillotined at the same time as Danton.

CHABOT, Jean-Baptiste, French Orientalist and hagiographer: b. Vouvray, Indre-et-Loire, France, Feb. 16, 1860; d. Paris, Jan. 7, 1948. Educated at the seminary of Tours, at Louvain University, and at the Sorbonne, he was ordained to the priesthood in 1885, and for a time had charge of the department of missions in the Ministry of Public Instruction. In 1897 he was entrusted with an archaeological mission to Syria. Besides publishing numerous works on early ecclesiastical history and Orientalism, he

CEZANNE: Above: In "La meule" ("The Millstone") Cezanne transformed a pile of rocks and a forest into strong and lucid composition. Below: "Still Life With Apples." Cezanne painted apples particularly because their simple lines permitted him to concentrate on the problems which absorbed him most: form and color, space relations, and composition.

(Above) W. Idenstein & Co., Inc.; (below) Museum of Modern Art

bove: The self-contained composition of "Grande baigneuses" ("The Bathers") pointed a way to other painters.

eft: "Self Portrait," 1880—Cézanne once stated as his goal that he wished to achieve the "solidity and enduring quality of ancient art."

bove) Philadelphia Museum of Art; (left) Moscow Museum of Western Art; below) collection of Stephen C. Clark, New York

elow: "The Card Players" shows the artist's concern with developing the endless possibilities in form suggested by a subject—rather than the emotional significance of the subject's life.

was director of *Corpus scriptorum christianorum orientarium*, vols. 1-76 (1903-1914), and an associate editor of *Corpus scriptorum semiticorum*, issued by the Academy of Inscriptions and Belles-Lettres.

CHABOT, Philippe de (SEIGNEUR DE BRION; COMTE DE CHARNY; MARQUIS DE BUSANÇOIS), French soldier: b. about 1480; d. Paris, France, June 1, 1543. Having bravely defended Marseille in 1524, he was taken prisoner in 1525 by the forces of Emperor Charles V at the Battle of Pavia, where King Francis I was also captured. He was appointed admiral immediately after his release, and sent to Italy in 1529 to negotiate the ratification of the Treaty of Cambrai. As commander in chief in Savoy, in 1535, he effected the conquest of part of that country and of Piedmont. On his return to France charges of fraud were brought against him. He was found guilty and imprisoned (1541), but was soon afterward pardoned by Francis I, at the urgent solicitation of the duchesse d'Étampes, and reinstated in his position. Chabot is said to have been the first to suggest the project of colonizing Canada. His famous tombstone, probably sculptured by Jean Cousin, is now at the Louvre.

CHABRIAS, kā'brī-ās. Athenian general: d. Island of Chios, 357 B.C. He succeeded Iphicrates in the command of the Athenian forces before Corinth, in 392, defeated the Spartans at Aegina (388) and afterward assisted Evagoras I in Cyprus, and Acoris in Egypt, against the Persians. In 378 he led the army which the Athenians sent to the aid of Thebes against the Lacedaemonians (Spartans) under Agesilaus II, and saved his troops from impending defeat by a military stratagem renowned in antiquity, commanding them to await the attack of the enemy with pointed spear and shield resting on one knee. In 376 he won an important victory over the Lacedaemonian fleet off Naxos. Later he defended Corinth against Epaminondas. Chabrias took part in the expedition against Thrace at the outbreak of the so-called Social War, and fell in battle at the siege of Chios.

CHABRIER, shā-brē-ā', Alexis Emmanuel, French composer: b. Ambert, Puy-de-Dôme, France, Jan. 18, 1841; d. Paris, Sept. 13, 1894. He studied law at Paris and entered the government service, with music as an avocation, until 1880 when he began to devote himself entirely to his art. His work was strongly influenced by Richard Wagner. He composed the operas *Guendoline* (1886) and *Le roi malgré lui* (1887). Other works by him include *Dix pièces pittoresques* and *España*, an orchestral rhapsody, his first great success.

Consult Servieres, G., *Emmanuel Chabrier* (Paris 1912).

CHAC-MOOL, chāk-mōōl', the Maya rain god; also, according to tradition, a chief of the Maya Indians of Yucatán. In 1876 a statue was discovered in the ruins of Chichén-Itzá, Yucatán, which was thought to be a representation of Chac-Mool, and named accordingly. It is now in Instituto Nacional de Antropología e Historia, Mexico City, Mexico.

The term is also used to identify a certain type of reclining figure in ancient Mexican sculpture.

CHACABUCO, chā-kā-vōō'kō, town, Argentina, about 120 miles west of Buenos Aires. Founded in 1865, it is an important agricultural center. Pop. (1947) 12,917.

CHACABUCO, village and mountain pass, Chile, in Santiago Province, about 30 miles north of Santiago. It was the scene of a decisive victory (Feb. 12, 1817) of an Argentine-Chilean army under José de San Martín and Bernardo O'Higgins over the Spanish during the South American War of Independence. Pop. (1930) 684.

CHACHALACA, chā-chā-lā'kā, a fowl-like gamebird, *Ortalis vetula*, found from southern Texas to Central America. A slender bird, its body measures about twelve inches and the long tail another ten inches. The chachalaca is olive or greenish brown with large bare throat patches, which in the male becomes bright red in spring.

Chachalaca.

At morning and evening these birds assemble in the dense brush in which they live and cry very loudly, the syllables resembling *cha-cha-la-ca*. The trachea or windpipe, which has a long loop extending beneath the skin of the abdomen, doubtless adds to the volume of the sound which at times is almost deafening.

DEAN AMADON.

CHACHAPOYAS, chā-chā-pō'yās, city, Peru, capital of Amazonas Department, about 75 miles northeast of Cajamarca, situated on the eastern slopes of the Andes; altitude 7,638 feet. A bishopric, the ancient town on an Inca road goes back to an early pre-Columbian settlement. It was refounded in 1536 by the Spaniard Alonso de Alvarado. Gold, silver, and coal deposits are in the vicinity. Pop. (1940) 5,494.

CHACMA, chāk'mā, the Cape baboon's (*Papio porcarius*) Hottentot name. The males of this very large grayish-brown baboon of South Africa are about the size of an English mastiff. They roam around in large herds and cause considerable damage to cultivated crops. See also BABOON.

CHACO, chă'kō, Span. chă'kō, or EL CHACO or GRAN CHACO, region in South America, vast low-lying plain situated in the south-central part of the continent's interior and covering roughly 250,000 square miles. Divided between Paraguay, Argentina, and Bolivia, the long-disputed, though generally backward land is bounded in the east by the Paraguay and Paraná rivers (of the Río de la Plata system) and extends westward to the foothills of the Andes. (Sometimes adjoining parts of Brazil are also considered to belong to the Chaco.) In the north, at about 18° southern latitude, it merges with the tropical forests (selvas) of Bolivia, while its southern section, considered to terminate at the Río Salado of Argentina, is bordered by the Pampa.

Of a tropical to subtropical climate, the Chaco is sparsely populated and consists largely of semi-desert savannas and scrub forests. During the humid summer season large tracts are flooded, and the dry winter leaves them barren. Along the rivers lie good grazing grounds. So far of limited economic importance, the region's chief products are quebracho bark, from which tannin is extracted, timber (laurel, quebracho, carob, guaiacum, etc.), and cattle. Only the Argentinian section is now being energetically developed, and has become a valuable source of cotton. The Chaco's principal rivers, the Pilcomayo and Bermejo (Teuco), which traverse it in a southeasterly direction to join the Paraguay, divide it into the Chaco Boreal, the Chaco Central, and the Chaco Austral.

The CHACO BOREAL has been largely held by Paraguay since 1938, as a result of the Chaco War (q.v.). The Paraguayan section is divided into Presidente Hayes, Boquerón, and Olimpo departments. The western and northern fringes are in Bolivia—eastern parts of Tarija and Chuquisaca departments and southern Santa Cruz. It is believed that the sparsely settled Chaco Boreal will eventually support a much larger population.

The CHACO CENTRAL, ceded by Bolivia to Argentina in 1889, is situated between the Pilcomayo and Bermejo rivers, and consists of the national territory of Formosa and the northeastern section of Salta Province. It is adjoined by the CHACO AUSTRAL, a warm, predominantly humid area of northern Argentina comprising, besides the former Chaco Territory (Presidente Perón), parts of Salta, Santiago del Estero, and Santa Fé.

The former CHACO TERRITORY of the Argentine Republic, renamed PRESIDENTE PERÓN in 1951 when it was elevated to the status of a province, is bounded on the north, along the Bermejo, by the territory of Formosa, on the east, along the Paraguay and Paraná rivers, by Paraguay and the province of Corrientes, on the south by the province of Santa Fé, and on the west by the provinces of Salta and Santiago del Estero. Receiving in the 20th century a considerable influx of European immigrants, who were offered favorable terms by the national government, the province, once roamed by the native Indian population, has made great strides, producing cotton, its chief commercial crop, corn, citrus fruit, peanuts, tobacco, maté, jute, sugar cane, and sunflowers. Cattle raising, meat packing, lumbering (hardwoods), tannin extracting (from quebracho), and various processing industries based on the region's products are centered at Resistencia (1947 pop. 51,834), a rail and communication junction with river ports on the Paraná. The province

covers 99,633 square miles; pop. (1951 est.) 505,284.

CHACO CANYON NATIONAL MONUMENT, archaeological site, northwestern New Mexico, on the small Chaco River and in the Chaco Canyon, about 50 miles northeast of Gallup. Covering an area of 18,039 acres, it was established as a national monument in 1907. The extensive ruins, among which are 13 major pueblos of an advanced, probably 11th century A.D. civilization of Basket Maker and Pueblo Indians, are among the North American continent's leading pre-Columbian structures outside Mexico. The most imposing ruins are those of Pueblo Bonito, a village with five-story buildings backed by a sandstone cliff.

CHACO WAR, armed hostilities between Bolivia and Paraguay which raged from 1932 to 1935 over parts of the Chaco (q.v.) in the fork of the Paraguay and Pilcomayo rivers. A territory long disputed between the two nations, it was during the Spanish administration a part of the *audiencia* of Charcas, to which Bolivia had become the rightful heir. The latter, however, neglected the Chaco, while Paraguay opened it up to settlement and repelled the Indian tribes. It was only after the War of the Pacific (1879-1884), when Bolivia lost its access to the sea, that this nation turned its attention again toward the Chaco in order to seek an outlet on the navigable Paraguay River. With the discovery of rich petroleum wells in the western section, the region's great economic potential came to be fully realized by the two powers. A border incident broke out in 1929, but large-scale military operations did not start until 1932. Bolivia was successful at first, but both nations suffered a severe drain in manpower (sometimes estimated to have been as high as one million men killed and wounded), and Paraguay had gained the upper hand by 1935, when an armistice was concluded. The League of Nations, which had declared Paraguay the aggressor, tried to mediate, as did several Pan-American conferences but it was only in 1938 that the conflict was finally settled at Buenos Aires by the joint arbitration of Argentina, Brazil, Chile, Peru, Uruguay, and the United States. Paraguay was awarded approximately three quarters of the territory, while Bolivia kept the petroleum-bearing strip in the west and obtained permission to use Puerto Casado (to be linked with Bolivia by a corridor) on the Paraguay River as a free port.

CHACONNE, shă-kôn', Sp. CHACONA, an old and stately dance, in 3/4 time, probably of Spanish or Moorish origin. It was very popular in the 16th and 17th centuries. There are numerous examples of it in the instrumental and vocal works of Christoph Willibald Gluck, Johann Sebastian Bach, George Frederick Handel, Jean Philippe Rameau, and Henry Purcell. It is heard in Johannes Brahms' *Fourth Symphony*.

CHACORNAC, shă-kôr-năk', Jean, French astronomer: b. Lyon, France, June 21, 1828; d. Villeurbanne, near Lyon, Sept. 6, 1873. He worked at the Paris Observatory under Urbain Jean Joseph Leverrier, and discovered six asteroids while making ecliptic charts of the stars. His *Atlas éclipse* (1856) was continued by Paul Henry (1848-1905).

CHAD, chād (officially in French: TCHAD, chād), northernmost territory of French Equatorial Africa, extending northward as far as Libya and bounded on the east and west, respectively, by the Anglo-Egyptian Sudan and Niger, the latter a territory of French West Africa. Named for Lake Chad, on the southwest border, it has an area of approximately 495,750 square miles. Fort-Lamy, on the Chari (Shari) River in the southwest part of the territory, is the capital. Most of Chad consists of sandy desert, oases being few and far apart. At the northern end of the territory are the Tibesti Mountains, of which Emi Koussi (11,201 feet) is the highest point, and the Ennedi range, the highest peak of which has an elevation of 4,756 feet. The forested southern end is traversed by the Chari and its tributaries. French expeditions explored the area during the last decade of the 19th century, and in 1910, after native kingdoms had been subjugated, the Ubangi-Shari-Chad colony was established. Chad became a separate colony in 1920, and in 1946 it was constituted a territory within the French Union. Pop. (est. 1950) 2,238,200. See also FRANCE—Overseas Territories (Administration); and FRENCH EQUATORIAL AFRICA.

CHAD, Lake, northwest-central Africa, at the junction of the boundaries of French Equatorial Africa, French West Africa, and the northeastern end of Nigeria. The area is some 8,000 square miles during the rainy season, shrinking to less than half that size in dry weather. Although the lake is fed by the Chari (Shari) River and other streams, there is no visible outlet, and much water is lost by evaporation and percolation. Lake Chad was first seen by white men in 1823, when it was visited by Hugh Clapperton and Dixon Denham, British explorers.

CHADBOURN, chād'bērn, town, North Carolina, in Columbus County, about 50 miles west of Wilmington, N. C., and on the Atlantic Coast Line railway; it is a strawberry-shipping point. The town was incorporated in 1883. Pop. (1950) 2,103.

CHADDERTON, chād'ēr-t'n, urban district, Lancashire, northwest England, adjoining Oldham. An industrial town, it manufactures cotton goods, metalware, and pharmaceuticals. Pop. (1951) 31,114.

CHADDS FORD, chādz fōrd, village, Pennsylvania, in Delaware County, on the Brandywine Creek, where Washington was defeated (Sept. 11, 1777) by the British who then advanced to Philadelphia. See also BRANDYWINE, BATTLE OF THE.

CHADERTON, chād'ēr-t'n, Laurence, English Puritan divine: b. Lees Hall, Oldham, Lancashire, ?1536; d. Cambridge, England, Nov. 13, 1640. Converted to Protestantism while studying at Cambridge, he was later chosen master of the newly founded (1584) Emmanuel College, an office he held until 1622. A noted scholar of Latin, Greek, and Hebrew, as well as a popular lecturer at St. Clement's in Cambridge, Chaderton lived to an active old age in the full possession of his mental faculties. He is principally known for having served on the committee of Cambridge scholars who drew up the authorized version of the Bible (1607–1611).

CHADRON, shād'rūn, city, Nebraska, seat of Dawes County, about 50 miles north of Alliance and on the Chicago and North Western Railroad. It is situated in the Pine Ridge hills at 3,395 feet. There are railroad shops here; other economic activities include oil refining, flour milling, dairying, and trading in livestock. Chadron is the seat of the coeducational Nebraska State Teachers College, founded in 1911; nearby is Chadron State Park. The city manager plan of local government was adopted in 1950. Pop. (1950) 4,687.

CHADWICK, chād'wīk, Sir Edwin, English social reformer: b. Longsight, near Manchester, England, Jan. 24, 1800; d. East Sheen, Surrey, July 6, 1890. A lawyer by training, he early took an interest in municipal administration and sanitation problems. An article he wrote on police administration impressed Jeremy Bentham, and he became Bentham's collaborator. On Bentham's death in 1832, Chadwick was appointed to the Poor Law Commission. His report on child labor in factories led eventually to the adoption of the Ten Hours Act and the Employers' Liability Act. His investigation of public health conditions in London led to the establishment of the Board of Health in 1848, with Chadwick as a member. He was also responsible for the appointment of the first civil service commission in England, in 1855. He was knighted in 1889. His many writings were abridged and edited by Sir Benjamin Ward Richardson in two volumes, entitled *The Health of Nations* . . . (London 1889).

Consult Jones, D. D., *Edwin Chadwick and the Early Public Health Movement in England* (Iowa City 1931).

CHADWICK, French Ensor, United States naval officer and historian: b. Morgantown, Va. (now W. Va.), Feb. 29, 1844; d. New York, N. Y., Jan. 27, 1919. After graduating from the United States Naval Academy (then at Newport, R. I.) in 1864, he served aboard naval vessels, was an instructor at the United States Naval Academy, Annapolis, Md., and in 1882 was appointed naval attaché (the first American to hold such an office) in London. Later he was made chief of the Office of Naval Intelligence and the navy's Bureau of Equipment. During the Spanish-American War he became chief of staff to Admiral William Thomas Sampson and took an important part in the Battle of Santiago de Cuba (July 3, 1898). From 1900 until 1903 Chadwick was president of the Naval War College. Among his writings are *Causes of the Civil War, 1839–1861* (*American Nation Series*, vol. 19, 1906); *Relations of the United States and Spain, 1776–1898*, 3 vols. (1909–1911); and *The American Navy* (1914).

CHADWICK, George Whitefield, American conductor and composer: b. Lowell, Mass., Nov. 13, 1854; d. Boston, Mass., April 4, 1931. One of the most prolific American composers of his time, he had studied during 1877–1879 in Germany, and, following his return to the United States, was appointed organist of the South Congregational Church, Boston. In 1897 he resigned this post to become director of the New England Conservatory of Music, Boston, and he continued to head this institution until his retirement at the end of 1930. His many compositions for orchestra include three symphonies and the overtures: *Rip Van Winkle* (1879); *Thalia* (1883); *The Miller's Daughter* (1884); *Melpomene*

(1891); *Adonais* (1898); *Euterpe* (1906); and *Anniversary Overture* (1922). He was probably at his best in choral works such as *The Viking's Last Voyage* (1881); *Lovely Rosabelle* (1889); *Phoenix Expirans* (1892); and *Land of Our Hearts* (1918). His most ambitious works are a lyric drama, *Judith* (1900); the opera *The Padrone* (1915); and *Love's Sacrifice* (1917), a pastoral opera. Other works for the stage are the comic operas, *The Quiet Lodging* (1892) and *Tabasco* (1893). Chadwick also composed for piano and organ, and wrote a number of songs, besides several texts on musicology.

CHADWICK, Henry, American baseball pioneer and sports writer: b. Exeter, England, Oct. 5, 1824; d. April 20, 1908. He settled in the United States in 1837 and became a prominent sports writer for several Brooklyn and New York papers. Often called "the Father of American Baseball," he took a leading part in the evolution of the game. He drew up rules for it in the late 1840's, and from 1869 published an annual baseball handbook, later known as *Spalding's Official Base Ball Guide*. Chadwick's opinion that baseball originated in the old English game of rounders involved him in a dispute with his friend Albert Goodwill Spalding (q.v.), but he bequeathed his large collection of materials on baseball history to Spalding, who included it in the Spalding Baseball Collection now at the New York Public Library. Chadwick also wrote on football and cricket.

CHADWICK, Sir James, English physicist: b. Manchester, England, Oct. 20, 1891. After receiving his M.Sc. degree from Victoria University in Manchester, he worked in Ernest Rutherford's laboratory and in 1913 went on a scholarship to the Physikalisches-Technische Reichsanstalt in Charlottenburg, Germany, where he studied with the physicist Hans Geiger. At the outbreak of World War I he was interned at Ruhleben, Germany. At the end of the war, he joined Rutherford at the Cavendish Laboratory at Cambridge University, where he received his Ph.D. in 1921, and became a lecturer and assistant director of radioactive research. In 1932 he discovered the neutron by bombarding beryllium with alpha particles. (See ATOMIC THEORY—*The Atomic Nucleus*.) The same year he received the Hughes Medal of the Royal Society, of which he had been a fellow since 1927. In 1935 he was awarded the Nobel Prize in physics, and became Lyon Jones professor at the University of Liverpool.

During World War II he directed nuclear research on the British atomic project and worked at Los Alamos, N. Mex. Knighted in 1945 he was appointed scientific adviser and alternate delegate to Sir Alexander Cadogan—Britain's representative on the United Nations Security Council—and British representative on the Atomic Commission of the United Nations. In 1948 he became master of Gonville and Caius College, Cambridge. Among the many honors bestowed on him are the Copley Medal (1950) and the Franklin Medal of the Franklin Institute, Philadelphia (1951). Together with Lord Rutherford and Sir Charles Drummond Ellis, Chadwick wrote *Radiation from Radioactive Substances* (1930); a revised 4th edition appeared in 1953 under the title *Radioactivity and Radioactive Substances*.

CHAEREA, kêr'ê-â, Gaius Cassius (some-

times called *Cassius Chaerea*), Roman soldier and conspirator: executed Jan. 25, 41 A.D. While a tribune in the Praetorian Guard he was mocked by the emperor, Caligula, for his high-pitched voice and supposed effeminacy. This insult is considered the chief reason for his plot against Caligula. During the Palatine games, on Jan. 24, 41 A.D., the emperor was walking to the circus when he was stabbed by Chaerea and Sabinus another tribune. The guard then proclaimed Claudius emperor, but Chaerea and some of the other conspirators were sentenced to immediate execution.

CHAEREMON, kê-rê'môn, a 4th century B.C. Athenian tragic poet, whose *Centaurus* is mentioned in Aristotle's *Rhetoric*. A few fragments of his writings survive.

CHAEREMON, a 1st century A.D. Alexandrine Stoic philosopher and author, who in 49 A.D. went to Rome as tutor of the young Nero. He wrote historical works on Egypt, and various treatises on astrology, religious cults, hieroglyphics, and grammar, but virtually none of his work has been preserved.

CHAERONEA, kêr-ô-nê-â, an ancient Greek town (now CHAERONEIA) in western Boeotia, west of Lake Copais and southeast of Mount Parnassus, near Orchomenus. It stands at the head of the last defile where a stand could be made against an invader of central Greece; and is famous as the birthplace of Plutarch, the Greek biographer, and as the scene of two great battles.

In 338 B.C. Philip II of Macedon, assisted by his son Alexander, here defeated the united forces of the Athenians and Thebans (or Boeotians), and thus crushed the liberties of Greece. Excavations near the modern village have unearthed a well-preserved theater and pieces of a gigantic lion commemorating the spot where the Thebans fell. The lion was re-erected in 1905.

In 86 B.C. the Roman general Lucius Cornelius Sulla (q.v.) defeated the generals of Mithridates VI, king of Pontus, at Chaeronea. Sulla claimed to have lost only 15 men in the battle.

CHAETODONTIDAE. See BUTTERFLY FISHES.

CHAETOGNATHA, kê-tôg'nâ-thâ, a phylum and class of marine worms, also called arrow worms. See ANIMAL CLASSIFICATION; and NEMATHELMINTHES.

CHAETOPODA, kê-tôp'ô-dâ, a class of worms belonging to the phylum Annelida, characterized by segmentation and the almost invariable possession of bristles (*chaetae*), usually four bundles to a segment. They comprise the earthworms, the leeches, certain fresh-water and numerous marine annelids, such as the lugworm, *Serpula arenicola*, and many other genera. The most common and one of the largest American chaetopods is the clamworm (*Nereis virens*), which is associated with the clam of the New England coast, burrowing deeply in the mud. The marine forms undergo a metamorphosis, hatching as top-shaped, free-swimming larvae, called trocophores. Some of the forms, as *Nais*, *Syllis*, and *Autolytus*, also multiply by a process of self-division called strobilation, and by alternation of generations. Some of them, as *Serpula* and *Spiro-*

bis, live in solid calcareous tubes or shells. Certain forms are luminous. The tracks of chaetopod worms occur in Cambrian strata, and are so much like those made by existing forms that it is evident the type has undergone little change since the Cambrian period, which lies at the very base of the Paleozoic Age. Sometimes practically all the Annelida are known as Chaetopoda. See also ANNELIDA or ANNULATA.

CHAETOPTERUS, kē-tōp'tēr-ūs, a genus of sedentary, marine polychaete worms of the phylum Annelida which live in secreted U-shaped tubes that are open at both ends. Water is drawn through the tubes by modified parapodia, so-called fans.

CHAFARINAS, chā-fā-rē'nās, or **ZAFARIN ISLANDS**, zāf'ā-rin, (sometimes also spelled CHAFFARINAS), a group of three small Spanish islands, off the coast of Spanish Morocco in the Mediterranean Sea, 27 miles east-southeast of Melilla, from which they may be reached by boat.

Called Tres Insulae by the Romans and Zafran under Arab rule, the islands were the haunt of Barbary pirates until 1848 when they were annexed by Spain. Congreso, the largest island, rocky and hilly, has an observation tower. A great landlocked harbor, sheltering the largest ships, has been created by a breakwater uniting the central island, Isabel II, with Rey nearby. Isabel II is the only inhabited island, with about 300 inhabitants, including a garrison. The islands belong administratively to Málaga.

CHAFER, chāf'ēr, the name for several kinds of beetles, but particularly for members of the family Scarabaeidae. The name is apparently derived from the German *Käfer* (beetle). The widely distributed rose chafer, *Macrodactylus subspinosus*, attacks the flowers and foliage of roses, grapes, and other plants, while the larvae live on the roots.

CHAFFEE, chāf'ē, **Adna Romanza**, American soldier: b. Orwell, Ohio, April 14, 1842; d. Los Angeles, Calif., Nov. 1, 1914. He began his military career in the Civil War (1861) as a private, and was rapidly promoted for efficient service, being commissioned 2nd lieutenant in 1863 on direct order of Secretary of War Stanton. He was wounded twice, and captured in the Gettysburg campaign, but he refused parole and escaped. His commanding officer persuaded him to remain in the army at the close of the Civil War, and in the next 25 years he served in the Southwest, acting at times as Indian agent. In the Spanish-American War, in 1898, he was given a brigade and distinguished himself in the engagement at El Caney, whereupon he was promoted major general of volunteers. He served as chief of staff to the military governor of Cuba from December 1898 to May 1900. He was sent to China during the Boxer Rebellion to command the United States troops at Peking. In 1901 he became a major general in the regular army and took over the command of the Division of the Philippines. Advanced to lieutenant general and chief of staff of the army in 1904, he retired in 1906.

CHAFFEE, **Adna Romanza**, United States army officer: b. Junction City, Kans., Sept. 23,

1884; d. Boston, Mass., Aug. 22, 1941. Son of the preceding, he graduated from West Point in 1906 and finished his training in Cuba, where he became one of the outstanding horsemen in the army. He graduated from the Saumur cavalry school in France in 1912, and served in World War I in the Saint-Mihiel and Meuse-Argonne offensives, winning the Distinguished Service Medal. On the basis of his experience in the war he urged the War Department to equip the army with tanks and tractor-drawn trucks, and in 1934 organized the United States Army's first mechanized brigade. In August 1940 he was made a major general.

CHAFFEE, chāf'ē, city, Missouri, in Scott County, about 100 miles south-southwest of St. Louis; served by the Chicago and Eastern Illinois, and the St. Louis and San Francisco railroads. It is a center of trade in agricultural products, and of textile and leather goods manufacture. The city was incorporated in 1906. Pop. (1950) 3,134.

CHAFFINCH, chāf'inch, a familiar Old World songbird (*Fringilla coelebs*) of the finch family, very common in England and throughout Europe, but also occurring in some parts of Asia and in North Africa and the nearby Atlantic islands. It is about six inches long. The female is inconspicuously colored but the male is very handsome with a bluish head, reddish cheeks, pinkish breast, chestnut back, and black wings with striking white bars. In addition to its beauty, this very popular bird has a confiding nature and quickly becomes friendly to the point of tameness. It is a favorite cage bird in Europe, valued for its beauty, its gaiety, and its loud and cheerful song, which is susceptible of training. See also FINCH.

DEAN AMADON.

CHAFIN, chāf'in, **Eugene Wilder**, American prohibitionist and politician: b. East Troy, Wis., Nov. 1, 1852; d. Long Beach, Calif., Nov. 30, 1920. He studied law and practiced in Waukesha, Wis., from 1876 to 1900, when he moved to Chicago and served as superintendent of the Washington Home for Inebriates from 1901 to 1904. He became known as an eloquent speaker and an active organizer in the temperance and prohibition movements, and was the Prohibition Party candidate for several public offices, notably for governor of Wisconsin in 1898, and in 1908 and 1912 for the presidency of the United States. In 1909 he was admitted to the bar of the United States Supreme Court. His published writings include *Lives of the Presidents* (1896); *Lincoln; the Man of Sorrow* (1908); *Washington as a Statesman* (1909); and *The Master Method of the Great Reform* (1913).

CHAGALL, shū-gāl', **Marc**, Russian painter: b. Liozno, near Vitebsk, Belorussia, July 7, 1887. As a youth, he worked as a photo-retoucher in his native town until, when 20 years of age, he ran off to St. Petersburg (now Leningrad) to study painting seriously. Soon tired of the formalism taught in the academic art schools of the capital he enrolled with Léon N. Bakst, who was then connected with the Diaghilev Ballet. Though his highly imaginative scenic designs were rejected for their extravagant flights of fancy, Bakst agreed to take him to Paris with

the ballet company in 1910. Here Chagall immediately felt at home. Cubism, a strong new force in French art, acted upon him as a liberating influence, though he was not committed to this or any other school of painting, but to his own visionary temperament alone. He gave full vent to the whole range of his exuberant palette and the childlike, mystical, grotesque imagery evoked by his memories of Russian-Jewish village life. His canvases of floating people, humanized animals, and ecstatic physical objects—defying the law of gravity and the customary standards of realism—seemed to recreate the magic spirit of eastern folklore. It was Chagall's aim to remake or rather parallel nature, and when he held his first exhibition in 1914 at Berlin, his art was hailed by Guillaume Apollinaire as "supernatural" (or surrealist). For similar reasons Chagall has been called a forerunner of German expressionism and Italian futurism.

Following this first success, Chagall returned for a visit to Russia when World War I broke out, and had to stay there for the war's duration. After the October Revolution in 1917, he founded with Soviet support an art school and museum at Vitebsk, where he also acted for a while as minister of art. Besides several magnificent portraits of rabbis, he did murals for the Granowsky Jewish State Theater, and painted sets for the great productions of the early Soviet stage. But his modernistic art met with increasing disfavor from the new masters of Russia, whose tastes reverted to the representationalism of traditional Western painting. In 1923 he returned to Paris and took out French citizenship. It was then that he executed, upon the commission of Ambroise Vollard, his famous book illustrations for the *Fables of La Fontaine*, Gogol's *Dead Souls*, and the Bible.

The defeat of France in 1940 forced Chagall to take refuge in the United States, where he resided from 1941–1948. Here he resumed his creative activities by designing ballet sets and costumes for Léonide Massine's *Aleko* and Igor F. Stravinsky's *Fire Bird*. During this period he painted his *Descent from the Cross* (Museum of Modern Art, New York), and many other intense pictures which left an indelible imprint on modern American art. Among Chagall's best-known paintings in American museums are *The Rabbi of Vitebsk* (Art Institute, Chicago) and *I and My Village* as well as *Birthday* (Museum of Modern Art, New York).

The artist returned to Europe in 1948, and settled at Vence in the south of France. The same year he won the International Prize for Engraving at the Venice Biennale. The Salle Chagall at the Musée d'Art Moderne in Paris was inaugurated in 1950.

Consult Chagall's autobiographical *Ma Vie* (1931); Venturi, Lionello, *Marc Chagall* (New York 1945); Sweeney, J. J., *Marc Chagall* (New York 1946); and Kloomok, I., *Marc Chagall: His Life and Work* (New York 1951).

CHAGAS' DISEASE, shá'gás, an acute or chronic disorder, known also as South American or Brazilian trypanosomiasis (q.v.). It was first described in 1909 by Carlos Chagas (1879–1934), a Brazilian physician. It is caused by *Schizotrypanum* (or *Trypanosoma*) *cruzi* and transmitted to man by biting bugs. It is a fatal disease, marked by fever, myxedema, and enlarged lymph glands, spleen, and liver; and later by symptoms referable to the heart, endocrine glands, and nerv-

ous system. There is no known effective treatment.

HAROLD WELLINGTON JONES, M.D.

CHAGOS ISLANDS, chā'gōs (sometimes called OIL ISLANDS), a group of British-owned islands in the Indian Ocean, a dependency of Mauritius (q.v.), about 1,200 miles northeast of that island and about 250 miles south of the Maldives Islands. The group consists of five main coral atolls, with its center at latitude 6° 0' S and longitude 72° 0' E. However, Diego Garcia, largest member of the archipelago—about 2½ miles long and 6 miles wide—is 100 miles to the southeast. This island is crescent-shaped and consists of a coral atoll covered with cocoa palms, enclosing a lagoon that forms a harbor. During World War II it served as a British air base. The two other inhabited islands are Peros Banhos and Salomon; the uninhabited are Three Brothers and Six Islands. The surrounding waters teem with fish, and excellent green turtle are found on the shores. Coconut oil is the chief product, and copra, coconuts, fish, and guano are also exported. Pigs and poultry are raised. Pop. (1944) 1,048.

CHAGRES, chā'grís; Span. chā'grás, a river and village in the Panama Canal Zone. Founded at a site discovered by Columbus, the village (1950 pop., 210) stands at the Atlantic (Caribbean) mouth of the river, about 6 miles west-southwest of Colón. In the colonial period, it was the principal Atlantic port of the isthmus, but it is now of little significance. The river, which rises in the Republic of Panama (Cordillera de San Blas), is today largely merged with the Panama Canal and, particularly, Gatun Lake. See also PANAMA—*Chagres River*.

CHAGRIN FALLS, shā-grín', village, Ohio, Cuyahoga County, altitude 985 feet, on the 45-mile-long Chagrin River. It is served by the Wheeling and Lake Erie railroad, and is 16 miles by highway east of Cleveland. A largely residential community, with a mayor and council form of government, it also manufactures paper, chemicals, pharmaceuticals, electrical goods, and machinery. Pop. (1950) 3,085.

CHAHAR, chā'hār' (Chinese CH'Á-HA-ERH), formerly one of China's northern provinces. It was bounded on the north by Inner Mongolia, west by Suiyuan, southwest by Shansi, southeast by Hopeh, and east by Jehol. Lying mainly between two sections of the Great Wall, in the drainage basin of two rivers, the region is on a traditional trade route between China proper and Mongolia, on the Peking-Suiyuan railroad. Agriculture, stock raising, and coal and iron mining are also important. Kalgan (Wanchüan), formerly the capital, and Tatung, both on the railroad, are the two chief cities in the area; Tolum is a caravan center.

In 1914, Chahar was formed as a Mongol administrative area in the Mongolian Chahar League; in 1928 it became a full province. During the Sino-Japanese War, Chahar was occupied by the Japanese (1937–1945) and was a part of their Mongolian puppet state. In 1949 the Chinese Communists, who had gained control after World War II, made boundary changes in order to include a section of Chahar in the Inner Mongolian Autonomous Region. Chahar then included a northeast section, once part of Chihli Hopeh, and

a southwest section taken from North Shansi. It covered approximately 45,000 square miles; pop. (est. 1940) 3,500,000. The province was reported abolished in November 1952, along with Pinkiang Province, and partitioned among other provinces of North China.

CHAILLE-LONG, shá-yá'lǒng', Charles, United States soldier, diplomat, and explorer: b. Princess Anne, Somerset County, Md., July 2, 1842; d. Virginia Beach, Va., March 24, 1917. He attended Washington Academy in 1860, and enlisted in the Union Army in 1862, rising to the rank of captain. After the Civil War he joined (1869) the Egyptian Army as a lieutenant colonel, and was chief of staff to Gen. Charles George Gordon ("Chinese Gordon") in 1874-1877, while Gordon was engaged in suppressing slave traffic in the White Nile region. The khedive entrusted Chaillé-Long with a secret mission to the king of Uganda, and while on this mission, he carried out important explorations in the upper Nile basin. His experiences were told in his book: (*Central Africa: Naked Truths of Naked People* (1876)).

Returning to the United States, he took a law degree at Columbia University in 1880, and practiced in Alexandria, Egypt, acting there as United States consul general after the revolt of June 11, 1882. He later became consul general and secretary of the legation in Korea (1887-1889); secretary of the Universal Postal Congress, Washington, D.C., May 1897; and chargé d'affaires (October 1897-September 1898) of the special commission to the Paris Exposition of 1900. In 1910 he was awarded a gold medal by the American Geographical Society for his part in the final solution of the problem of the Nile sources. Chaillé-Long published in both French and English. Some of his works are *The Three Prophets: Chinese Gordon, Mohammed-Ahmed (El Maahdi), Arabi Pasha* (1884); *Les sources du Nil* (1891); *L'Égypte et ses provinces perdues* (1892); *La Corée ou Chosen* (1894); *Les provinces équatoriales d'Égypte* (1904); and *My Life in Four Continents* (1912).

CHAILLU, Paul du. See DU CHAILLU.

CHAIN, English chān, **Ernst Boris**, German-born, naturalized English biochemist: b. Berlin, Germany, June 19, 1906. Educated in his native city, he became a refugee from Nazism in 1933, and went to Cambridge, England, to join Sir Frederick Gowland Hopkins in research on enzymes and the isolation of biologically active substances. In 1935 he became a member of the faculty of the Sir William Dunn School of Pathology at Oxford, and in 1938 collaborated with Professor H. W. (later Sir Howard Walter) Florey at Oxford on a systematic investigation of antibiotic substances produced by bacteria and molds. This all-important work laid the foundation for the discovery of the chemotherapeutic properties of penicillin and Chain's discovery of penicillinase. With Sir Alexander Fleming and Florey he shared the Nobel Prize for physiology and medicine in 1945. Many other international medals and awards followed. After World War II, Dr. Chain became scientific director of the international research center for chemical microbiology in the Istituto superiore di Sanità, Rome, Italy. He was made a fellow of the Royal Society in 1949.

CHAIN ARMOR. See CHAIN MAIL.

CHAIN BRIDGE. See BRIDGE.

CHAIN CABLE. See CABLE.

CHAIN MAIL (more properly, "mail"), flexible armor of interlinked metal rings; also called chain armor, mail armor, and linked armor. The form and size of the rings, and the method of interlinking them, vary. In most European examples each link is riveted and passes through four others, the average ring being less than half

Method of making chain mail: Wire coiled around a cylinder (1) is cut into rings with overlapping ends (2) which are flattened (3), punched for a rivet (4), and riveted (5); typical riveted mail mesh (6) and section (7); stamped ring without joint (8); butted ring (9); coiled link (10); and link with cusped inner diameter (11).

an inch in outside diameter. However, there are examples with each ring linked through six others (rare); some with large and small rings in alternate rows (certain of the early Gaulish fragments are of this order); and many examples in which rows of solid rings, stamped out in one piece, alternate with rows of welded or riveted

Left: Chain mail as represented on Trajan's column (114 A.D.). Top right: English warrior (King Harold?) from Bayeux Tapestry wearing mail hauberk at Battle of Hastings (1066). Bottom right: Arming coif of quilted fabric worn under mail hood (From Maciejowski MS, mid-13th century).

rings. In some meshes (the so-called "double-mail") the rings are formed of heavier wire, thus diminishing their inside diameter sometimes to such an extent that even the point of a pin will not penetrate.

Mail was in use in Western Europe centuries before the Crusades but, except for scattered archaeological finds, examples earlier than the

Robinson-Patman Act, passed in 1936, was aimed specifically at monopolistic practices in distribution. Simultaneously, many independent enterprises have formed among themselves so-called voluntary chains, in which separately owned and managed stores pool their resources in such activities as joint wholesaling, buying, or promotion; and consumers have formed profit-sharing consumer cooperatives, which, particularly in European countries, often consist of large chains (see COOPERATIVE MOVEMENT).

The operation of more than one store has been considered by some students to constitute a chain, but it has been contended that some characteristics typical of chain store operation, especially in the food field, do not become operative until there is a minimum of four stores under a single ownership and operation. In spite of great changes in the size of stores, the key difference between independent operations and chain operations remains the number of stores under common ownership and management. Added stores mean added volume and the ability to warehouse merchandise sold in the retail outlets, instead of purchasing from a wholesaler; ability to purchase in larger quantities and to transfer merchandise to retail stores without the necessity of maintaining salesmen, or of dividing volume with two or more other wholesalers; ability to advertise jointly for a group of retail outlets; and ability to secure and use the services of experts in various fields, such as personnel selection and training, record controls, site selection, store design and layout, and so forth, and spread the fees commanded by these experts over a number of units. The result then is, besides greater efficiency, reduced prices because of lower costs and elimination of extra profits by the middleman.

History.—Chains of the retail distribution type have been found by historians as far back as ancient Rome and in China about 200 B.C. Chains were part of the commercial system of 17th century Japan, Germany, and England. In America, the Hudson's Bay Company, chartered in 1670, operated a famous chain of trading posts. This was the earliest chain known to have operated on this continent. Andrew Jackson at one time owned a small chain of retail stores in Tennessee. However, the first major development of the modern chain store in the United States began in 1859, when George F. Gilman and George H. Hartford opened a store for the sale of tea, coffee, and spices which they purchased as importers on the theory that they would eliminate some intervening costs and therefore be able to sell this merchandise at lower prices to customers. They found that this idea as practiced by their company, the Great American Tea Company, worked out as anticipated, and it was not long (1865) before they had expanded their operations to sell other grocery items in their chain which had grown to 25 stores. This, then, was the beginning of what became in 1869 the Great Atlantic and Pacific Tea Company, which in 1930 operated a peak number of 15,700 stores.

Chain stores soon were introduced in the clothing, book, cake, and restaurant fields, and for a great variety of other goods and services. In the following will be discussed three of the most representative types of chains: FOOD CHAINS, VARIETY CHAINS, and DRUG CHAINS.

FOOD CHAINS

The rise of the chain system in the United

States was closely linked with the development of food chains. The Great Atlantic and Pacific Tea Company was followed by such other multiple stores as the Grand Union Company (originally Jones Brothers Tea Company, 1872, New York); the Kroger Company (1882, Cincinnati); The American Stores Company (1886, Pennsylvania); H. C. Bohack Company (1887, New York); Gristede Brothers (1891, New York); First National Stores (1895, Boston); National Tea Company (1897, Chicago); Jewel Tea Company (1899, Chicago); Henke & Pillot (1872, Houston); Ralph's (1873, Los Angeles); Daniel Grocer Company (1882, Murphysboro, Ill.); and F. W. Albrecht Company (1891, Akron).

Legislation.—Nevertheless, in the food chain field, the period until the turn of the century was one of sporadic development. In the early years of the 20th century there was a substantial growth both in the number of food chain companies and in the number of stores operated. A little later, in the decade 1920 to 1930, there were a series of efforts to penalize the new chain store method of distribution by legislative measures. Anti-chain store tax laws were introduced in a number of state legislatures beginning in 1923, and at one time 29 states had discriminatory taxes against chains. In the 1930's the food chains launched an attack against anti-chain store tax proposals by presenting their case to the public, and the tide began to turn. Several of the discriminatory laws were declared unconstitutional, and in 1936 a California discriminatory tax was rejected by a referendum vote. Other states repealed similar tax laws until in late 1953 only 15 state anti-chain store tax laws remained in effect.

Profits.—Food chains, in 1953, operated with an average margin of about 18 per cent based on sale price. This covers warehousing and delivery, office operations, buying, advertising, and overhead, as well as all store labor, rent, light, heat, supplies, and other expenses. Average operating profit before taxes was reported by the National Association of Food Chains as 2.20 per cent for 1952, with estimated profit after taxes at an average of 1.0 per cent.

Supermarket and Self-Service.—A new development in food distribution, which began in the early 1930's with independent food stores, was quickly taken up by food chains and extended rapidly. This was the development of the so-called supermarket. As early as 1916, Clarence Saunders of Memphis, Tenn., conceived the idea of self-service in food stores on a broad scale. Isolated examples of self-service had appeared before this time, but the Piggly-Wiggly system developed by Mr. Saunders started self-service on its remarkable career. The system was built around a plan using turnstiles and guardrails which directed traffic past displays of merchandise on shelves and gondolas (tables) and then past check-out stands complete with cash registers. Early self-service stores generally limited the self-service feature to the dry grocery department.

The depression period of the early 1930's gave great impetus to the development of self-service and to the building of larger markets, with wider lines of merchandise, lower prices, free parking, a minimum of service features, and larger volume. Beginning about 1947, self-service was extended on a major scale to the meat department with pre-packaging of consumer meat cuts in transparent wrapping film. Pre-packaging of meat is done at the store in nearly all cases, although experiments

in centralized pre-packaging of meats are currently in progress. Pre-packaging of produce has been adopted almost universally for such items as tomatoes and spinach, and quite generally for potatoes, apples, oranges, carrots, and other fruits and vegetables, although many stores offer these items both pre-packaged and in bulk.

General Characteristics.—Some major features of chain food stores include: one price system—that is, all merchandise is marked so that each customer pays the same price for the same item; cash and carry, rather than credit and delivery; self-service, which is now being extended in many larger stores to dairy products, meats, and produce, as well as grocery items; full lines of merchandise, including some household items, which make possible so-called one-stop shopping; vastly improved sanitation, both in store and merchandise; parking facilities. Although all of these features are not available in all outlets of every chain, they are characteristic of the system as a whole.

Warehouse efficiencies, newly developed by food chains, include extensive use of mechanization in the physical handling of merchandise (fork-lift trucks, pallets, towlines, industrial tractors, and similar devices), and mechanization of accounting systems, including mechanical and electronic punch-card systems.

The percentage of retail food stores business done by food chains has remained relatively stable since 1933 when it was estimated that retail food chains did 38 per cent of the food store business. During the war years when food products were rationed, food chain percentage dropped, but for 1953 it was estimated by the National Association of Food Chains that the share was approximately 39 per cent. Leveling off of the percentage of total retail business done by food chains is due in major part to the great improvement in services rendered by the wholesaler-independent retailer system, and the development of cooperative chains and voluntary chains which have resulted in the adoption of many of the new methods developed by chains. Increasing numbers of single large-volume supermarkets have helped to maintain the independent share of total retail food store volume, but many successful single store operators open additional stores and thereby move into the chain store classification.

Reasons for the success of chain food stores were recently investigated by the National Association of Food Chains. Factors stressed by homemakers were: lower prices; wide variety; convenient location; courteous service; fresh, dependable merchandise; and cleanliness.

The influence of the American food chain system of distribution is being felt in other countries notably in Europe and South America, as a result of visits to the United States by operators of foreign food chains.

The concentrated merchandising ability of food chains has been used to relieve the pressure of agricultural surpluses by featuring plentiful foods as a service to both producer and consumer—and as good business for the chains. In 1936, the first nationwide campaign to sell farm surpluses was inaugurated by the National Association of Food Chains with 34,000 cooperating food stores giving special merchandising aid to peaches. Results were so startling that this became the forerunner of about 300 similar organized sales efforts. This organized program, which utilizes the united mass merchandising technique of food chains, was de-

veloped in a series of conferences between representative farm leaders and food chain executives through the machinery of the National Association of Food Chains.

Lower cost food distribution through chain stores has not only contributed to an improved standard of living but has made possible an expansion of food production with far-reaching effects. New products can be introduced much more rapidly with food chain advertising support based on the industry's expenditure of an estimated \$150 million a year in newspaper, radio, and television promotions. The impact of display in hundreds or even thousands of outlets at a time gives worthy new products a fast start toward consumer acceptance. Vast increase in use of refrigeration has extended the market for perishable products and made seasonal items available, in some cases, the year around.

JOHN A. LOGAN,
President, National Association of Food Chains.

VARIETY CHAINS

Frank W. Woolworth (q.v.) is generally credited with being the pioneer of the five and ten cent store. There is considerable evidence that several other men had experimented with the same idea even before Woolworth tried his one-price plan while working as a clerk in Augsburg & Moore's Dry Goods Store, Watertown, N. Y. But few dispute the fact that it was Woolworth who perfected this new concept of retailing, and did more than any other individual to popularize the variety store of today.

The success of five and ten cent stores has been due largely to the great variety of inexpensive, fixed-price merchandise made available; attractive presentation in open displays; top retail store locations; and the experience of shoppers that they get their money's worth.

Expansion.—Frank Woolworth opened his first successful five and ten cent store in 1879 at Lancaster, Pa. The five and ten idea expanded gradually in the beginning, gathering momentum as the new type of merchandising became more and more popular with the public. Following Woolworth, the McCrory Company started in 1881, S. H. Kress in 1896, S. S. Kresge in 1897, W. T. Grant and G. C. Murphy in 1906, Neisner Brothers in 1911, J. J. Newberry in 1912, and McLellan in 1913. The H. L. Green Company came into the field in 1932 as a consolidation of the profitable stores of the F. & W. Grand Stores (in business since 1901), the Metropolitan Chain Stores, I. Silver Brothers, and the F. & W. Grand-Silver Stores. The limited price variety store chains, or syndicate stores as they were originally called, had developed at a steady rate up to the World War I period.

Their greatest expansion to date came during the war years and through the prosperous 1920's. The companies named above, all of which started out as the ventures of independent merchants, operated the following numbers of stores in 1931, the year in which new store openings began to level off: Woolworth, 1,903; Kresge, 711; McCrory, 244; Newberry, 379; McLellan, 278; Neisner, 78; Murphy, 172; Grant, 404; and Kress, 221. As of the date of consolidation in 1932, the H. L. Green Company was operating 133 stores, which advanced to 182 by the next year and then remained relatively constant. Since 1931, expansion in respect to number of stores has been gradual for most companies.

CHAIN STORES

OUTLETS AND SALES OF VARIETY CHAINS

	Stores		Sales	
	1931	1952	1931	1952
F. W. Woolworth Co.	1,903	1,960	\$282,669,576	\$712,600,880
S. S. Kresge	711	691	145,785,473	324,173,813
W. T. Grant Co.	404	495	75,679,203	281,708,699
G. C. Murphy Co.	172	295	19,238,362	184,065,449
S. H. Kress & Co.	221	260	69,041,926	176,241,576
J. J. Newberry Co.	379	478	31,146,802	166,264,827
McCormick Stores Corp.	244	211	43,295,613	107,027,898
McLellan Stores Co.	278	233	21,945,688	63,830,513
Neisner Bros. Inc.	78	127	15,958,818	62,492,197
Totals	4,390	4,750	\$704,761,461	\$2,078,405,852

A comparison of the number of stores operated as of Dec. 31, 1952, with the number operated in 1931, reveals that in several instances national variety chains are operating considerably fewer stores today than twenty-odd years ago. But a comparison of their dollar sales shows that nine of these chains multiplied their combined sales from 1931 to 1952 almost three times.

A significant trend is the expansion that has taken place in the size of the stores operated. Even before World War II, there was a decided trend toward larger, so-called super stores, and since the end of the war all variety chains have been working on extensive remodeling and enlargement programs, with the result that the present day variety store is rapidly becoming one of the largest, best-looking stores in the shopping section of the average American city—barring perhaps only a relatively few department stores of the highest caliber.

The years from 1931 to 1952 saw the rapid growth of the regional or sectional variety chain. Companies like Hested Stores, of Nebraska; Elmore Stores, of Alabama; T. G. & Y. Stores, in Oklahoma; and Duckwall, in Kansas, all capitalized on the growing prosperity coming to the smaller towns as a result of decentralization of population. Three other variety chains—the Sprouse-Reitz Co., Inc., the Scott-Burr Stores Corporation, and Rose's 5-10-25¢ Stores, all of which now operate well over a hundred stores—also came of age during this period.

Current Market.—The following table for Dec. 31, 1952, lists sales, stores, and percentage of the total market for the national, regional, and local variety chains, with an estimate for single store operations:

TYPES OF VARIETY CHAINS, THEIR NUMBER AND SALES

Type of Operation	Chains	Stores	Sales	Per cent of total
Major United States variety chains, operating 100 or more stores (includes 314 Canadian stores)	13	5,522	\$2,266,979,303	72.2
Regional variety chains, operating 10 to 99 stores (includes 258 Canadian stores)	78	2,117	244,839,000	7.9
Local variety chains, operating 3 to 9 stores (includes 63 Canadian stores)	466	1,965	160,369,500	5.2
Two-store variety chains (includes 6 Canadian stores)	605	1,210	73,944,300	2.4
Single variety stores (includes 34 Canadian stores)	...	13,466	386,178,000	12.3
Total United States and Canada	162	24,280	\$3,132,310,103	100.0

A study of the above sales volumes and a comparison with 1931 sales must take into consideration the price inflations of World War II. In fact, the price inflations of World Wars I and II hit particularly hard at the traditional fixed five-and-ten cent price levels of variety chains. Although these stores continued to hold the line

on sizable quantities of nickel and dime merchandise, inflation forced many items into 15, 20, and 25 cent price brackets.

Increased Merchandise Assortments.—The heavy program of remodeling and enlarging existing stores is part of a carefully planned program of increasing merchandise assortments. To satisfy customer demands and to offset rising "cost-to-sell," variety chains have added not only many new lines of merchandise but also better quality and higher-priced lines to their former single popular-priced ones. In addition, to reduce expenses, most variety chains today are experimenting with variations of the grocery supermarket type of check out self-service. Most of these experiments have been confined to relatively low-volume stores.

Increased merchandise assortments and the dollar volume that each department produces are indicated in the table on the next page; the 1952 sales of the 24,280 stores given in the table below are listed according to categories of lines offered.

Variety Stores in Canada.—Among the largest operators of Canadian stores are three United States variety companies. The F. W. Woolworth Company, as of Dec. 31, 1952, was operating 165 stores in Canada. The S. S. Kresge Company operated 67 stores north of the border, and the H. L. Green Company controlled the 82 Metropolitan Stores in Canada. There are several hundred additional Canadian stores operated by Canadian companies, including such firms as People's 5, 10, 15¢ to \$100 Stores, Ltd.; United 5 cents to \$1.00 Stores, Ltd.; Stedman Brothers, Ltd.; R. A. Beamish Stores, Ltd.; and Zellers, Ltd. The last-named company is affiliated with the W. T. Grant chain.

Variety Stores in Great Britain.—The F. W. Woolworth Company operates a chain of approximately 780 stores throughout the British Isles, in addition to which there are many other variety stores operated by British interests.

Variety Stores on the European Continent.—The F. W. Woolworth Company was operating

TYPES OF GOODS AND SALES

Merchandise Lines	Sales, 1952
Apparel and accessories	\$ 824,424,019
Dry goods and domestics	240,958,346
Notions and smallwares	219,261,707
Hardware, paints, electrical supplies, appliances, etc.	231,164,486
Home furnishings	229,911,562
Drugs and toiletries	197,335,536
Toys, games, and books	278,149,137
Stationery	251,837,732
Jewelry	59,827,123
Soda fountains, luncheonettes, and restaurants	202,034,002
Confectionery and nuts	186,059,220
All other lines	202,347,233
Total	\$3,132,310,103

approximately 46 variety stores in West Germany as of Dec. 31, 1952. German interests operate variety stores in both the eastern and western sectors.

The variety store idea has also found acceptance in France, Sweden, Belgium, and Czechoslovakia, and five-and-ten's or close approximations of them operate in India, China, and other parts of the Far East. South America, too, has its chains of five-and-ten cent stores, the most outstanding of which are the *Lojas Americanas* in Brazil. The Woolworth Company operates stores in Cuba, and the S. H. Kress Company has several sizable units in Hawaii.

DRUG CHAINS

History.—A dozen or more drug chains in operation in the mid-1950's can trace their beginnings to parent stores established prior to 1900. Among them (with the year of their founding) are: Schlegel Drug Stores, Davenport, Iowa (1850); Meyer Bros. Co., Fort Wayne, Ind. (1852); T. P. Taylor & Co., Louisville, Ky. (1879); Jacobs Pharmacy Co., Atlanta, Ga. (1879); Dow Drug Co., Cincinnati, Ohio (1882); Read Drug & Chemical Co., Baltimore, Md. (1883); Marshall Drug Co., Cleveland, Ohio (1884); Skillern's Drug Stores, Dallas, Texas (1885); Kinsel Drug Co., Detroit, Mich. (1888); Cunningham Drug Stores, Detroit (1889); Bartell Drug Co., Seattle, Wash. (1890); Owl Drug Co., San Francisco, Calif. (1892); Eckerd Drug Stores, Erie, Pa. (1898); and Standard Drug Stores, Cleveland (1899). But none of these companies had shown any growth as a chain by the turn of the century. Indeed, the total number of chain drug stores in existence at that time probably did not exceed 75.

Between 1900 and 1910 several additional chains were founded, including some which were destined to become leaders in their field. Among them were Hook Drugs, Indianapolis, Ind. (1900); Dockum Drug Stores, Wichita, Kans. (1900); Walgreen Co., Chicago, Ill. (1901); Peoples Drug Stores, Washington, D.C. (1905); Louis K. Liggett Co., New York (1907); Mading's Drug Stores, Houston, Texas (1907); Katz & Besthoff, New Orleans, La. (1908); and Gallaher Drug Co., Dayton, Ohio (1909).

But it was not until after 1920, when the chains began to expand spectacularly in all fields, that the drug chains likewise showed their greatest growth. What happened in the case of two of

today's leading drug chains reflects the general expansion trend between 1920 and 1930 and the tapering off which marked the years which followed. With 19 stores in 1920, the Walgreen Co. grew to 419 by 1930, an increase of 2,100 per cent. By 1938, it was operating 508 stores, but from then on, following the general trend toward bigger but fewer stores, it reduced its total number of stores to the present level of 406. Peoples Drug Stores similarly grew from 8 stores in 1920 to 117 in 1930, an increase of 1,360 per cent, and although this company now operates 151 stores, its growth since 1930 has been at a much slower rate.

Mid-Century Status.—The United States had in the early 1950's approximately 54,000 drug stores, with aggregate sales close to \$4,500,000,000 annually. Of these stores, some 7,700, or 14 per cent, were chain stores—that is to say, they were owned and operated by companies which had at least two stores, as contrasted with the remaining 46,000 drug stores each of which was operated by a single-store proprietor. Of the total sales, the chains accounted for some \$1,300,000,000, or 29 per cent, annually.

This overall statistical picture tends to obscure the fact that in many of the larger cities of the United States, chain drug stores enjoy the bulk of the available business, since chain drug stores are concentrated largely in urban areas. Not only do they operate relatively more units in the larger cities than they do nationally, but the stores are bigger and have a much larger average volume than the average drug store. The current trend towards shopping centers finds the drug chains operating the drug stores in most of them.

Merchandising Characteristics.—Like most other kinds of chains, the drug chains operate largely on a cash and carry basis, although their units in suburban areas may make deliveries and extend credit in some instances. Because they escape the cost of credit and delivery and enjoy the other advantages which flow from operating a number of stores instead of just one, the drug chains originally found it both feasible and desirable to emphasize their lower prices. Featuring many standard products below the regular price, the drug chains gained recognition as outstanding exponents of cut-price or "loss-leader" merchandising, even though they were by no means the originators of that promotional device nor the only merchants to use it.

However, with the decline in consumer buying-power resulting from the depression in the early 1930's, the drug chains found cut-price merchandising far less attractive than it had previously seemed. The situation was aggravated by the appearance of a new type of proprietary stores, referred to in the trade as "pineboards." These newcomers featured nationally advertised products at deep-cut prices which the chains were in no position to meet.

It was then that the drug chains joined their independent competitors in condemning ruthless price-cutting and favoring legislation to end it. Ever since that period, the drug chains have been ardent advocates of the fair trade laws which currently prevail in 44 states. These laws permit manufacturers of branded products to establish minimum retail prices which are binding on all retailers who deal in them whether they have agreed to abide by such prices or not. Although the fair trade laws have eliminated the use of standard products as "loss leaders" in the drug field, the drug chains have maintained their posi-

tion as aggressive merchandisers in other categories.

Chain drug stores are not only bigger than their predecessors but handle a much broader range of non-drug lines. Despite this trend, however, they have not overlooked the importance of the exclusive franchise they enjoy as registered pharmacies. Their prescription departments are conspicuously placed and pharmaceuticals are actively merchandised. The soda fountain and luncheonette, in which drug stores pioneered, continues as an important feature of modern drug chain operation. See also DRUG TRADE.

CHAINS AND CHAIN MAKING. A

chain consists of a series of similar links which either interlock or are joined to each other so that they form a continuous flexible metal line. The chain is one of the most familiar as well as one of the most useful of mechanical devices. Its origin is undoubtedly very ancient; remnants of excellent Roman chains may be found in the museums of the world. The uses of chain are many, but the three principal uses are for the hoisting of materials, for the transmission of power, and for the conveying of materials. Chains are also used as surveyors' measures, as ornaments, as restraints, as elevator counterweights, and in many other ways too numerous to mention.

All chains may be divided into two general classes which receive their names from the fundamental forms of the links. Coil chains consist of series of links, generally oval in shape, which interlock by passing through one another. Block chains consist, fundamentally, of flat bars which are joined together by cylindrical pins so that the bars are free to articulate about the pins. Coil chains are sometimes loosely called crane chains from the fact that they are generally used in connection with cranes. Block chains are sometimes called link chains, pitch chains, and sprocket chains. Coil chains may be subdivided into open link chains, studded link chains, twisted link chains, safety chains, ladder chains, and jack chains, while block chains may be subdivided into simple block chains, multiple block (leaf) chains, silent chains, detachable chains, and pintle chains.

Open link chains are composed of series of interlocking oval links. The links of such chains are generally made from round bars, the size of the chain being taken as the diameter of the bar from which the links are made. The most common example of an open link chain is the ordinary crane hoisting chain. The links of studded link chains are similar to those of open link chain, being provided, in addition, with studs or braces across the centers of the links. These studs strengthen the links, enabling such chains to carry safely loads 20 to 25 per cent in excess of those which may be safely carried by open link chains of

the same dimensions. Twisted link chains are made up of links similar to those of open link chains which have been twisted through an angle of 90 degrees. Safety, ladder, and jack chains are of minor importance. The first is made up of small flat links which are stamped from sheet metal; the latter two consist of twisted interlocking wire links.

Simple block chains consist of single series of flat bars, each having round holes near its ends, which are joined together by means of pins, rivets or bolts which pass through these holes. The ordinary bicycle chain is, perhaps, the most common example of such a chain. Multiple block chains or leaf chains consist of series of flat bars, similar to those which compose simple block chains, which are placed side by side upon the same pins. A chain of this type has the general appearance of a number of bicycle chains joined side by side. Silent chains are of the multiple block type, being made up of series of flat bars which have profiles on one side much like gear teeth in appearance. Chains of this type operate over sprocket wheels which look very much like spur gears. Roller chains are essentially block chains in which the flat bars have been separated to allow the introduction of a roller between them. Detachable chains are composed of rectangular links which interlock by sliding over one another. This interlocking of the links eliminates the necessity of using pins for joining them. Pintle chains are made up of U-shaped links which have barrels at one end and which are joined by means of pins in the form of either rivets or bolts. Chains are generally made of wrought iron, steel, or malleable iron. When they are subject to excessive corrosion, brass, bronze, or some other corrosion-resisting material may be used.

Chains used as ornaments are generally made of brass, bronze, or the precious metals. Chains used as ships' cables and for hoisting are almost exclusively made of wrought iron, for the ductility and toughness of wrought iron, together with its excellent welding properties, make its use desirable despite its comparatively low tensile strength. The iron used is a specially rolled grade, of high tensile strength and great ductility, the object being to secure a chain which, on the application of a sudden stress—as, for instance, when a ship is riding at anchor in a heavy seaway—will stretch and so resist the strain gradually, instead of snapping, as would be liable to happen with material of higher tensile strength but small ductility or power of elongation. The small sizes of coil chain are sometimes made of steel but, in general, such chains are inferior to those made of wrought iron. Simple block chains, multiple block chains, and silent chains are usually made of mild steel provided, generally, with hardened steel bushings and pins. One or two types of silent chains are equipped with rocker joints which obviate the necessity of using bushings. Roller chains are made of steel and of malleable iron. Roller chains made of steel are similar in construction to block chains. Those made of malleable iron are generally provided with cast iron rollers. Detachable and pintle chains are made, almost exclusively, of malleable iron because of the peculiar form of the links which makes it economical to cast them, although of late many of the smaller sizes of detachable chain have been made from steel on automatic punching presses. The links of pintle chains are sometimes provided with case hardened renewable bushings.

The pins for joining the links of pintle chains are usually steel.

Coil chains of the open, studded, or twisted link type are usually handmade. Many of the smaller sizes—up to $\frac{3}{8}$ -inch—are made on automatic machines, while chains above two inches are made with the aid of power presses and steam hammers. Whether made by hand, by automatic machinery, or with the aid of power presses and steam hammers, the same operations are involved. The bar from which the links are to be made is first cut up into pieces long enough to make single links; the ends of each of these pieces are next scarfed and bent so that when the link is formed the scarfed ends will come together; the scarfed piece is next formed into the shape of the finished link; the formed links are then drawn through the last link of the finished chain and its ends are welded. In making studded or twisted link chain, the additional operation of placing the stud or twisting the link is necessary. These operations are generally performed after the link has been welded. The weld is usually located at the end of the link.

In the smaller sizes the whole operation of chain-making by hand is done by a single smith without any helper. The length of completed chain is hung upon a hook or some convenient support near the anvil, and the operation of forging the link proceeds as follows: In his fire the smith will have two or three short rods of the required diameter, and as one is heated to, say, a cherry red, he withdraws it, cuts off the desired length for one link, gives it a couple of blows to form the welding scarf, bends it through, say, about 130 degrees, hooks it into the end of the completed chain, and brings the ends together for welding. He then raises the link to a welding heat in his fire, places the abutting ends over what is known as the bick-iron, gives it a few taps to ensure a good weld, brings over a "dolly" (which is hinged at the outer end of his anvil and when brought over registers above the bick-iron), and with half a dozen blows on the dolly, accompanied by a dexterous movement of the link, the weld is completed and the link smoothed up to a neat finish. The rapidity with which the smiths do this work is very remarkable. Thus, in the case of a $\frac{7}{8}$ -inch chain, with 30 links to the yard, an expert smith will cut off from the iron bar, scarf, bend up into shape, and weld the links, at the rate of 18 yards in a day or approximately one link per minute.

In forging heavy chain two helpers are used, the iron is cut to about one-foot lengths, and several of these are heated in the fire at the same time. The operation is as follows, the various steps succeeding each other with great rapidity: First, the helper to the right of the anvil withdraws the heated piece, drops one end into an eye at the end of the anvil, and bearing down upon the tongs, bends the piece over to an angle of about 45 degrees. The smith then takes it in his tongs, and with a few taps of the sledge it is bent around. It is heated again, passed through the end of the chain by the smith, and laid flat on the anvil, and the welding scarfs are put on with a few blows of the sledge. The link is now raised to a welding heat, welded with a few blows by the helpers, and laid over the bick-iron; the hinged dolly is brought over, and a few rapid blows on the dolly, while the smith turns the link to and fro, serve to bring the weld up to a smooth

finish. The link is now laid on edge; a single blow from the sledge brings it into shape, and with a final tap or two of the smith's hammer the link is finished. At this forge as many as 35 links will be added to a $1\frac{1}{4}$ -inch chain in one hour, or about one every two minutes.

One type of machine making coil chains winds the bar from which the chain is made upon a mandrel in the form of a spiral much similar to a spring. Each loop of the spiral is then cut apart at an angle of 60 degrees so as to form a scarf, and is welded in a set of dies under a drop hammer operated by a workman. Another type of machinery automatically performs all of the operations, including the welding, taking in a plain round bar and turning out a finished, assembly chain. Weldless chains up to one inch have been made with some success by passing a red hot cruciform bar through a series of machines. The first operation consists of impressing the outer form of the links on the bar. The second operation cuts away the webs which join the links, and the third breaks the links apart and finishes the chain. Coil chain larger than 2-inch can be made entirely by hand only at a tremendous expense of severe labor and time and it is virtually impracticable to attempt to make such chains without the use of power presses for forming the links and steam hammers for welding them. Chains smaller than 2-inch which are made by hand are generally superior to those made by machinery, while beyond 2-inch machine-made chains, after proper annealing, are by far both stronger and more uniform.

Ladder, jack, and similar weldless chains are made by machines which automatically cut off the wire, form the links, interlock them and twist or bend the ends of the links together. Chains of this type can only be made in small sizes and can be used for only unimportant work such as for horse halters, fences, dog chains and the transmission of hand power. Chains made of precious metal are generally made by machinery in a manner analogous to that used in making iron coil chains, except that the links are either left open or are closed by brazing instead of welding. Very often the links of such chains are stamped and brazed by hand. The operations involved in the manufacture of block chains are few and simple. The bars from which simple and multiple block chains, silent chains, and steel roller chains are made are stamped from metal bars of the required width and thickness, the holes for the pins being generally punched while the links are being stamped. In the case of extremely accurate chains, the holes are drilled and the links are finished and polished. The pins of chains of this type are either drop forged, cold rolled, or machine turned. The rollers of roller chains intended for light duty are made of pipe or tubing cut to proper length. For severe duty it is necessary to use rollers which are made by boring out solid shafting. Chains of these types are assembled by hand, usually with the assistance of a small power hammer for forming the rivet heads.

The links of malleable iron detachable and pintle chains are cast and annealed in the usual manner. After annealing, the links are thoroughly cleaned by tumbling and are then assembled to form the finished chain. Some of the smaller sizes of detachable chain are assembled by machines, all of the larger sizes being assembled by hand. All pintle chains are hand assembled with

the aid, when the chain pins are riveted, of small power hammers for upsetting the heads of the rivets. All chains which are to be used for important work are tested after manufacture in order to eliminate the defective links. This is done by subjecting them to test loads well above those under which they are to work and cutting out all links which exhibit defects. Chains which operate over sprocket wheels are also tested for accuracy of pitch and are well oiled and well limbered up before being shipped.

Chains used to hoist materials are generally of the coil type—open link chains being most commonly used. In unusual cases and under peculiar conditions block chains have been used for this work. Chains used for ship's cables are of either the open link or the studded link type. Chains for this duty have been made from bars as large as four inches in diameter. Chains for the transmission of power are generally of the simple block, multiple block, roller, silent, or pintle types. For low speeds, simple and multiple block and pintle chains are most satisfactory; for medium speeds, roller chains are used; for high speeds, silent chains are usually employed. Small sized coil chains are frequently used for the transmission of hand power. Chains for the conveying of materials are generally of the simple block, roller, detachable, or pintle type, although long pitch, open link coil chains were formerly quite extensively used for this work. Chains which convey materials are generally equipped with attachments which serve to carry buckets, flights, aprons, etc., which actually do the conveying. Block chains for the conveying of materials are made with pins up to three inches in diameter and in pitches up to three feet.

Surveyor's chains are open link chains of peculiar construction. The links are relatively long and the ends, instead of being welded, are joined by means of small circular links. A "chain" consists of 100 links, which aggregate 100 feet in the United States and 66 feet in England.

Although each coil chain link consists of two thicknesses of bar, it must not be presumed that a chain possesses double the strength of a single bar; actually there is a reduction of three-tenths in the strength, due to the formation into links, so that the chain has but about seven-tenths of the united strength of two bars of the same diameter of iron. Moreover, as the strength per square inch of a heavy bar is not so great as that of a smaller diameter iron, a further reduction is to be made on this account.

The chain industry is not confined to any one particular country or any one locality. The complete absence of statistics makes it impossible even to approximate its extent.

Technical data on chains may be found in various standard works on machine design and engineering.

CHAIR, an article of furniture consisting of a seat supported by legs, a back, and sometimes arms. One of the oldest furniture forms, the chair for centuries connoted authority or importance, ordinary people being seated on stools or benches. Even today we use "the chair" in parliamentary procedure and "chairman" for one who presides, and speak of a college or university professorship as a "chair."

The oldest chairs extant are Egyptian. Found in tombs, they are of wood, metal, or carved

ivory, and of two types, four-legged and X-shaped. In the former, the legs are carved, ending in animal feet; the seats are solid, or of latticed strapping or woven rush; and the backs are paneled, and attached to solid arms, carved and gilded. The X-shaped ones were originally covered with whole skins. Both types have also been excavated at Nineveh. Chairs of ancient Greece have not survived, and are known only from Greek sculptures and literature; the *thronos* was the chair of authority. Surviving examples show that the Romans had elaborately-made chairs of wood, metal, or ivory, provided with silk-covered cushions. Their X-shaped curule chair was the official seat of magistrates and others in authority. Their *cathedra*, a chair with a back, was used by women.

The scant furniture of the early Middle Ages included no chairs except those of Byzantine provenance. The Chair of Saint Peter (q.v.) at the Vatican is 6th century Byzantine. It is wood overlaid with ivory, and its carving depicts the labors of Hercules. Later, a ruler usually possessed an architectural, paneled chair placed on a dais, with surmounting canopy. Use of chairs in Renaissance Italy was more general. The Roman curule inspired the Savonarola type, but the typical Italian armchair had four legs, a frame ornamented with carving, and an upholstered seat and back. The France of Francis I (r. 1515-1547) copied these but made them more comfortable. During the Louis XIV (r. 1643-1715) period, craftsmen evolved the *fauteuil* and *berçère*, which became graceful and delicate in the Louis XV (r. 1715-1774) period. Springs came into use and fabrics replaced leather.

In England, French designs were followed but considerably adapted. Basic Gothic structure persisted until the Restoration, when cabriole legs became dominant, and lasted through the Chippendale period. After 1770, the classic revival, introduced by the brothers Adam, prevailed. Chair legs were slender, square, and tapering. They became turned and reeded in the Regency years, and other lines were less angular. During the early years of the Victorian age, chairs reverted to continuously curved lines. The Eastlake Gothic resulted in such designs as the Morris chair with adjustable back and thick cushions. American chairs (1650-1850) copied and adapted English designs. With the Windsor and banister back, craftsmen materially enhanced the beauty of line and decorative detail. The rocking chair, sole American original contribution, is credited to Benjamin Franklin and resulted in the Boston Rocker. Outstanding among American chairs are those by Duncan Phyfe (q.v.) and John Henry Belter. Modern furniture design, with its stress on simplicity of line and functionalism, has resulted in chairs of molded plywood and bent metal tubing designed primarily for comfort. See also FURNITURE.

THOMAS H. ORMSBEE.

CHAIR OF SAINT PETER, The, a chair known as *Cathedra Petri*, preserved at the Vatican in Rome. Although its origin is obscure, it is believed by Roman Catholic authorities to have been used by St. Peter in the Santa Prisca Church outside Rome, and removed to Rome by Pope Damascus I in the 4th century. An ancient wooden chair, it was ornamented with ivory and gold, and enclosed in bronze by Pope Alexander VII (1655-1677), who had it placed above the altar in St. Peter's Cathedral. There it remained

for 200 years, but in 1867 it was exposed for the veneration of the faithful by Pope Pius IX. It was then revealed to be a carrying-chair such as was used in ancient Rome. The feast of *Cathedra Petri* is celebrated in the Vatican on February 22.

The name Chair of St. Peter or *Cathedra Petri* is also used to denote the See of Rome or the office of the papacy, from the tradition that St. Peter was the first bishop of Rome.

CHAIREDDIN or **KHAIR-ED-DIN**. See **BARBAROSSA**—**BARBAROSSA II**.

CHAISE, shāz; (1) a two-wheeled carriage for two persons, with a calash top, usually drawn by one horse; (2) any light carriage such as a post chaise; (3) a French gold coin or *chaise d'or* issued by Louis IX in the 13th century. It took its name from the representation of the seated king on the face of the coin. Chaises were also coined in England in the reign of Edward III.

CHAITANYA or **CAITANYA**, chī-tūn'yā, early 16th century Hindu mystic. See also **INDIA**—*Religion and Philosophy*.

CHAKA, chá'ká, a powerful Zulu ruler and conqueror (1773–1828). See also **DINGAAN**; **ZULU LAND**.

CHAKRI, chāk'krē, Siamese (Thailand) dynasty. See also **THAILAND**—*P'ya Takh Sin and The First Chakri Rulers*.

CHALCANTHITE, kál-kán'thīt, native hydrated sulphate of copper, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$; also called blue vitriol or bluestone. It occurs in triclinic crystals, and in stalactitic or reniform masses; sometimes fibrous or granular. It is dark blue, translucent, vitreous, brittle, and readily soluble in water, and has a disagreeable metallic taste. The hardness is 2.5 and the specific gravity ranges between 2.12 and 2.30. It is found in Chile; Cornwall, England; Spain; and in many copper-mining localities in the United States, where it is frequently deposited from mine waters.

CHALCEDON, kál'sé-dón, or **CHALCHEDON**, kál'kě-dón, an ancient city (modern KADIKÖY, q.v., in Turkey) of Bithynia, Asia Minor, on the Bosphorus opposite Byzantium (now Istanbul) and at the entrance of the Euxine Sea or Black Sea, located about two miles south of Scutari (now Uskudar). Chalcedon is said to have been founded 17 years before Byzantium, about 677 B.C., by Greek colonists from Megara. Less favorably situated than the latter city, it was also called in antiquity "City of the Blind." Nevertheless, it flourished in trade, and finally joined the Athenian League when the Greek cities freed themselves from Persian rule in 389 B.C. Chalcedon was an important township when it was bequeathed to the Romans, along with the rest of Bithynia, by Nicomedes III in 74 B.C. By giving it to Rome, Nicomedes had hoped to keep it safe from Mithridates, but the latter followed the Romans to Chalcedon, destroyed the fortifications of the port, and burned or captured their ships. About 616 A.D. it was captured by Khosrau (Chosroës) II of Persia, and in 1075 it was destroyed by the Turks. Its site is now occupied by the city of Kadiköy, virtually a suburb of Istanbul.

At Chalcedon in 451 A.D. (October 8 to Novem-

ber 1), the emperor of the East, Marcian, summoned the fourth general (oecumenical) council of the church—known in ecclesiastical history as Council of Chalcedon—for the purpose of eradicating the Monophysite doctrines which had prevailed under the influence of Dioscurus, the patriarch of Alexandria, and of Eutyches (q.v.) since the so-called Robber Synod (Council) at Ephesus in 449. The aim of the Council of Chalcedon, therefore, was to define the Christian faith so as to guard its orthodoxy against the Nestorian and Monophysite heresies. The council opened under the guidance of Paschasinus, the bishop of Lilybaeum (Marsala), acting as deputy of Pope Leo I. About 600 bishops, mostly from the East, were present. The bishops of the West were largely prevented from coming because of the activities of Attila the Hun.

The sessions were held outside the city, in the Church of St. Euphemia, which was later destroyed by Suleiman, who built a mosque in its place. The council deposed Dioscurus; and after a violent debate settled upon the articles of faith, declaring, in opposition to the Monophysites, the doctrine of the two natures of Christ, existing without mixture or change, without division or separation, so that by the union of the two natures in one person and substance their distinction is not destroyed, but the characteristics of each are retained. The controversy, however, continued. Besides this creed, the council promulgated 30 canons against clerical abuses, of which the 28th conceded to the See of Constantinople (Byzantium) rights and privileges second only to the Roman See; but Pope Leo I refused to confirm this decree.

Rebellions in Palestine, Egypt, and other Near Eastern countries (where Monophysites still survive today) were the immediate consequences of these decrees of the council, and not until after a long period of ecclesiastical controversy did the Chalcedon formula obtain the undisputed authority which it now has in the Roman Catholic, Greek Orthodox, and in many Protestant churches. See also **EUTYCHIANISM**.

CHALCEDONY or **CALCEDONY**, kál-séd'ō-nī, a silica mineral named for Chalcedon, an ancient Greek town of Asia Minor. It is a cryptocrystalline variety of quartz, semitransparent to translucent, with a waxy luster, and white, gray, blue, brown, or black in color, but commonly of a tint suggestive of diluted milk, marked with veins, spots, or circles. It occurs in masses, also very frequently in mammillary, botryoid, and stalactitic forms. It is used for ornament, and is often called "white agate." There are several varieties, such as common chalcedony, chrysoprase, prase, carnelian, onyx, agate, jasper, flint, sard, sardonix, plasma, heliotrope (blood stone), and moss agate (mocha stone). The crystals of chalcedony are so minute that their structure is visible only through a microscope.

CHALCEDONYX, kál-séd'ō-nīks, semiprecious stone. The name applies to those agates in which opaque white chalcedony alternates with the translucent gray variety.

CHALCHIHUITL, chāl-chī-wē't'l, or **CHALCHUITE**, chāl'chōō-it, a blue or green mineral, highly valued by the Aztecs of Mexico, who worked it into gems. It was extracted in what is today New Mexico.

CHALCHUAPA, chäl-chwä'pä, city, Salvador, in Santa Ana Department, about 8 miles west of Santa Ana, with which it is linked by rail and highway. It is a coffee center, also noted for the pre-Columbian ruins in its vicinity. Chalchuapa was the site of a battle (1885) in which the president of Guatemala, Justo Rufino Barrios, fell. Pop. (1950) 9,855.

CHALCID FLIES, a group of parasitic Hymenoptera included in the superfamily Chalcidoidea, most of which are beneficial because they attack other insects which are injurious to plant life, although a number attack plants. A good many are looked upon as pests because they are parasitic upon their own parasitic relatives and other beneficial parasites. The vast majority are extremely small and the group includes *Alapetus magnanimus*, about $\frac{1}{400}$ of an inch long, which is believed to be the smallest insect. The largest member of the group is the American *Pelecinus polyturator*, a blue black species, with long thread-like abdomen, the female of which attains a length of more than two inches. The larvae are parasitic on white grubs of the Coleopterous family Scarabaeidae. The superfamily is divided into 18 families, which exhibit a great divergence of habits. They may be phytophagous, and some are gallmakers or parasitic upon gallmakers. In many of the families there are species which are parasitic upon the eggs of other insects: the females are able to puncture the shell of the egg and deposit an egg within, without injury to the attacked egg. One of the best known of these is *Tetrastichus asparagi*, the larvae of which develop in the eggs of asparagus beetles. *T. bruchophagi* is a parasite of the clover seed chalcid. In addition to attacking eggs, the larvae also develop in the larvae, pupae, and adults of Lepidoptera, beetles, bugs, and other insects. Several species, such as *Prestinidica aquatica*, swim under water to locate the eggs of damselflies, beetles, and bugs. On the whole, the group is beneficial.

CHALCIDICE, käl-sid'i-sē (Greek KHALKIDIKE, käl-kyē-thē-kyē'), peninsula, eastern Macedonia, Greece, projecting into the Aegean Sea in three promontories, now called Pallene or Kassandra, Sithonia, and Akte—the latter the site of Mt. Athos. In the 6th and 7th centuries B.C., two tribes, Chalcidians and Bottiaei, with settlers from Greece proper, colonized the peninsula. Olynthus and Potidaea were the chief towns on the isthmus of Pallene (Kassandra); Scione and Mende were on the southwest of Pallene; Torone on the southwest part of Sithonia. The colonists supplied timber and wines to Greece.

After the Persian Wars, in 479 B.C., Chalcidice joined the confederation of Delos, but in 424 B.C. Olynthus and several other towns were freed from Athens by Brasidas, and others became independent in 404. The Chalcidian cities under the leadership of Olynthus and Potidaea formed a league, disbanded after a siege by the Spartans (379 B.C.), and again reformed. They joined the Second Athenian League, but withdrew in 371 and fell to Philip II of Macedon (r. 359–336 B.C.), who enslaved and transplanted many of the inhabitants, repopling the peninsula with Macedonian veterans. In the 2d century B.C. it fell to Rome.

In its modern form the peninsula is divided into the departments of Salonika and Chalcidice. The city of Salonika (Thessalonika) is at its northern base.

CHALCIS, käl'sis, or **CHALKIS**, käl'kis (Greek KHALKIS, Käl-kyēs'), capital of the island and department of Euboea, located at the junction of the Atalante and Ey(u)ripos channels. The latter is narrowed to 85 feet at Chalcis by a rock, surmounted by a castle, partly of Venetian, partly of Turkish origin. The main channel, 120 feet wide, was once crossed by a drawbridge which has been removed in clearing and widening the channel for larger vessels. The city is one of the most attractive in Greece, consisting of an inner walled town and an outer or suburban portion, the walls being the work of the Venetians. In the inner town the streets are narrow and the houses lofty. Several of the churches were formerly mosques. The modern town is a rail terminus and trading center for wines, cereals, livestock, olives, figs, and citrus.

Ancient Chalcis was one of the greatest Ionian cities. It carried on a large trade, and planted numerous colonies in Macedonia, Italy, Sicily, and the islands of the Aegean Sea. The Chalcians joined the Boeotians (Thebans) in a war with Athens, in which they were defeated (506 B.C.). A series of revolts against Athens ended in 411 B.C. in a short period of independence. The city was subsequently occupied by the Macedonians, and eventually fell under the yoke of Rome, which made it a place of great military importance. In Roman times it was nearly nine miles in circumference, and contained temples, theaters, and other public buildings. Chalcis was the birthplace of the orator Isaeus and the poet Lycophron; and Aristotle died here. The city was partly destroyed when the citizens joined the Achaeans in their last war with Rome (146 B.C.). It was afterward rebuilt, and at the beginning of the Christian era was the chief city of Euboea, temporarily known as EVRIPOS. The Venetians, who called it NEGROPONT (Negroponte), held it from 1209 A.D. to 1470, when it was taken by the Turks. In 1833 it became part of the kingdom of Greece. The Germans occupied the city in World War II (1941). Pop. (1951) 26,097.

CHALCIS FLIES. See **CHALCID FLIES.**

CHALCOCITE, käl'kō-sīt (from Greek *chalkós*, copper), a native sulphide of copper having the formula Cu_2S . It crystallizes in the orthorhombic system, though it usually occurs in massive and sometimes granular forms. Its hardness ranges from 2.5 to 3, and its specific gravity from 5.5 to 5.8. Opaque and leaden in color, it has a metallic luster. In the United States it occurs in crystals at Bristol, Conn.; massive as the principal copper ore at Butte, Mont., and in many copper mines in Arizona and other southwestern states and in Southwest Africa, Spain, Mexico, Chile and Peru. Beautiful crystals come from Cornwall, England. The mineral contains 80 per cent of copper, ranking as a source of copper next in importance to chalcopyrite (q.v.). Chalcocite is known also as copper glance, chalcocin, and redruthite (from the town of Redruth in Cornwall).

CHALCONDYLES, käl-kōn'di-lēs, or **CHALCOCONDYLAS**, käl-kō-kōn'di-lās, Demetrius, Greek scholar: b. Athens about 1424; d. Milan, Italy, 1511. Like his teacher Teodoro Gaza, the Greek scholar, he went to Italy to teach the Greek language and literature. His first patron there was Cardinal Johannes Bessarion, him-

self a Greek. Later, about 1479, he was asked by Lorenzo de' Medici to come to Florence, and in 1492 was invited by Lodovico Sforza to Milan. Chalcondyles played a prominent part in the classical revival in Italy, spreading the study of Greek in western Europe through the many scholars he trained, among them Johann Reuchlin, the German humanist. Besides a Greek grammar entitled *Erotemata* (?1493) he published editions of Homer, Isocrates, and Suidas, which are somewhat arbitrary in the emendations of the text.

His brother LAONICUS CHALCONDYLES (d. 1464), after witnessing the fall of Constantinople, where he was ambassador of the ruler of the Eastern Roman Empire, followed Demetrius to Italy, and wrote a valuable history of the last years of the Byzantine Empire (from 1298 to 1463) in ten volumes.

CHALCOPYRITE, *kāl-kō-p'rit* (from Greek *chalkós*, copper), a native sulphide of copper and iron, also called copper pyrite, having the formula CuFeS_2 or $\text{Cu}_3\text{S} \cdot \text{Fe}_2\text{S}_3$. It crystallizes in the tetragonal system, commonly with a tetrahedral aspect. Chalcopyrite is brasslike in appearance, and is often tarnished and iridescent. It has a specific gravity of 4.1 to 4.3 and a hardness ranging from 3.5 to 4. The mineral is widely distributed in the United States (Montana, Arizona, New Mexico, and Utah) and constitutes the chief copper ore in Cornwall, England. Other deposits are at Sudbury, Canada; Riotinto, Spain; Falun, Sweden; and in Chile. Because of its iridescence it is often called "peacock ore." Chalcopyrite is softer and deeper in color than ordinary iron pyrites, with which it is often confused.

CHALDEA or CHALDAEA, *kāl-dē'ā*, in ancient geography originally only the southerly part of Babylonia (q.v.), toward Arabia and the Persian Gulf, lying along the then separate mouths of the Tigris and Euphrates rivers. In the Bible it came to be synonymous with all of Babylonia. The Chaldeans are supposed to have been at first a nomadic Semitic people hailing from Arabia, but they later became settled and finally secured the throne of Babylonia in 625 B.C. They helped to bring about the fall of the Assyrian Empire in 612 B.C., and in 597 and 586 B.C., under Nebuchadnezzar II, subdued Judaea and captured Jerusalem. Their name was transferred to the Babylonian Empire, but was dropped when the Persians captured Babylon in 539 B.C. The name Chaldean was especially applied by the author of *Daniel*, Herodotus, and other writers of antiquity, to some of the Babylonian magi, who were devoted to the pursuit of astrology and magical science.

CHALDEAN CHRISTIANS. See NESTORIANISM.

CHALDEE MS., The, a skit at the expense of a rival publisher, Archibald Constable, and of the Edinburgh notables associated with the Whig paper, the *Edinburgh Review*, and published in the seventh number of the new Tory publication, *Blackwood's Magazine*, October 1817. It was written in the form of an alleged biblical narrative in four chapters, by James Hogg, the "Ettrick Shepherd," whose original paper was greatly enlarged and modified by John Wilson ("Christopher North") and John Lockhart.

CHALET, *shā-lā'* (French for "little cas-

tle"), the Alpine houses of Switzerland and the adjacent regions of France, Bavaria, and the Austrian Tirol. It is a French-Swiss name, which is applied to modest huts as well as to picturesque villas built of timber in a unique style, chiefly distinguished by a low overhanging roof, elaborate woodwork, and the frequent use of balconies.

CHALEUR BAY, *shā-lōōr'* (Fr. BAIE DE CHALEUR, *bād' shā-lūr'*), an ocean inlet, Canada, in the western part of the Gulf of St. Lawrence, between the Gaspé Peninsula in southeast Quebec Province and New Brunswick. It is a submerged valley of the Restigouche River which flows into it. About 85 miles long from east to west, it has a maximum width of over 20 miles, and a depth of 250 feet. It was discovered by the explorer Jacques Cartier in 1535. The bay has a number of islands, notably Shippegan near its mouth. Navigation is good, and mackerel, cod, and salmon fishing are carried on. In 1760 the French fleet was defeated here by the British.

CHALFONTE SAINT GILES, *chāl'fünd-sünt-jilz'*, village, England, in southeast Buckinghamshire, seven miles east of High Wycombe, within Amersham rural district. Listed in the *Domesday Book* as Celfunte, it is an old town, quite unspoiled, and has on its main street the cottage where John Milton lived during the great plague and where he finished *Paradise Lost*. The cottage is now owned by the National Trust and is open to the public. Not far away is the little village of Jordans, where there is a charming old Quaker meeting place in whose cemetery William Penn is buried. Pop. (1951) 2,882.

CHALGRIN, *shāl-grän'*, Jean François Thérèse, French architect: b. Paris, 1739; d. there, Jan. 20, 1811. A student of Giovanni Niccolò (Jean Nicolas) Servandoni in Paris, he won the Grand Prix de Rome in 1758, and became a member of the academy of architecture in 1770. His Italian studies awakened in him a passion for the simple lines of classical Greek architecture, which are reflected in most of his work. On his return to Paris, Chalgrin built the Palace Lavrillière (now de Rothschild), reconstructed the church of St. Sulpice, and designed the church of St. Philippe-du-Roule. In addition, he executed major alterations on the Collège de France and the Palace de Luxembourg; but he is best known for his plans for the Arc de Triomphe de l'Étoile which was begun under his supervision in 1806, though completed long after his death, during the reign of Louis Philippe.

CHALGROVE, *chāl'grōv*, village, England, located in south Oxfordshire, nine miles southeast of Oxford. It is the site of a famous victory (1643) of the Royalists under Prince Rupert over the Parliamentarians under John Hampden, who was mortally wounded here, though he died at nearby Thame. An obelisk marks the spot where Hampden fell. The village church goes back to the 12th century. Pop. (1951) 388.

CHALIAPIN, *shū-lyā'pyin*, Fyodor Ivanovich (Russ. SHALYAPIN), Russian operatic basso: b. Kazan, Russia, February 1873; d. Paris, France, April 12, 1938. At one time or other, before seriously taking up the study of music, he was a cobbler, pawnbroker's assistant, carpenter, and government clerk. His musical career began as

choirboy in Kazan. Later he joined a traveling light opera company, and was stranded at Tbilisi (Tiflis) where the singer Usatov (Oussatov) offered to train his voice. He made his operatic debut in Tbilisi in Mikhail I. Glinka's *A Life for the Czar* in 1892.

In 1894 he left Tbilisi and sang at various theaters in Moscow and St. Petersburg (now Leningrad). He joined a private opera company in 1896, and appeared in many roles, notably that of Ivan the Terrible in the first production of Nikolai A. Rimski-Korsakov's *The Maid of Pskov* (*Psokovitianka*); in 1898 he achieved one of his greatest successes in *Boris Godunov*, Rimski-Korsakov's revision of Modest P. Musorgski's opera. Chaliapin also sang in Milan (first in 1901), Paris, and Monte Carlo. His soaring international fame owed as much to his acting ability and fine carriage as to his remarkable voice. Among the most celebrated roles of his career were the title roles in Rimski-Korsakov's *Ivan the Terrible*, in Arrigo Boito's *Mefistofele*, and in *Boris Godunov*.

Chaliapin's debut in London came under Sir Thomas Beecham in the Russian opera season of 1913-1914, when he triumphed in *Boris Godunov*, *Prince Igor*, and *La Khorunshchina*. Heading the Mariensky Theater, he remained in Russia during World War I until 1921 when he appeared for a time in London. He had visited the United States to sing at the Metropolitan Opera, New York, in the 1907-1908 season, but was then little noticed; returning in 1922 to replace Enrico Caruso as leading singer, he received undivided acclaim, particularly for Boris in *Boris Godunov* and Mephistopheles in Charles François Gounod's *Faust*. Another of his renowned parts was in Jules Émile Frédéric Massenet's *Don Quichotte*, a work specially written for him.

Though he made occasional appearances in Russia and the European countries, Chaliapin now sang mainly with the Chicago and New York opera companies until his last performance at the Metropolitan on March 20, 1929. In 1927 the Soviet government had deprived him of his title "Artist of the People" and had confiscated his estates, whereupon he left his native country for good. When later he was invited to return and sing, he refused, and became a French citizen, making his home henceforth in Paris. Chaliapin's reputation as the greatest singing actor of his day was now well established, and audience and reviewers marveled at his superb characterizations and magnetic personality. In 1934 he enacted the title role in the French motion picture *Don Quichotte*. His last appearance on the stage was in 1935, though he made a brief concert tour in the Far East in 1936. Two of the songs he popularized were the *Song of the Volga Boatmen* and *The Song of the Flea*. He wrote two autobiographic volumes, *Pages From My Life* (1927) and *Man and Mask* (1932).

CHALICE, chāl'is (from Lat. *calix*, cup), the sacred vessel of the Christian churches in which the consecrated wine is administered at the Eucharist, the ceremony of the Communion. It symbolizes the cup used at the Last Supper and is the emblem of many saints, particularly of St. John the Evangelist.

The early Christians at first used plain glass chalices, but later decorated them with goldleaf. Some authorities say that wood was the first material used. As it advanced from poverty the

church made the vessel of horn, then of ivory, and later of precious metals. Chalices of bone were used in Germany, but this material was forbidden in 787.

Chalices were classified by the clergy as *ministeriumales*, used for distributing the wine to large numbers on holidays like Easter; and *offertorii*, used on ordinary occasions. The former usually had handles (*calices ansati*), as they were quite large and heavy.

The ecclesiastical chalice is made up of three parts: the cup or bowl; the stem with its middle swelled into a bulb or other protuberance (termed a knob) to prevent its slipping when held; and the foot. In very early times, the paten—the vessel which holds the consecrated bread—was likewise termed a chalice.

From altar depictions of the 6th to 9th centuries it may be assumed that the earliest chalices were of the Greek cantharus shape. Next appeared a form similar to that of the present day, but much larger. For example, it is said that Charlemagne (r. 768-814) presented St. Peter's at Rome with a pure gold chalice weighing 53 pounds. After the 12th century chalices became smaller, losing their handles, and the bowls became conical or semiovoid. Wine was distributed from the large chalices through a small pipe (*fistula* or *calamus*) of gold, silver, or ivory,

A modern chalice.

which had one or more handles. Examples of such types are still extant.

Chalices may also be divided into the following classes: pontifical chalices for use on festive occasions; those used at common mass; "traveling" chalices for use when visiting distant places—usually small and frequently in parts that could be separated and packed into a small compass; and funeral chalices, generally of lead or other common metal, for burial with bishops.

Wilfred Joseph Cripps, a noted authority on the subject, groups chalices into the following period types: (1) Norman (about 1170-1350), with circular feet; (2) Gothic (about 1350-1510), with hexagonal feet and conical bowls, and later (1490-1510) feet with toes; (3) Tudor (about 1510-1536), with six-lobed, flowing feet and bowls often less conical or nearly hemispherical.

Octavius Morgan, another expert, tells us that the feet were made out of the round (usually hexagonal) to prevent the chalice from rolling when laid upon its side to drain. Fine enamel and chased work usually appear on the knob, stem, and foot, frequently representing the Passion or other sacred subjects. One side may have a cross, which the officiating priest keeps facing him. The bowl is generally quite plain and highly polished, so as to be easily kept clean.

An example of a very fine early chalice may

be seen at The Cloisters, a branch of the Metropolitan Museum of Art, in Fort Tryon Park, New York City.

CHALICOTHERE, kăl'ī-kō-thēr, a mammal of the extinct family Chalicotheriidae of the Perissodactyla, found fossilized in various parts of the Northern Hemisphere from the Eocene epoch onward. It disappeared toward the close of the Miocene epoch in America and Europe, but persisted in southern Asia and in Africa, at least into the middle of the Pleistocene. Among the better known genera are *Pernatherium*, *Eomoropus*, *Moropus*, *Schizotherium*, *Macrotherium*, *Chalicotherium*, and *Ancylotherium*. They were fairly large forest-dwelling animals, perhaps resembling horses in form, with the teeth of a hoofed animal, but long burrowing claws like those of a rodent. The problem of their habits and mode of life is still unsolved, but it is inferred that they fed chiefly on leaves. Remains of *Moropus* were found at Agate Springs, Nebr.

Consult Scott, William Berryman, *Land Mammals in the Western Hemisphere* (New York 1913); and Romer, A. S., *Vertebrate Paleontology*, new ed. (Chicago 1950).

CHALIER, shāl'yā, (Marie) Joseph, French revolutionist: b. Beaulard, Dauphiné, France, 1747; d. Lyon, 1793. Although educated for the church, he engaged in business instead, and traveled for a Lyon firm in Spain, Portugal, Italy, and the Middle East. At the outbreak of the French Revolution in 1789, he was in Paris, and associated himself with Maximilien Robespierre, Jean Paul Marat, and Camille Desmoulins. Returning to Lyon he became (1791) the first member of the municipal bureau, and led in the civic reorganization that ensued; and his administration was approved in the face of criticism in the Legislative Assembly. In 1792, however, Chaliere was defeated by a Royalist in an election for mayor of Lyon. He became a leader of the local Jacobins, and in 1793 precipitated a conflict which ended in his arrest and sentencing by the tribunal of Rhône-et-Loire. He was guillotined, notwithstanding stay proceedings in the National Convention.

CHALK, chók, in geology a soft, friable, finely granular variety of limestone, composed principally of carbonate of lime (calcite or calcium carbonate), frequently with a small admixture of clay minerals, and in some chalks such as those in southern England, with nodules of silica, flint, or chert. Its color ranges from pure white to grayish and buff.

Chalk is a marine deposit, largely consisting of shells of minute organisms, Foraminifera, as well as other fossils. The name of the Cretaceous, in which chalk occurs, is from the Latin *creta*, chalk, referring to the beds early studied in Europe. Cretaceous chalk forms the cliffs of Dover along the English Channel. Chalk in the Cenomanian, Turonian, and Senonian stages of the geological system extends from Flamborough Head, Yorkshire, on the east coast to Dorset on the south. Similar Upper Cretaceous chalk forms a ring around the Paris Basin in France and appears interruptedly northward to Denmark. The best known chalk formations in North America belong also to the Upper Cretaceous. On the coast of the Gulf of Mexico, a chalk belt extends for hundreds of miles northeast and southwest from Austin, Texas, a few hundred feet thick at

the surface, and continuing beneath the surface toward the Gulf. Similar chalk crops out in Alabama, and in the northern Mexican states of Chihuahua, Coahuila, and Tamaulipas. Chalk of about the same age, generally called Niobrara, is found in Kansas and Nebraska, and westward in Colorado and Wyoming.

Chalk is widely used as one of the principal constituents in the making of cement. It forms an important source of agricultural limestone, and is burned for quicklime. Beds that are more indurated are called limestone, which in many regions is used as building stone. In smaller quantities, and after purification, chalk is used as whitening in cleaning substances (specially for metalware), rubber materials, and putty, and to allay stomach acidity. The common chalk of the schoolroom is a manufactured substance, not generally made from natural chalk. See also CALCITE; CALCIUM; CEMENT; CRETACEOUS; and LIMESTONE.

CHALK RIVER, village, southeast Ontario, Canada, on the Chalk River—flowing nearby into the Ottawa River—95 miles west-northwest of Ottawa. It is the site of a government research station operated by the National Research Council of Canada for Atomic Energy and has an atomic pile of heavy water, established in 1947.

CHALKE, khāl'kē, Greek island of the Dodecanese.

CHALKHILL, chók'hil, John, English poet: fl. ?1600. Known as the author of the pastoral *Thealma and Clearchus*, published in 1683 with an introduction dated five years earlier—by Izaak Walton. Walton also included two of Chalkhill's songs in the *Compleat Angler*. Virtually nothing is known about his life, though he has been tentatively identified with Ivon or Ion Chalkhill, a coroner of Middlesex County. His poetry was reprinted in George Saintsbury's *Minor Caroline Poets*, vol. 2 (London 1906).

CHALKLEY, chók'klē, Thomas, Anglo-American Quaker: b. Southwark, England, May 3, 1675; d. Tortola, Virgin Islands, Nov. 4, 1741. He went to Virginia in 1698, visited the Puritan settlements, and in 1701 bought land in Philadelphia. Besides engaging in profitable trade there, he went on extensive trading and preaching tours that took him to Barbados, various parts of the American colonies, and later to England, Scotland, the Netherlands, and Germany. His interesting experiences were recorded by him in his highly readable *Journal*, which was frequently reprinted in England.

CHALLEMEL-LACOUR, shál-mēl'-lā-kōor', Paul Armand, French statesman and philosopher: b. Avranches, Manche, France, May 19, 1827; d. Paris, Oct. 26, 1896. Having graduated from the École Normale Supérieure in 1894, he became a professor in the schools of Pau and Limoges. When he protested against the coup d'état (1851) of Napoleon III, he was imprisoned and then exiled. Fleeing to Belgium and afterwards to Switzerland, he taught French literature at the Federal Institute of Technology, Zurich (1856-1859). Upon his return to France in 1859 he wrote prolifically for the reviews, and gained the confidence of the republican parties. In 1870 he was appointed prefect of the Rhône

Department; two years later he became a deputy to the National Assembly, and he was elected senator in 1876. From 1879 he was ambassador, successively, to Switzerland, Russia, and England; minister of foreign affairs in 1883; and in 1893 president of the Senate. In the latter year he was elected to the French Academy.

A friend of Léon Gambetta, Challengel-Lacour was noted as one of the foremost orators on the French political scene. He also wrote penetrating philosophical studies, among them *La philosophie individualiste* (1864), a work on Wilhelm von Humboldt, and *Études et réflexions d'un pessimiste* (1901).

CHALLENGER, chă'lin-ür, **Frederick Sproston**, Canadian artist: b. Whetstone, Middlesex, England, July 7, 1869. Although his family moved to Canada when he was a child, he returned to England for his education, then studied art at the Ontario School of Art, Toronto, in 1883-1884 under George Agnew Reid, and completed his training abroad. Challenger became a full academician of the Royal Canadian Academy in 1899, serving for six years on its council. He was awarded medals at the Pan-American Exposition in 1901 at Buffalo and at the Louisiana Purchase Exposition in 1904. From 1921 to 1924 he was an instructor at the Central Technical School at Toronto; and at the British Empire Exhibition at Wembley, England, in 1924-1925, he was a member of the jury of the Canadian art section. Some of his paintings are *Fathers of Confederation* at the Ontario Parliament Buildings, Toronto; *Harvest, A Song at Twilight, Wild Steeds of the Prairie, A Selkirk Pioneer, Aphrodite's Realm*, and *The Evening Breeze*. His mural work appears in hotels, theaters, and public buildings in Canada.

CHALLENGE, in law, an objection or exception, particularly a formal expression of opposition to a juror. Challenges may be made to either grand or petit jurors. Exceptions to the entire panel of jurors are called "challenges to the array," while objections to individual jurors are known as "challenges to the polls." The latter class are divided into "challenges for cause" and "peremptory challenges" for which no cause is required. As a general rule, there is no limit to the number of challenges for cause which are permitted. The number of peremptory challenges is regulated by statute in all civil actions and in most criminal cases.

Either party has the right, in both civil and criminal cases, to have the jurors sworn and examined as to their qualifications. This procedure, called *voir dire* examination, is subject to the discretion of the court. The grounds for a challenge for cause, usually specified by statute, are either lack of general qualifications for jury duty, or the existence of particular factors making the juror unfit to serve in the case on trial. Typical grounds are bias or prejudice, pecuniary interest in the litigation, prior formation or expression of an opinion on the case, and relationship to one of the parties.

The right to question jurors on the *voir dire* is generally held to include the eliciting of facts on which to base a peremptory challenge, as well as to demonstrate grounds for a challenge for cause. The right of peremptory challenge in civil cases did not exist at common law, but has been expressly conferred by statute in most jurisdictions.

In criminal cases, the defendant's right of peremptory challenge was narrowly limited at common law to trials for felonies, or for crimes subject to capital punishment. The prosecution had no right of peremptory challenge at common law, except in very early times, when the crown's right of peremptory challenge was unlimited. Most jurisdictions have expressly provided by statute for peremptory challenges in criminal cases by both the accused and the prosecution thereof.

In both civil and criminal cases, the number of peremptory challenges varies in different jurisdictions. In criminal cases, the number is ordinarily regulated according to the nature of the offense and the severity of the punishment which may be imposed for it. In federal criminal cases, for example, the number of challenges varies according to the extent of the punishment to which conviction of the offense charged may subject the accused, the maximum number being twenty challenges to each side, when the offense is punishable by death. If there are two or more defendants, the court may allow the defendants additional peremptory challenges, permitting them to be exercised either separately or jointly. In federal civil cases, each party is entitled to three peremptory challenges, a group of plaintiffs or defendants being generally treated as a single party for such purpose. The right to challenge members of courts martial and military courts of inquiry is governed in the United States by the provisions of the Uniform Code of Military Justice, enacted in 1950.

RICHARD L. HIRSHBERG.

CHALLENGER EXPEDITION, a long cruise conducted from Dec. 7, 1872 to May 24, 1876 under the auspices of the British government for the purpose of exploring the open ocean. H.M.S. *Challenger*, a corvette of 2,306 tons, was fitted with a great variety of appliances for scientific research, and placed in command of Captain George Strong Nares. Professor C. Wyville Thomson headed a scientific staff of six naturalists, among them John Murray and Henry Nottidge Moseley, who conducted investigations to determine the depth of waters, the configuration and conditions of the sea floor, the marine fauna, the temperatures and compositions of sea water, the ocean currents, atmospheric conditions, and other data.

After leaving Sheerness, Kent, England, the expedition spent a year in the Atlantic, and in October 1873 reached Capetown, South Africa, going on then to Australia, Japan, and Hawaii, then to the west coast of South America, and through the Strait of Magellan back to England, disembarking at Spithead near Portsmouth. The *Challenger* was the first steamship to cross the Antarctic Circle. On their return to England, Nares, Thomson, and Murray were all knighted. They had traveled 68,890 nautical miles and made soundings at 362 stations. The material they collected took many years to study. Thomson died in 1882, and Sir John Murray completed the report, which was gradually published in 50 volumes (London 1880-1895). The narrative of the expedition is told in more popular form in Dr. Henry Nottidge Moseley's *Notes by a Naturalist on the Challenger*, 2d ed. (London 1892), a work that for its scientific importance and literary charm has been compared to Charles Darwin's *Journal of the Cruise of the Beagle*.

CHALLIS, chāl'is, James, English astronomer: b. Braintree, Essex, England, Dec. 12, 1803; d. Cambridge, Dec. 3, 1882. Educated at Trinity College, Cambridge, he became a scholar there in 1824 and was elected Plumian professor of astronomy and experimental philosophy in 1836, assuming also the direction of the observatory. In 1861 he gave up the latter position, but retained the professorship of astronomy until his death. He is probably best known for his work on astronomical instruments, and for his observations in connection with the discovery of the planet Neptune, based on Urbain Jean Joseph Leverrier's investigations of the disturbed motions of Uranus. The discovery of Neptune was, however, announced (1846) in Berlin, before Challis was able to draw the final conclusions from his own research, which had actually noted the position of Neptune a few weeks earlier.

Equally significant for Challis' stature as a scientist was his ambition to account for all physical phenomena in a unified mathematical theory of science. His inventions include the collimating eyepiece, a transit reducer, and a meteoroscope. He contributed some 225 essays to publications, and wrote in addition several books on astronomy, mathematics, and physics.

CHALLONER, chāl'ō-nēr, Richard, English Roman Catholic prelate: b. Lewes, England, Sept. 29, 1691; d. London, Jan. 12, 1781. Though his father was a Protestant dissenter, he was brought up in the Catholic Church to which his mother belonged. At the age of 13 he entered the English college at Douai in France, and after completing his studies, was made professor of rhetoric and philosophy there (1713), ordained (1716) priest, and later appointed vice president of the college (1720) and professor of divinity. He remained at Douai until 1730, when he was sent to London to preach and make converts. An anti-Catholic treatise by Dr. Conyers Middleton drew him into a heated controversy and he had to withdraw from England for a few months.

In 1740 he was consecrated bishop of Debra and coadjutor to the vicar apostolic of London, and he succeeded to the vicariate in 1758. Among Challoner's varied writings are the devotional *The Garden of the Soul* (probably 1740), still in general use among Roman Catholics as a prayer book. He wrote also *Memoirs of Missionary Priests . . . from the Year 1577 to 1684*, 2 vols. (1741-1742). His revision of the Douai-Reims English version of the Old and New Testament appeared under the title *The Rheims New Testament and the Douay Bible, with annotations*, 5 vols. (London 1749-1750). His translation of Thomas a Kempis's *Imitation of Christ* was widely circulated.

Consult Trappes-Lomax, M., *Bishop Challoner, derived from Dr. Edwin Burton's The Life and Times of Bishop Challoner* (New York 1936).

CHALMERS, chā'mēr-z, Alexander, Scottish journalist and biographer: b. Aberdeen, Scotland, March 29, 1759; d. London, England, Dec. 10, 1834. Son of the founder of the first Aberdeen newspaper, he received a classical and medical education in his native city, and about 1777 went to London, where he became editor of the *Public Ledger* and *London Packet*, and a contributor to the *St. James's Chronicle*, the *Morning Chronicle*, the *Morning Herald*, and various critical magazines and reviews. In addition, Chalmers edited

the works of a number of English authors, including Henry Fielding, Samuel Johnson, Alexander Pope, Edward Gibbon, and Lord Bolingbroke (Henry St. John); and published an edition of Shakespeare with historical and explanatory notes (1809). He also published a *Glossary to Shakespeare* (1797). Of particular merit are *The British Essayists, with prefaces, historical and biographical, and a general index*, 45 vols. (1803), commencing with the *Tatler* and ending with the *Observer*; and *The English Poets from Chaucer to Cowper* (1810), an expanded version of Samuel Johnson's *Lives of the Poets*. Also among his literary labors was the *General Biographical Dictionary*, 32 vols. (1812-1817), the fullest body of biographical information published up to his time in England, which has rendered valuable service to subsequent compilers and students.

CHALMERS, George, Scottish antiquary: b. Fochabers, Moray, Scotland, 1742; d. London, England, May 31, 1825. Having studied law at Edinburgh, he went to Maryland in 1763, and practiced as a lawyer in Baltimore for 10 years until the American Revolution. Being a strong Loyalist, Chalmers returned to Great Britain, where in 1786 he was appointed clerk to the privy council for trade. Previous to this appointment he had published *Political Annals of the present United Colonies from the Settlement to the Peace of 1768* (1780); *An Estimate of the Comparative Strength of Great Britain during the present and four preceding Reigns* (1782); and *Opinions on Interesting Subjects of Public Laws and Commercial Policy Arising from American Independence* (1784). In 1790 he published a biography of Daniel Defoe. He also produced other biographies—among them one of Thomas Paine (1793) under the pseudonym of Francis Oldys—and edited the works of several Scottish writers, including Thomas Rudiman, Allan Ramsay, and Sir David Lindsay (Lyndsay of the Mount). The first volume of his *Caledonia* (1807) displayed vast erudition. Planned as a historical and topographical account of Scotland from the earliest to modern times, the second and third volumes appeared in 1820 and 1824, but the work was still unfinished when Chalmers died. He also wrote a *Life of Mary Queen of Scots* (1818), and left manuscripts for histories of Scottish poetry and printing.

CHALMERS, George Paul, Scottish painter: b. Montrose, Scotland, 1836; d. Edinburgh, Feb. 20, 1878. After serving under an apothecary and a ship chandler, he went to Edinburgh in 1853 to study painting under Robert Scott Lauder. The first picture he exhibited was *A Boy's Head*, done in chalk. Elected to the Royal Scottish Academy in 1867, he was made a full member four years later. His pictures, characterized by rich coloring, were at first mainly portraits, but the landscapes he produced later are now valued more highly. Among his canvases are *End of the Harvest* (1873); *Running Water* (1875); *Prayer* (1876); *Knitting* (1876); and the unfinished *The Legend* (in the National Gallery, Edinburgh, Scotland).

CHALMERS, James, Scottish bookseller: b. Arbroath, Angus, Scotland, Feb. 2, 1782; d. Dundee, Aug. 26, 1853. Taking a keen interest in public affairs, he played a part in post office

reforms. In 1834 he introduced adhesive postal stamps, an invention usually attributed to Sir Rowland Hill, who, however, gained acceptance for his project without knowing of Chalmers's previous efforts.

CHALMERS, James, Scottish missionary: b. Ardrishaig, Argyll, Scotland, Aug. 4, 1841; d. Goaribari Island, April 8, 1901. After early mission service in Glasgow, he was sent by the London Missionary Society to Rarotonga, Cook Islands, in the South Pacific in 1866. The natives came to be greatly devoted to him, and after ten years' enthusiastic work he received a more rigorous assignment among the savages of New Guinea, where he made many valuable explorations in the course of his missionary work. In 1890 he visited Samoa and met Robert Louis Stevenson, who wrote of him appreciatively. In 1901, with a brother missionary, Oliver C. Tomkins, he was killed by cannibals at Goaribari Island. Chalmers wrote *Work and Adventure in New Guinea* (1885); *Pioneering in New Guinea* (1887); and *Pioneer Life and Work in New Guinea* (1895). Consult also the posthumous *James Chalmers: his Autobiography and Letters* (1902).

CHALMERS, Sir Mackenzie Dalzell, British judge and parliamentary counsel: b. Nonington, Kent, England, Feb. 7, 1847; d. London, Dec. 22, 1927. Educated at King's College, London, and Trinity College, Oxford, he was called to the bar in 1869 and joined the civil service in India, where he served until 1872 and again from 1896 to 1898. Besides practicing law, he held public office as legal counsel, member of royal commissions, and judge, becoming first parliamentary counsel in 1902 and permanent under-secretary of state for the Home Department in 1903. Chalmers drafted important parliamentary acts pertaining to bills of exchange (passed 1882), sale of goods (passed 1894), and marine insurance (passed 1906). Among his writings is *Local Government* (1883).

CHALMERS, Thomas, Scottish theologian and social reformer: b. Anstruther, Fife, Scotland, March 17, 1780; d. Morningside, near Edinburgh, May 30-31, 1847. At the University of St. Andrews, where he was sent to study for the church, he became as much interested in mathematics as in divinity. In July 1799 he was licensed as a preacher, the rule of the Scottish church that a licentiate be 21 years of age dispensed with in his case, by virtue of his "rare and singular qualities."

In May 1803 he took up his duties at the parish of Kilmeny in Fife, and at the same time taught classes in mathematics and chemistry in the town of St. Andrews. He published *An Inquiry into the Extent and Stability of Natural Resources* in 1808, and in 1813 his notable article on Christianity appeared in the *Edinburgh Encyclopedia*. By that year his fame as a preacher had extended throughout Scotland, and the town council of Glasgow elected him to the charge of Tron parish, where he was inducted in 1815. In November he began a series of astronomical discourses which created a sensation and achieved a large sale when published in 1817. They made Chalmers the first preacher of his day, and when he went to London to lecture, the most distinguished statesmen and men of letters went to

hear him. Chalmers was also deeply concerned with the alleviation of poverty, for which he advocated voluntary charity instead of tax-paid public relief. His sociopolitical theories are formulated in *Political Economy in Connexion with the Moral State and Moral Prospects of Society*, 2 vols. (1832).

In 1823 he was elected to the chair of moral philosophy at St. Andrews, and in 1828 he accepted the chair of divinity in the University of Edinburgh, which he held until the disruption of the Established Church of Scotland in 1843. On this occasion he led the evangelical section in its withdrawal from the General Assembly, and is thus regarded as the founder of the Free Church of Scotland. He headed the Free Church College at Edinburgh from 1843 until his death. The social and religious movements he inaugurated left their mark far beyond the bounds of his own country. In his last years he completed the *Institutes of Theology*, his religious chef-d'œuvre. His extensive writings, ranging from natural theology, apologetics, and moral philosophy, to scientific, economic, and social subjects, were collected in 25 volumes during his lifetime. His son-in-law, William Hanna, published *Memoirs of the Life and Writings of Thomas Chalmers*, 4 vols. (1849-1852) and edited the *Posthumous Works of Dr. Chalmers*, 9 vols. (1847-1849).

Consult Watt, H., *Thomas Chalmers and the Disruption* (London 1943).

CHALMERS, chāl'mērzh, Thomas Hardie, American baritone, actor, and film producer: b. New York, N. Y., Oct. 20, 1884. After studying voice in New York, he went to Florence, Italy, in 1909, to study with Lombardi, and made his operatic debut as Marcello in *La Bohème* by Giacomo Puccini at Fossombrone, April 1911. He first sang in the United States with the Henry Savage Opera Company as Jack Rance in Puccini's *Girl of the Golden West* in 1911. After singing with other opera companies he made his debut at the Metropolitan Opera in December 1917 as Valentine in Charles François Gounod's *Faust*. Because of throat trouble which required an operation, he gave up his operatic career in 1922 and turned to the dramatic stage, appearing in Henrik Ibsen's *The Wild Duck* and other plays. From 1927 to 1938 he turned to motion pictures as a newsreel editor and producer of documentaries. Later he acted in such plays as *All My Sons* and *Death of a Salesman*.

CHALMETTE NATIONAL HISTORICAL PARK, shāl-mēt', just south of New Orleans, La., covers about 30 acres. The historical park commemorates the Battle of New Orleans, Jan. 8, 1815, when Andrew Jackson defeated the British (See NEW ORLEANS, BATTLE OF.) It consists of two sections, one of which includes part of the area where the battle was fought; some of the best works of the American line may still be seen there as well as the Chalmette Monument (begun 1855, completed 1908), a marble shaft approximately 100 feet high. The other section is occupied by the Chalmette National Cemetery (established 1861) with the graves of 14,000 Union soldiers.

Chalmette National Historical Park is named for its former owner, Ignace de Lino de Chalmette, who, although 60 years of age, reported for active duty to the American commander in the War of 1812. His own home had to be burned as

a war measure. The park was set up in 1907 as Chalmette Monument and Grounds, receiving its present name and status in 1939.

The adjoining village of Chalmette in St. Bernard parish on the east bank of the Mississippi has one of the largest sugar refineries in the world and manufactures petroleum products and oilfield equipment. Pop. (1950) 1,695.

CHALON, shā-lōn', Alfred Edward, English painter, younger brother of John James Chalon: b. Geneva, Switzerland, Feb. 15, 1780; d. Kensington, London, England, Oct. 3, 1860. Of French-Huguenot family, who settled in England in 1789, he joined his brother and others in founding the "Evening Sketching Society" in 1808. He won renown as a portrait painter in water colors and in 1816 he became a full member of the Royal Academy. Chalon was the first to paint a portrait of Queen Victoria after she acceded to the throne. An admirer of Jean Antoine Watteau, he also painted many canvases in oil, among them *Hunt the Slipper* (1831); *John Knox Reproving the Ladies of Queen Mary's Court* (1837), and *Sophia Western* (1857). Other works include a portrait of *Bulwer-Lytton* and illustrations for the novels of Sir Walter Scott.

CHALON, John James, English painter, brother of the former: b. Geneva, March 27, 1778; d. Kensington, England, Nov. 14, 1854. His family destined him for a career in business, but he early turned to art and studied at the Royal Academy in 1796. The first picture he exhibited was *Banditti at their Repast* (1800); another, *Napoleon on Board the Bellerophon* (1816), bequeathed to Greenwich Hospital, is probably his best known. Though primarily a painter of landscapes and genre scenes, he also excelled in figure painting, sketches, and marine subjects. He published the book *Sketches of Paris Manners* in 1820.

CHALON-SUR-SAONE, shā-lōn'sūr-sōn' (ancient CABBILLONUM), city, France, in the Department of Saône-et-Loire, located on the right bank of the Saône River at the terminus of the Canal du Centre (opened 1793), about 70 miles north of Lyon. It has a branch (*Petite-Creusot*) of the Schneider works of the Le Creusot engineering company, and is a transport and commercial center for wines, grains, and livestock. Its manufacturing establishments include machine shops, copper and iron foundries, glass and tile works, and shipyards for river boats. Printing, sugar refining, brewing, and tanning are carried on.

Under its ancient name Cabillonum it was a town of the Aedui, and Julius Caesar maintained grain magazines here. In the 6th century A.D. it was the capital of Burgundy. In 813 a church council was summoned here by Charlemagne. When King Edward I of England, returning from a crusade with 1,000 men-at-arms, attended a tournament at Chalon in 1273, a dispute arose, and the English attacked the French, killing a great number, and leaving the tilting ground strewn with the dead. This event is known as "the little war of Chalon."

The town suffered considerably from the civil wars of the 15th and 16th centuries, and from the invasion of the allies during the Napoleonic Wars in 1814. The bishopric was suppressed by

the French Revolution. Its ancient cathedral of St. Vincent, built mainly during the 12th and 15th centuries, was badly damaged in World War II, when Chalon lay on the border between occupied and unoccupied France. Pop. (1946) 32,683.

CHALONER, chāl'ō-nēr, Sir Thomas, English diplomat and poet: b. London, England, 1521; d. Clerkenwell, London, Oct. 14, 1565. After studying at both Oxford and Cambridge universities, he accompanied (1540) the British ambassador to the court of Emperor Charles V and thence to Algiers. He served as member of Parliament at various times from 1545 to 1555, and accompanied Edward Seymour, afterward duke of Somerset (known as the Protector), to Scotland, where he fought at the Battle of Pinkie (1547). Several embassies took him to Scotland and France, and under Queen Elizabeth he was sent (1558) on a mission to Emperor Ferdinand at Courtrai (Kortrijk) and to Philip II at Brussels. From 1561 to 1564 he was ambassador to Spain. Chaloner translated into English a homily of St. John Chrysostom (1544) and the *Praise of Folly* (1549) by Desiderius Erasmus. In addition he wrote verses and elegies in Latin, among them an elegy on Lady Jane Grey, first published in 1579. Hans Holbein, the Younger painted his portrait. His son, Sir Thomas Chaloner, the Younger (1561-1615), was a noted naturalist.

CHALONS-SUR-MARNE, shā-lōn'-sūr-mār-n', commune, France, capital of the Department of the Marne, about 25 miles southeast of Reims, located in the chalk country of the Champagne Pouilleuse, on the right bank of the Marne River and on its lateral canal. Once famed for its worsted cloth (*chalouns*), it is today a commercial center for champagne and cereals, and manufactures beer, barrels, leather goods, barbed wire, and wallpaper. Châlons-sur-Marne is also an important road, railway and canal center for northern France.

Its ancient name was Catalaunum, and it was fortified by the Romans. In 451 A.D. at the decisive BATTLE OF CHÂLONS, the Huns under Attila were defeated by Aëtius and Theodoric I on the nearby plains (Catalaunian Plain).

From the 10th century Châlons formed a kind of independent state governed by its bishops until 1360, when it was united to the French kingdom. The English laid siege to the city in 1430 and 1434. In 1870 the town was occupied by the Germans after Marshal MacMahon's withdrawal. The Germans held it again briefly in World War I (August to September 1914) before yielding it in Battle of the Marne. Its 13th-17th century cathedral and other historic edifices were damaged in World War II. Pop. (1946) 31,120.

CHALOSSE, shā-lōs', a historic region of Gascony, France. Situated along the Pyrenees in the country's southwest, it is traversed by the Adour River and now forms part of the Landes Department, of which it is the only productive farming district. The principal towns are Aire and Saint-Sever.

CHALOTAIS, La, French 18th century magistrate. See LA CHALOTAIS.

CHALUKYA, chā'lōok-yā, a Hindu dynasty

of the Deccan in central India, which flourished first from about 500 to 753 A.D. In approximately 550 it established its capital at Vatapi (now Badami) in what is today the Bijapur District of Bombay. The kingdom may be said to have been properly founded by Pulakesin I (550–566); it was expanded by his sons Kirtivarman I and Mangalesa, and reached its zenith under his grandson Pulakesin II (608 or 609–642), who about 611 started the dynasty of the Eastern Chalukyas (611–c.1078) by placing his brother Kubja Vishnuvardhana on the throne of Pishtapura and Vengi.

Pulakesin II sent an embassy to Khosrau II of Persia in 625 and enthroned one of his sons as head of a branch dynasty in south Gujarat. Both branches were continually at war with their neighbors, and in 642 Pulakesin was defeated by the Pallava king Mahendravarman I whose capital was Kanchi (now called Kanchipuram). Pulakesin's son and successor Vikramaditya I (655–680) re-established the Chalukya domain, which achieved new triumphs under the latter's great-grandson Vikramaditya II (733–746) who defeated the Pallavas. But his son, Kirtivarman II was overthrown by Dantidurga (Dantivarman II) of the Rashtrakuta dynasty about 753 or 754.

Another branch, the (Western) Chalukyas of Kalyani (or Kalyana) is generally considered to have been founded by Tailapa or Taila II in 973 and to have lasted until 1200 (or 1190).

The Chalukya-Chola Dynasty was founded by Rajendra III, king of Vengi (Eastern Chalukya dynasty), who took the vacant throne of Kanchi in 1074, assumed the name Kulottunga Chola I, and put a viceroy in Vengi. It lasted until 1267, when the empire was taken by the Hoysalas.

The Chalukyans developed an interesting style of architecture combining Indo-Aryan and Dravidian elements. It is represented by the star-shaped richly decorated shrine of Mysore with several cells combined into one temple. They also built many cave temples with cliff reliefs and stone sculptures.

CHALUMEAU, shà-lü-mō' (Fr., from the Latin *calamellus*, small reed or reed pipe), a reed instrument widely used in the 17th century, but now obsolete. It was the ancestor of the modern clarinet and was related to the shawm, forerunner of the oboe. The term chalumeau is used also to designate the lowest register of the clarinet and as a direction to play a passage an octave lower.

CHALYBEATE WATERS, kà-līb'ē-āt, those waters containing iron in sufficient quantity to warrant their usage in anemia. In the past such waters—also referred to as **IRON WATERS**—were considered of great value. Many thousands of patients suffering from anemia and debility traveled long distances to Saratoga, New York; Harrogate, Tunbridge Wells, and Bath, in England; and various European spas such as Kissingen, Germany, and St. Moritz, Switzerland, in the hope of securing relief through the medicinal properties of the waters. It is now known that iron is much better administered by the way of pills containing the salt in definite quantity, or by intravenous injections of iron preparations. As a consequence, the popularity of chalybeate waters has considerably diminished.

HAROLD WELLINGTON JONES, M.D.

CHALYBES, kal'i-bēz, an ancient people renowned for their metallurgical skill. Their exact habitat is still disputed, but they probably lived in northern Asia Minor along the Black Sea. Xenophon refers to them as living in the mountains between Armenia and Mesopotamia, and he seems—like several other authors of antiquity—to confuse them with the Chaldaeans. The Greeks considered the Chalybes the first workers of iron, and credited them with the invention of steel, which they called *chalybs* or *chalybos*.

CHALYBITE. See **SIDERITE**.

CHAM, chām, a Moslem tribe of Indochina now found mainly in the southern part of Annam and in Cambodia. Their physical features and language suggest an Indonesian origin, but traces of Indian and to a lesser extent Chinese influences are evident. Nominally Moslem, their religion is a mixture of Islam, Hinduism, Buddhism, and animism. The earliest Cham inscriptions date from the 4th century A.D. Around 1000 A.D. the Cham were in possession of a vast territory along the coastline of Annam, but they were later overwhelmed by their Annamese neighbors, and partly absorbed by them. They live on agriculture, and have developed a remarkable system of irrigation for their rice fields.

CHAM, kām (pseudonym of COUNT AMÉDÉE DE NOÉ), French caricaturist: b. Paris, France, Jan. 26, 1819; d. there, Sept. 5, 1879. Best known for his crayon contributions to *Charivari*, illustrated French periodical, he dealt lightly with familiar everyday things and events.

CHAMA, kâ'mâ, a genus of bivalve mollusks, the typical one of the family Chamidae. The shell has foliaceous valves, the upper one being the smaller, and one valve is attached to another body by the left umbo; the hinge tooth of the free valve is received between two teeth of the other. The chamas are found less than 50 fathoms deep in tropical seas, especially among coral reefs. As many as 50 recent species are known, and 40 fossil, the latter from the Cretaceous onward. The still existing *Chama gigas* sometimes weighs 300 pounds, and may measure four feet across. The byssus by which it adheres to the rock is so tough that a hatchet is required to cut it through. One valve is sometimes used in churches as a baptismal font.

CHAMACOCOS, chā-mā-kō'kōs, a nomadic Indian people of central South America, living in the Chaco of Paraguay, principally in the Olimpo Department of the country's northwest, west of the Paraguay River.

CHAMAEROPS, kâ-mē'rōps, a genus of palms of but one or possibly two species popularly called fan palms. This palm is extremely variable in appearance and size; the trunks may be clustered and are then about three feet high. Single trunks, however, reach 20–30 feet high. The leaves are fan shaped, and the leaf stalks usually bear spines. *Chamaerops humilis* is the only palm native to Europe, where it occurs in the Mediterranean region. It is cultivated in California and in the Gulf coast region of the United States, and in greenhouses elsewhere. A fiber obtained from the leaves is used for padding mattresses.

CHAMALHARI, peak in the Himalayas. See **CHOMO LHARI**.

CHAMAN, chǎ'mūn, town, Pakistan, located in northeastern Baluchistan on the Afghanistan border near Chaman Pass and about 60 miles northwest of Quetta. It is an important border station and rail terminus. Cantonment pop. (1941) 6,650.

CHAMARS, chá-märs' (from Sanskrit *car-makāra*, leather worker), a low caste of India having considerably more than 10,000,000 members who live chiefly in the country's north and in Nepal. Their traditional trade is tanning and related leather work, but they perform also other menial labors for high-caste Hindus; a great many have become farmers.

CHAMARTIN DE LA ROSA, chā-mār-tēn' dā là rró'sā, suburb of Madrid, Spain, until 1947 a separate municipality (1940 pop., 64,485), located to the north of the capital. Chamartin has important mechanical industries; there is a Jesuit college and the palace of the dukes of Osuna. Among its sections are Tehuán de las Victorias, Ciudad Lineal, and Castillejos.

CHAMAVI, kâ-mā'vī, a Germanic tribe that occupied roughly the present Netherlands about 100 A.D. The Chamavi fought together with the Cherusci against the Romans, but were later absorbed by the Franks, although they retained their own law code, the *Lex Chamavorum*.

CHAMBA, chūm'bā, district and town, India, in northern Himachal Pradesh. The district is bordered on the north and west by Kashmir, and on the south by the Punjab of India; it is a mountainous region in the Himalaya foothills; area, 3,127 square miles; pop. (1941) 168,908. Its capital, Chamba, is a trade center, pop. (1941) 6,597.

CHAMBAL or **CHUMBUL**, chūm'bāl, un-navigable river, chief tributary of the Jumna, in west-central India; it is subject to sudden floods during the rainy season. Length, about 550 miles.

CHAMBELLAN, chām'bēl-lān, **Rene Paul**, American sculptor: b. West Hoboken, N. J., Sept. 15, 1893. After studying at the École Julian in Paris and with Solon Hannibal Borglum, he served with the United States Army in France during World War I, and worked with Borglum on the Pershing Stadium at Vincennes, France, before returning to the United States where he taught sculpture at New York University. His artistic work has been devoted, in the main, to decorating buildings with sculptured groups, figures, and plaques—notably at Yale University, Rockefeller Center, several state offices in New York and Buffalo, the Chicago Tribune Building, the Crowell-Collier Building in New York, and the New York World's Fair. In addition, he has designed several medals, such as the Iwo Jima commemorative.

CHAMBER, a term having various technical meanings. The chamber of a cannon is that part of the bore which receives the powder with which it is charged.

The chamber of a mine is the place where the

charge of powder is lodged that is to be used for exploding the mine.

In several languages, the term chamber is employed to designate a branch of government whose members assemble in a common hall.

A chamber of commerce is a board or association formed to promote the interests of trade and merchandising. See also **CHAMBERS OF COMMERCE**.

CHAMBER MUSIC (Ger. *Kammermusik*, Ital. *música da cámara*), instrumental music of an intimate character, written for performance by two or more players, in which no part is a solo with accompaniment, but all parts are of equal importance. The term implies that chamber music is suitable for performance in a room or in a medium-sized auditorium. Actually, the name became current in the early 17th century, when it was used to distinguish secular from sacred music.

Origins of Chamber Music.—In its beginnings, chamber music flourished as a result of the patronage of the aristocracy; where such noble support was uncertain, the cultivation of this art was less general. In Italy, for example, Arcangelo Corelli (1653–1713) lived and worked under the protection of Cardinal Pietro Ottoboni; he was, therefore, a leader in the group of chamber music composers which included Antonio Vivaldi. Henry Purcell, in England, worked more or less individually, and his chamber music works are isolated examples of great genius.

George Frederick Handel and Johann Sebastian Bach owed the form of their chamber music works to the 17th century Italians, although Handel, without aristocratic patronage, produced comparatively little chamber music, other than his violin sonatas. Bach, however, during his Köthen period (1717–1723), when he was Kapellmeister and director of Kammermusik to Prince Leopold of Anhalt, produced a whole catalogue of sonatas and suites for small instrumental combinations.

Chamber Music Development.—Starting with Joseph Haydn, the development of chamber music was carried on most effectively by German and Austrian composers, from the date (c.1755) of Haydn's first chamber music work, to the death of Johannes Brahms (1897). Haydn enjoyed the patronage of Prince Miklós József Esterházy, and his genius flourished under the conditions in which he worked. His contribution was not only the establishment of the sonata form as the framework for all instrumental chamber music, but also the development of the string quartet and other works for chamber music combinations as balanced conversation between the instruments.

Mozart continued Haydn's patterns and gave to the instruments still more independence, and to his works a deeper emotional significance. Ludwig van Beethoven, presaging the advent of the romantic school (Franz Schubert, Robert Schumann, and others), added further breadth and independence to the string quartet; many scholars feel that chamber music has not advanced very far since his time, although Brahms, considered by many to be more classicist than romanticist, surely added many imposing works to the repertoire.

Almost every composer has written works for various chamber music combinations; and, with certain of the romanticists, the introduction of the piano, and the vogue of the piano quintet (string quartet and piano), seem to indicate that

the composers of these works (Robert Schumann, César Auguste Franck, and others), were writing more for the concert hall than for private performances in the home or the studio.

Modern Chamber Music Composers.—More recent composers, likewise, have found the chamber music forms an effective medium. The French impressionists, Claude Debussy and Maurice Ravel, composed works which are truly chamber music, in spirit, even though their effectiveness is based on atmospheric harmony and timbre, rather than on design and form. Still more recently, many contemporary composers have reverted, somewhat, from the exploitation of the more colorful tonal textures of works such as Arnold Schönberg's *Verklärte Nacht*, and have returned to the more objective types of absolute, as opposed to program (descriptive), music. This is particularly true of the neoclassic composers, who turn to the contrapuntal devices of the past, and adapt them to more contemporary idioms.

Wind and String Instrument Combinations.—Although string instruments have always been the bulwark of chamber music combinations, wind instruments (especially wood winds and French horns) have often been added to the ensemble combinations (Mozart's quintet for clarinet and string quartet; Brahms' horn trio for violin, horn, and piano; and others). In addition, numerous chamber music works have been composed for combinations of wind instruments only; and, occasionally, for brass instruments.

W., *Cyclopedic Survey of Chamber Music* (London 1929-30); Kilburn, N., *Chamber Music and its Masters in the Past and in the Present* (London 1932); Ulrich, H., *Chamber Music: The Growth and Practice of an Intimate Art* (New York 1948); Rowen, R. H., *Early Chamber Music* (New York 1949).

JOHN TASKER HOWARD.

CHAMBER OF COMMERCE OF THE UNITED STATES, a federation of commercial organizations and trade associations, formed in 1912 on the recommendation of President William Howard Taft, to help Congress "keep in closer touch with commercial affairs." It has its headquarters in Washington, D.C.

The National Chamber, as it is widely called, is composed of more than 3,100 affiliated organizations—local, state, and regional chambers of commerce, and trade and industrial associations. There are more than 21,000 business members, including firms, corporations, and individuals. Its underlying membership, that is the membership of its affiliated organizations, is more than 1,600,000.

The chamber carries on its work by (1) studying national economic problems and defining current questions; (2) ascertaining the views of business, and determining what business feels is the best solution to a national problem; and (3) voicing and explaining the views of business to the public and to the government.

The policies of the chamber represent the majority opinions of its members. A proposed policy must be "national in character, timely in importance, and general in application to business and industry." A chamber policy may be adopted in one of the three following ways: (1) by vote of delegates at an annual meeting; (2) by referendum of affiliated organizations; and (3) in an emergency, by the board of directors. Unless reaffirmed, a chamber policy automatically expires three years after adoption.

The chamber maintains division offices in New York City, N. Y.; Atlanta, Ga.; Dallas, Texas; Minneapolis, Minn.; Chicago, Ill.; and San Francisco, Calif. The work of the organization is governed by a board of directors, made up of 50 members elected by the affiliated organizations. Staff activities are carried out through 13 specialized departments, three member-organization service departments, and four coordinating and operating departments.

The specialized departments deal with national issues and organization policies, and are: agriculture, construction and civil development, domestic distribution, finance, foreign commerce, foreign policy, insurance, manufacture, natural resources, transportation and communication, economic research, education, and labor relations. The service departments are: chamber of commerce service department, state chamber of commerce department, and trade association department. The coordinating and operating departments are: information department, legislative department, membership sales department, and *Nation's Business* magazine department.

The National Chamber publishes *Nation's Business*, a general business monthly, circulation about 800,000; *Washington Report*, a weekly newspaper for distribution to members, libraries, public officials, and the press; *Legislative Daily*, a summary of congressional action; *Legislative Outlook*, published every two weeks when Congress is in session; and departmental newsletters and numerous research studies and reports.

CHAMBER OF DEPUTIES, the lower of the two legislative chambers or second house of the national Parliament in France, Italy, and other countries. The first French Chamber of Deputies was established under Louis XVIII in 1814. By enactment introduced in 1830, any citizen of 30 years and upward who paid direct contributions to the extent of 500 francs, might be elected as a deputy. Originally the chamber was elected for five years: in 1824 it became septennial and in 1830 it was again limited to five years. Under the Constitution of 1875 of the Third Republic, the Chamber of Deputies was elected for four years by manhood suffrage. The manner of election of deputies has been modified several times. The *scrutin de liste*, under which each elector votes for as many deputies as the entire department has to elect, was introduced in 1871. In 1876 it was replaced by the *scrutin d'arrondissement*, under which each department is divided into a number of *arrondissements*, each elector voting for one deputy only. In 1885 there was a return to the *scrutin de liste*; in 1889 the uninominal vote was reintroduced.

On Oct. 13, 1946 the constitution prepared by the National Constitutional Assembly was adopted by popular vote and the Fourth Republic came into being on Dec. 24, 1946. The name of the lower house was changed from Chamber of Deputies to National Assembly. This body is elected by equal, direct, and secret universal suffrage for a five-year term unless earlier dissolved. Dissolution is possible only after two cabinet crises within 18 months after the National Assembly has been in existence for 18 months. The National Assembly exercises more power than did the Chamber of Deputies under the Third Republic. The upper house, no longer called the Senate but the Council of the Republic, has only consultative powers.

The present electoral law adopted in 1951, replacing that of 1946, compromises between proportional representation under the *scrutin de liste* and the single-member district or *scrutin d'arrondissement*, with the object of discriminating in favor of the center parties and against both the Communists at the extreme left and the Gaullists at the right. In the election of June 1951, the center parties sustained their majority in the National Assembly, which has a total membership of 627 deputies.

In Italy, under the constitution of 1948, the Chamber of Deputies is composed of 574 members elected for five years unless the chamber is dissolved. In both France and Italy, deputies must be 25 years old, and receive compensation for their services.

QUINCY WRIGHT.

CHAMBERLAIN, chām'bēr-līn, (Arthur) Neville, British statesman: b. Birmingham, England, March 18, 1869; d. Heckfield, Hampshire, Nov. 9, 1940. The second son of Joseph Chamberlain and half brother of Sir (Joseph) Austen Chamberlain, he was educated at Rugby and Mason College, Birmingham. From 1890-1897 he resided in the Bahamas, managing a plantation. In 1911 Chamberlain became a member of the Birmingham City Council and 1915-1916 he was lord mayor of Birmingham. He entered Parliament in 1918 and after 1922 held various cabinet posts, including chancellor of the exchequer from 1931 until May 28, 1937, when he succeeded Stanley Baldwin as prime minister.

Almost immediately his ministry faced difficulties created by the Spanish Civil War and the Sino-Japanese conflict. To protect Britain's interests in the Mediterranean, he negotiated a treaty with Italy ratifying the Ethiopian conquest on condition that Italy withdraw from Spain. In 1938 he signed the Munich Pact with Italy, France, and Germany, under which certain areas of Czechoslovakia were surrendered to Germany in the hope of preserving what he called "peace in our time." Six months later Adolf Hitler had broken the agreement, and Chamberlain tried to change his policy, saying that England would not allow any further German aggression. He failed, however, to form an alliance with Russia, the one country which might have been able to help Britain block German designs on Poland.

Chamberlain was forced to lead his country into war on Sept. 3, 1939, after the Russo-German agreement of the preceding month had made it possible for Germany to invade Poland. For the next eight months he remained at the head of the government, but growing criticism of his war policies culminated in his resignation on May 10, 1940, after the German invasion of France. Succeeded by Winston (later Sir Winston) Churchill as prime minister, he became lord president of the council. He remained in the cabinet until October 3, when he resigned because of ill health.

CHAMBERLAIN, Austen. See CHAMBERLAIN, SIR JOSEPH AUSTEN.

CHAMBERLAIN, Charles Joseph, American botanist: b. Sullivan, Ohio, Feb. 23, 1863; d. Chicago, Ill., Feb. 5, 1943. He graduated from Oberlin College in 1888, then taught in Ohio and Minnesota until 1893, when he entered the University of Chicago, graduating as doctor of philosophy in 1897. He remained at this institution

until his retirement in 1929, serving as professor of plant morphology and cytology after 1915.

His interest in morphology and cycads took him on several expeditions to the tropics of southern Mexico, and trips to Cuba, New Zealand, Australia, and Africa. Among his published works are *The Morphology of Spermatophytes* (1901) and *The Morphology of Angiosperms* (1903), both with John M. Coulter (q.v.); *Elements of Plant Science* (1930); and *Gymnosperms, Structure and Evolution* (1935).

CHAMBERLAIN, Daniel Henry, American politician: b. West Brookfield, Mass., June 23, 1835; d. Charlottesville, Va., April 13, 1907. He graduated from Yale College in 1862, attending Harvard Law School the following year. After serving as an officer during the Civil War, he settled in South Carolina, and was state attorney general in 1868-1872. He was elected governor of South Carolina in 1874 and again in 1876. However, his reelection was contested by Wade Hampton, the Democratic candidate. President Rutherford B. Hayes conferred with both men in Washington, and the United States troops which had been in South Carolina supporting Chamberlain were withdrawn, whereupon Chamberlain relinquished his claim to the election. He moved to New York and opened law offices there. After traveling in Europe and Egypt he settled in Virginia in 1906.

CHAMBERLAIN, George Earle, American politician: b. near Natchez, Miss., Jan. 1, 1854; d. Washington, D.C., July 9, 1928. He graduated from Washington and Lee University in 1876, and started law practice in Oregon. There he became a state legislator, state attorney general, and governor (1902-1909). From 1909 to 1921 he was United States senator from Oregon, serving as chairman of the Military Affairs Committee after 1913 and aiding legislation dealing with the draft, food control, and war financing. He bitterly criticized the War Department for delays in the early months of World War I. Defeated for re-election in 1920, he was appointed a member of the United States Shipping Board.

CHAMBERLAIN, Houston Stewart, Anglo-German author: b. Southsea, Hampshire, England, Sept. 9, 1855; d. Bayreuth, Germany, Jan. 9, 1927. Educated in France and England, he went to Germany in 1870 to study German culture and came to believe that European civilization owed most to German contributions. In 1908 he married Eva, daughter of Richard Wagner, as his second wife. His book *The Foundations of the Nineteenth Century* (1911), won acclaim in Germany for its scholarly advocacy of German superiority, but was condemned elsewhere for its nationalist prejudices. Among his other works are *Richard Wagner* (1897); and *The Wagnerian Drama* (1915).

CHAMBERLAIN, Jacob, American missionary: b. Sharon, Conn., April 13, 1835; d. Madanapalle, Madras, India, March 2, 1908. He graduated from Western Reserve College in 1856 and the Dutch Reformed Theological Seminary at New Brunswick, N. J., in 1859, then studied medicine at the College of Physicians and Surgeons, New York City. In 1860 he went to India, establishing hospitals at Madanapalle in 1868 and at

Palamanair 1872. He translated the Reformed Church liturgy into Telugu Madras (1873), and also *Hymns for Public and Social Worship* (1884). He wrote *The Bible Tested* (1878; 7th ed., 1885); *Native Churches and Foreign Missionary Societies* (1879); *Winding up a Horse; or Christian Giving* (1879); *Break Cocoanuts Over the Wheels; or All Pull for Christ* (1885); *The Kingdom in India: Whose?* (1907); *The Cobra's Den and Other Stories of Missionary Work among the Telegus of India* (1900).

CHAMBERLAIN, John Loomis, American army officer: b. Livonia, N. Y., Jan. 20, 1858; d. Washington, D.C., Nov. 5, 1948. He was graduated at the United States Military Academy in 1880. For years he was an officer of the line. He was graduated from the Army Service School, the Artillery School at Fort Monroe and the Army War College, and for four years (1884-1888) he was an instructor at the Military Academy, West Point. In the winter of 1890-1891, while a junior officer in the service, he took an active part in the campaign against the Sioux Indians. In 1891-1893 he was chief ordnance officer of the Missouri department and in 1895-1896 served as instructor in military science and tactics at the Peckskill Military Academy. In 1897-1898 he was appointed military attaché at Vienna, but resigned this post on the outbreak of hostilities with Spain. Throughout the war he served as a major of United States Volunteers with the Seventh Army Corps. In 1900 he became a major in the inspector-general's department through a competitive examination, open to all captains of the line. He investigated the Pacific transport service in 1901, the result being a complete reorganization of the personnel. He spent five years service in the Philippines and in the course of his duties he also visited China and Japan. In 1913 his investigation of the aviation section of the Signal Corps resulted in changes of policy and a reorganization of the service. In February 1917 he was appointed inspector general, with the rank of brigadier general, and on Oct. 6, 1917 major general. He made a tour of inspection of the American Expeditionary Force in France in 1918; of all war department activities in Great Britain and Europe in 1920; and in Europe, the Middle East and Africa in 1921. He retired Nov. 6, 1921.

CHAMBERLAIN, Joseph, English statesman: b. London, July 8, 1836; d. Birmingham, July 2, 1914. He was for a time at University College School, London, and in 1854 he entered into partnership with his cousin, Joseph Nettlefold, as a screw manufacturer in Birmingham—a business in which his father was also interested. He retired from active business life in 1874 after having amassed a handsome fortune. He was by this time coming to the front as the "rising hope" of the advanced Radicals. As a member of the Birmingham School Board, and its chairman from 1874 to 1876, he took up an attitude of uncompromising hostility to the denominational school system. In 1869, he was elected a member of the Birmingham Town Council. His tenure of the mayoralty (1874-1876) was notable for sweeping reforms; new municipal buildings were built, the gas and water undertakings were municipalized and a great city improvement scheme was successfully carried out. After an unsuccessful parliamentary contest at Sheffield

in 1874, he was in 1876 returned unopposed for Birmingham. He rapidly made his mark in Parliament; he infused new life into the Radical organization, and on the return of the Liberals to office in 1880 entered the Cabinet as president of the Board of Trade. To Mr. Chamberlain's exertions was due the passing of an important bankruptcy act, and his attempt to amend the merchant shipping acts, though unsuccessful, formed the basis of later legislation. His influence meantime was rising in the country; he stood out as an opponent of "coercion" in Ireland and favored a large measure of self-government, and in the election of 1885 he preached the doctrine of "ransom" and the "restitution" of property with a frankness that alarmed moderate Liberals, and enunciated an "unauthorized program" which included free education, small holdings, and a graduated system of taxation. After that election and the subsequent defeat of the Salisbury ministry and when the tenure of the Liberal government in office depended on the Irish vote and a Home Rule measure became imminent, he accepted the presidency of the Local Government Board, but resigned on March 15, 1886 on account of hostility to Mr. Gladstone's Home Rule Bill of that year. With the other "dissentient Liberals" he voted against that measure and assisted materially in the defeat of the Liberals at the polls at the ensuing general election. For a time it seemed as if the breach in the Liberal ranks might be healed, but after a Round Table conference in 1887 it grew wider and Mr. Chamberlain became the object of intense dislike on the part of the Home Rule Party. He held no office in the Unionist administration from 1886 to 1892, but his influence was felt in legislation, and he succeeded in getting some radical measures passed, such as free education. As a member of the commission to settle the fisheries dispute with Canada, he visited Washington in 1887 and succeeded in negotiating the Chamberlain-Bayard Treaty, which however was refused ratification by the United States Senate. Another result of his visit was that he married in 1888, as his third wife, Mary, daughter of William C. Endicott, Secretary of War in President Cleveland's first administration.

On the elevation of Lord Hartington (Victor Christian William Cavendish) to the House of Lords as the 9th duke of Devonshire in 1891, Mr. Chamberlain succeeded to the leadership of the Liberal Unionists in the House of Commons. During the passage of Mr. Gladstone's second Home Rule Bill (1893) through the House of Commons, Mr. Chamberlain was the life and soul of the opposition, his discussion of the various amendments being marked by a masterly debating power and keen analytical skill. On the return of the Unionists to power in 1895 he was appointed Secretary for the Colonies. His tenure of that office may be said to have been the turning point in the relations of the colonies with the mother country; his sympathetic understanding of colonial aspirations was soon apparent, and his talents as a business man and skill in administration found a fruitful field. When the "Jameson Raid" occurred in the Transvaal, he at once repudiated all connection with it on the part of the British authorities, and he subsequently denied in the most distinct manner having had any personal foreknowledge or suspicion of what was about to take place. The country was sharply divided on his conduct of the negotiations preceding the outbreak of the

war with the South African Republic in 1899, but his influence in the country was a main cause in the Unionist triumph in the election in 1900. On the conclusion of hostilities he visited South Africa and personally initiated the measures adopted to repair the ravages of war. His influence was manifest in the provisions of the Workmen's Compensation Act of 1897, and he carried through the Australian Commonwealth Bill in 1900.

In 1903 he launched another "unauthorized program," which aimed at the reversal of the traditional free trade fiscal policy of Great Britain and at the setting up of preferential tariffs within the Empire, and he resigned his place in the Cabinet the better to pursue this missionary enterprise. He found support from the majority of the Unionist party; but a powerful minority, including such distinguished men as the duke of Devonshire, George Joachim Goschen, and Earl St. Aldwyn, stood for the old policy; Arthur James Balfour, on whom devolved the duty of keeping his party together, gave to "tariff reform" but a dubious and hesitating support; the Unionist party was rent in twain; and at the general election of 1906—at which Chamberlain's policy was only one among other issues—the Unionist government suffered a disastrous defeat. Chamberlain from 1903 had been conducting a strenuous campaign on behalf of "tariff reform" that had severely taxed his strength, and his last years were spent as an invalid; but from time to time he continued to inspire his followers with messages in the press.

He was the first purely business man, untaught in any of the universities, to rise to a commanding place in British public life, and he profoundly affected the style of debating in the House of Commons. In his talents as an administrator, in his capacity for getting through business, he was almost unrivaled. As a debater he was cool and resourceful, never so dangerous as when fighting in a disadvantageous position. He had, as Lord Morley said, a "genius for friendship," as demonstrated by the fidelity of his West Birmingham constituents over a period of nearly 40 years.

H., *Mr. Chamberlain, His Life and Public Career*, 2 vols. (London 1904); Mackintosh, A., *Joseph Chamberlain; an Honest Biography* (London 1906); Garvin, J. L., *Life of Joseph Chamberlain*, 3 vols. (London 1932-1934).

CHAMBERLAIN, Sir Joseph Austen, British statesman: b. Birmingham, Oct. 16, 1863; d. London, March 16, 1937. Eldest son of Joseph Chamberlain and half brother of Arthur Neville Chamberlain (q.v.), he was educated at Rugby and at Trinity College, Cambridge, and later studied in Berlin and Paris. Elected to Parliament in 1892 he entered on a distinguished career in which he filled numerous government posts, the most important of which were the chancellorship of the exchequer (1903-1906 and 1919-1921) and the foreign secretaryship (1924-1929) in the Cabinet of Stanley Baldwin (q.v.). His direction of post-World War I financial policies contributed substantially to paying off Britain's indebtedness and strengthening foreign credits. Chamberlain's conduct of foreign affairs significantly led to the signing of the Locarno Pact (see LOCARNO, PACT OF) and he was accorded recognition in 1925 when he shared the Nobel

Peace Prize with Charles Gates Dawes (q.v.). He also received considerable credit for Germany's entrance into the League of Nations, whose council and assembly meetings he frequently attended. In 1921 Chamberlain was Conservative leader of the House of Commons and advocated the creation of the Irish Free State. He retired as first lord of the admiralty and from active political life in October 1931. Chamberlain's published works include *Peace in Our Time* (1928), *Down the Years* (1935), *Politics from Inside* (1936), and *Seen in Passing* (1937).

Consult Petric, Charles, *Life and Letters of Sir Austen Chamberlain* (Toronto 1939-1940).

CHAMBERLAIN, Joshua Lawrence, American soldier and educator: b. Brewer, Me., Sept. 8, 1828; d. Feb. 24, 1914; graduated Bowdoin College 1852 and Bangor Theological Seminary 1855; professor of rhetoric and oratory, Bowdoin, 1856, and in 1861 professor of modern languages of Europe. On Aug. 8, 1862, he entered the army as lieutenant-colonel of volunteers and served through the Civil War in the Army of the Potomac in every campaign, and was several times wounded, twice severely. He received the Congressional Medal of Honor for his remarkable conduct in the defense of Little Round Top, Gettysburg, July 2, 1863, and was advanced to the command of a brigade. On June 18, 1864, he was promoted brigadier-general on the field by General Grant for distinguished gallantry in leading a desperate charge, and early the following spring he received a special promotion as brevet major-general. In the campaign of 1865 he commanded two brigades of the 1st Division, 5th Corps. In the order disbanding that army he was retained in the service and was offered a colonelcy in the regular army, but the condition of his wounds induced him to decline the service, and in January 1866 he returned to Maine.

In the autumn of that year he was elected governor of Maine, and served in that office for four terms. In 1871 he was chosen president of Bowdoin College, and continued in that position for 12 years, his administration being marked by a broadening of the course and a large increase in the resources of the college. During this time he was elected major-general of Maine, to command the militia of the state. In 1879, when for a time there was no active or legal state government, he was called to the capital "to preserve the peace and institutions of the state." This he accomplished without the use or show of military force. In 1883 he retired from the presidency of Bowdoin and settled in New York to practise law. In 1884 he went to Florida and engaged in the work of railroad building and public improvements on the West Coast. He published *Maine, Her Place in History* (1877); *Ethics and Politics of the Spanish War* (1898); *De Monts and Acadia* (1904); *Ruling Powers in History* (1905); *The Passing of the Armies* (1915). He also edited *Universities and Their Sons* (1898).

CHAMBERLAIN, Mellen, American lawyer, librarian, and historian: b. Pembroke, N. H., June 4, 1821; d. Chelsea, Mass., June 25, 1900. He was graduated at Dartmouth College in 1844 and at the Harvard Law School in 1848. In 1849 he was admitted to the bar, opened a law office in Boston, and made his residence in

Chelsea, where he served the town in many public capacities the remainder of his life. In 1858 and 1859 he was a member of the Massachusetts General Court and the senate in 1863-1864. He was associate justice of the municipal court of Boston 1866-1870, and chief justice 1870-1878. In August 1878 he was chosen librarian of the Boston Public Library, serving until ill health compelled his retirement in 1890. During his administration the new library building was begun and the cornerstone laid. Throughout his life he was a close student and investigator of American history.

Besides important chapters in Justin Winsor's *Narrative and Critical History of America*, vol. 6 (1888), he wrote *John Adams, the Statesman of the American Revolution, with Other Essays and Addresses, Historical and Literary* (1890), edited by Lindsay Swift.

CHAMBERLAIN, Montague, Canadian American naturalist: b. Saint John, New Brunswick, April 5, 1844; d. 1924. He was educated privately, both his parents being teachers. Though engaged in mercantile pursuits, he devoted much time to the study of natural history and came to be well known as an ornithological writer. In 1889 he became assistant secretary of the Lawrence Scientific School of Harvard University, and from 1893-1900, secretary.

A member of several scientific bodies, his chief publications are *Canadian Birds* (1870); *Birds of New Brunswick* (1882); *Mammals of New Brunswick* (1884); *Systematic Table of Canadian Birds* (1887); *Birds of Greenland* (1892); *Some Canadian Birds* (1895); *The Church Army* (1897); *Maliseet Vocabulary* (1899); and *The Penobscot Indians* (1899).

CHAMBERLAIN, Nathan Henry, American clergyman: b. Bourne, Mass., Dec. 25 or 28, 1828-1830?; d. there, April 1, 1901. He graduated at Harvard, 1853, and studied theology at the divinity school there, and at Heidelberg, Germany, eventually becoming a Unitarian minister. He was pastor at Canton, Mass., 1857-1859, and at Baltimore, Md., 1860-1863. He then took orders in the Episcopal Church and became rector at Birmingham, Conn., 1864-1867; subsequently serving in New York, Wisconsin, and Massachusetts. He then retired to devote himself to literary pursuits. His books are *Autobiography of a New England Farm House* (1864); *The Sphinx in Aubrey Parish* (1889); *What's the Matter? or Our Tariff and its Taxes* (1890); *Samuel Sewall and the World He Lived In* (1897), an admirable study of colonial life in New England; *Sir Charles Napier; An Itinerary of Cape Cod*.

CHAMBERLAIN, Neville. See CHAMBERLAIN, ARTHUR NEVILLE.

CHAMBERLAIN, Samuel Selwyn, American journalist: b. Walworth, N. Y., Sept. 25, 1851; d. San Francisco, Calif., Jan. 25, 1916. He was graduated from New York University in 1871 and entered the journalistic field with the *New York Herald*. He went abroad with James Gordon Bennett of the *Herald* and was for a time editor of the Paris edition of that journal. In 1879 he became editor of the *World* but left to take charge of the *Evening Telegram* in 1881. He founded *Le Matin* of Paris in 1884 and

edited it for two years and then returned to the United States.

In 1889 William Randolph Hearst engaged him as editor of the San Francisco *Examiner* and he remained on the Pacific coast until 1895, when he came to New York as editor of the *Evening Journal*. In 1900 he became managing editor of the Philadelphia *North American*, which soon resumed its old place among the successful publications of that city. In a year or two Mr. Chamberlain returned to the Hearst service, and until his death acted as general staff officer. He went to the Chicago *Examiner*, was recalled to the New York *American*, and for several years, until the spring of 1915, had been the Hearst representative in London. His last work was editor of the Boston *American*. He was recognized as an exceptionally able newspaper man; his forte was a news touch of charming delicacy; he had unerring news perception and understood and carried out feature ideas that were distinct.

CHAMBERLAIN, chām'bēr-līn, city, South Dakota, seat of Brule County; altitude 1,360 feet; on the Missouri River about 10 miles north of its confluence with the White River; on the Chicago, Milwaukee, St. Paul and Pacific Railroad; about 65 miles west of Mitchell. It is a stock-raising and dairying center. Nearby is a large deposit of manganese. The area was explored by the French, and Lewis and Clark were here in 1804.

Immediately north of the city are the Crow Creek and Lower Brule Indian reservations. The city was incorporated in 1881. Pop. (1940) 1,626; (1950) 1,912.

CHAMBERLAIN (ME. from OF. *Chamberlenc*; OHG. *chamarling* fr. G. *kammer* fr. L. *camera*, chamber), court officer, originally employed, as the name indicates, to take charge either of the private apartments of a prince, or of a treasury. The golden key, which is worn by the chamberlains of the European courts on two small golden buttons (as well as the buttons themselves, when the key is omitted), indicates also the origin of the office. At present the employment of chamberlains (when their office is not merely nominal) is to attend on the persons of the princes and their consorts. There is generally a chief or high chamberlain. This officer in England is called Lord Great Chamberlain of England. His office is one of great antiquity and honor, being ranked as the sixth great office under the English crown. It is entirely distinct from that of Lord Chamberlain of the Household (see below).

To the Lord Great Chamberlain belong lodging and livery at the king's court; and there are certain fees due to him from each archbishop and bishop when they perform their homage to the king; and from all peers at their creation on doing their homage. On the coronation day, this officer is to bring the king his shirt, coif, and wearing apparel, and after the king is dressed, he claims his bed and all the furniture of his chamber for his fees; he also carries at the coronation the coif, gloves and linen to be used by the king on that occasion; also the sword and scabbard, the gold to be offered by the king, and the robes royal and crown; dresses and undresses the king on that; waits on him before and after dinner, etc. This

officer has also the care of providing all things in the House of Lords during session; the government of the palace of Westminster; and the disposal of the sword of state, when carried before the king, to any lord of his choice. The office of lord great chamberlain of England is hereditary, descending from a grant of Henry I (r. 1100–1135) through the family of De Vere, earls of Oxford. The holders in the reigns of George VI and Elizabeth II were the earls of Ancaster and the marquesses of Cholmondeley, who take it in turn. At the beginning of Elizabeth II's reign (1952) it was held by George Horatio Charles Cholmondeley, the 5th marquess. During a queen's reign some of his duties, especially at the coronation, are shared by a mistress of the robes.

The lord chamberlain of the household is an officer who has the oversight and direction of all the officers belonging to the king's or queen's chambers, except the precinct of the bedchamber. To his department belong the two drama censors, called "examiners of plays."

The chamberlain of London receives and keeps the city money which is stored in the chamber of London; he also presides over the affairs of masters and apprentices, and admits duly qualified persons to the freedom of the city. His tenure of office is for a year, like that of the lord mayor, but he usually is re-elected.

At all monarchical courts there are almost as many different chamberlains as there are kinds of chambers; the English chamberlains here cited, and their duties, may be taken as typical.

CHAMBERLIN, chām'bēr-lin, **Thomas Crowder**, American geologist: b. Mattoon, Ill., Sept. 25, 1843; d. Chicago, Ill., Nov. 15, 1928. After graduating from Beloit College in 1866 and pursuing his studies at the University of Michigan, he became a professor first at the State Normal School, Whitewater, Wis., and from 1873 to 1882 at Beloit, where he began his great work on the studies of glacial deposits with relation to climatic conditions in past geological ages. This took him to Switzerland in 1878. After publishing *The Geology of Wisconsin* in four volumes (1873–1882), he was appointed chief of the Division of Glacial Geology in the United States Geological Survey. From 1887 to 1892 he was president of the University of Wisconsin. From 1892 to 1919, when he retired, he was head of the department of geology in the University of Chicago and director of the university's Walker Museum. Chamberlin founded the *Journal of Geology* in 1893 and was editor in chief until 1922. Soon afterward he began to publish papers on the spiral-nebula or planetesimal hypothesis of the earth's origin. In 1916 he published *The Origin of the Earth*, one of many important studies, and his final work, *The Two Solar Families*, in 1928.

CHAMBERS, Edward Thomas Davies, Canadian journalist: b. Saffron Walden, Essex, England, June 26, 1852; d. Quebec, Canada, Oct. 5, 1931. Emigrating to Canada in 1870, he taught for a short time and then entered journalism, becoming editor in chief of the *Quebec Daily Chronicle* in 1897. In his later years he served in the Department of Colonization and Fisheries at Quebec. Among his publications were *The Port of Quebec: Its Facilities and Prospects* (1890); *Quebec, Ancient and Modern* (1892); *Chambers' Guide to Quebec* (1895); *The Onana-*

niche and its Canadian Environment (1896); *The Anglers' Guide to Eastern Canada* (1898); and *The Quebec Tercentenary Commemorative History* (1909).

CHAMBERS, Ephraim, English miscellaneous writer and encyclopedist: b. Kendal, Westmoreland, England, 1680; d. Islington, May 15, 1740. Upon leaving school he was apprenticed to a maker of globes and mathematical instruments in London. Through that association he acquired such a taste for the study of science and became so proficient in it that he not only conceived the idea of compiling his famous *Cyclopaedia*, or *an Universal Dictionary of Arts and Sciences*, but also wrote some of the articles. The first edition was published in 1728 in two volumes. Subsequent editions appeared in 1738, 1739, 1741, 1746. A French translation of the *Cyclopaedia* was the basis of the *Encyclopédie* compiled by Denis Diderot and Jean Le Rond d'Alembert in 35 volumes (1751–1780). Revised and enlarged editions were prepared by George L. Scott (1753) and in four volumes by Abraham Rees (1781–1786), who later used it as a basis for his *Cyclopaedia* (1819). Thus the *Cyclopaedia* was the source whence other famous works sprang.

CHAMBERS, Ernest John, Canadian writer and public servant: b. Penkridge, Staffordshire, England, April 16, 1862; d. Ottawa, Ontario, Canada, May 11, 1925. He settled in Canada at an early age, received his high school education in Montreal, entered journalism with the *Montreal Star*, and joined the militia. When the Indians of northwest Canada rebelled in 1865, he acted as a war correspondent. In 1893 he returned to Ottawa to edit the *Canada Military Gazette*. This brought him into official circles, and he served as gentleman usher of the black rod in the Canadian Parliament (1904–1925). Contact with parliamentarians, in turn, resulted in his editorship of the *Canadian Parliamentary Guide* (1908–1925). He maintained his interest in the militia and, when World War I began, he was appointed censor at Military Headquarters, Ottawa, and in 1915 chief press censor for Canada. Despite his numerous activities he wrote the histories of nine regiments. Two of his more important books are *The Royal North West Mounted Police* (1906) and *The Unexploited West* (1914), based on his travels throughout the Far West.

CHAMBERS, George, English marine painter: b. Whitby, Yorkshire, England, 1803; d. London, Oct. 28, 1840. His early life was spent at sea where his sketches showed so much promise that he was allowed to abandon his apprenticeship to study painting. While supporting himself as a house painter, his work attracted the attention of Thomas Horner, who engaged him to paint a panorama of London for the exhibition building in Regent's Park. Employing water colors as well as oils, he exhibited at the Royal Academy. Two of his marine pictures are in the Greenwich Naval Hospital: the *Bombardment of Algiers in 1816* and the *Capture of Portobello*.

CHAMBERS, Robert, Scottish publisher and author: b. Peebles, Scotland, July 10, 1802; d. St. Andrews, March 17, 1871. Largely self-educated and in poor circumstances, he moved with his family to Edinburgh in 1813. His interest in that city led to his writing *Traditions of Edin-*

burgh in two volumes (1823; new ed. 1868). He opened a bookseller's shop in 1816 and, prospering, began to publish his books on Scottish history and his collections of rhymes and ballads of Scotland. With his brother William (q.v.) he began publication of *Chambers's Journal*, whose success led to the founding of the publishing firm of W. & R. Chambers (1832). With Robert Carruthers he wrote a *Cyclopaedia of English Literature* in two volumes (1844). His greatest work was *Vestiges of the Natural History of Creation*, published anonymously, to avoid attack, in 1844; its true authorship was disclosed in 1884. Charles Darwin considered it a valuable preparation for his own work. After a visit to the United States in 1860, Chambers moved to London to collect material for his *Book of Days* (q.v.) in two volumes (1862-1864).

CHAMBERS, Robert William, American artist and author: b. Brooklyn, N. Y., May 26, 1865; d. New York, N. Y., Dec. 16, 1933. Beginning his career as an artist and illustrator, he wrote his first book on his life as a student in Paris, *In the Quarter* (1894), and thereafter made writing his lifework. A play, *The Witch of Ellengowan*, written for Ada Rehan, was performed in New York in 1897. His early novels were French historical romances, *The Red Republic* (1895) and *Lorraine* (1898). Then his knowledge of upper New York State, Sir William Johnson, and the Indians, produced his finest work, novels of the American Revolution, *Cardigan* (1901); *The Maid-at-Arms* (1902); and *The Reckoning* (1905).

An excellent naturalist and collector of butterflies, he lived during the summer months at Broadalbin, Fulton County, N. Y., where he wrote nature stories for children: *Outdoorland* (1902); *Orchard-Land* (1903); and others. He was known as a collector of Japanese and Chinese antiques. His most successful novels financially were the society novels. Among these were *The Fighting Chance* (1906); *The Danger Mark* (1909); and *The Common Law* (1913). A novel, *Iole*, a satire on the "new art" of his day, published in 1905, was made into a musical comedy in 1913. Later he returned to historical novels in *The Hidden Children* (1914); *Little Red Foot* (1921); and *The Sun Hawk* (1927). His short stories and serialized novels were published in magazines until his death.

CHAMBERS, Sir William, English architect: b. Stockholm, Sweden, 1726; d. London, England, March 8, 1796. Brought to England by his British parents in 1728, he lived at Ripon, Yorkshire, where he was educated. Visiting China as supercargo to the Swedish East India Company, he made many drawings of Chinese buildings and costumes, which were engraved and published in 1757. He traveled in Italy and France to study architecture and soon after his return in 1755 was appointed drawing master to the prince of Wales, afterward George III. His first important assignment was the villa for Lord Bessborough at Roehampton, in classical style. He designed the royal gardens at Kew in Chinese style, including the pagoda. One of the first members of the Royal Academy (established 1768), he exhibited many architectural drawings and designed many town houses in London, Dublin, and Edinburgh, as well as country mansions. He rebuilt Somerset House in London (1775),

one of his most successful works. His *Treatise of Civil Architecture* (1759) was a popular manual and had several editions.

CHAMBERS, William, Scottish bookseller and printer: b. Peebles, Scotland, April 16, 1800; d. Edinburgh, May 20, 1883. The elder brother of Robert Chambers (q.v.), he was the business expert of the firm of W. & R. Chambers. With Robert, he published *Chambers's Encyclopaedia* first issued in 520 weekly parts between 1859 and 1868. They employed Andrew Findlater as editor and adapted some material, by agreement, from the famous German *Konversations-Lexikon* published by F. A. Brockhaus. As a writer himself, he published *Things as They are in America* (1854); histories of Italy, France, and Scotland; books on animals, on slavery, and on various tours which he took. He is remembered for his gifts to Edinburgh in reconstructing parts of the old town, donating Chambers Institution, and restoring St. Giles' Church while he was lord provost.

CHAMBERS, in law, the office or private rooms of a judge. For the convenience of the parties to a lawsuit, a judge may hear matters and transact other business "at chambers" or "in chambers" when a hearing in open court is not required. Examples of chambers business are the signing of judgments and the taxing of costs. Such business may be conducted either in term (that is, when the court is in session) or in vacation. Chambers are not necessarily a specific room or location, for the term denotes any place where a judge's work out of court is performed.

CHAMBERS OF COMMERCE, organizations composed of business and professional men in practically every principal city in the Western World. In the United States, Canada, and Great Britain, the chamber of commerce is a voluntary organization, independent of the government, and organized for the improvement both of business in its community and of the community itself. In Continental Europe and in several South American countries, the chamber of commerce has some official connection with the government, is supported in whole or in part by the government, and has certain duties assigned to it, such as compiling business and trade statistics, licensing new businesses, drafting laws relating to business and industry, and acting in an advisory capacity on proposed legislation.

In the United States, the chamber of commerce is a democratic organization voicing its members' majority opinion, and by its bylaws prohibiting its officers and directors from perpetuating themselves in office. A chamber's program varies according to size, location, resources, and needs of its community, but in general includes: (1) betterment projects designed to improve such things as schools, housing, traffic control, parking facilities, playgrounds, parks, hospitals, and airport; (2) promotional projects designed to increase trade and to attract new industries and more tourists; (3) educational projects designed to build greater public interest in current economic and social issues and to create a better understanding of the American system and operation of free enterprise.

Besides local chambers of commerce in the United States, there are also regional chambers and state chambers. And to express the views of businessmen on national issues, the chambers of commerce collaborate through a national federation of commercial organizations.

and trade associations, the Chamber of Commerce of the United States, founded in 1912. The national chamber maintains headquarters at 1615 H Street, N.W., Washington, D.C.; and divisional offices in New York, N. Y.; Atlanta, Ga.; Chicago, Ill.; Minneapolis, Minn.; Dallas, Texas; and San Francisco, Calif. Affiliation with the national chamber is voluntary, not automatic. The younger businessmen of the country, between the ages of 21 and 35, have their own organization, the United States Junior Chamber of Commerce, founded in 1920, with headquarters at 21st and Main streets, Tulsa, Okla., and with chapters in many towns and cities. The junior chamber stresses "training in citizenship and in chamber of commerce work to promote civic, industrial, and educational activities."

Historically, the roots of the chamber of commerce go back to the merchants' guilds of the 12th century, when these were formed to protect and promote their members' interests. The first organization to be known as "chamber of commerce" was established by the civic council of Marseille, France, in 1599. Later chambers of commerce were organized in other French cities and proved so successful in dealing with commercial and trade problems, that in 1700 Louis XIV ordered every trading center in France to form a similar organization. In 1789, however, Louis XVI, believing that chambers of commerce and trade guilds had become overly powerful, ordered them to be suppressed. A few years later Napoleon, in an effort to stimulate trade, ordered their re-establishment. Meanwhile, chambers of commerce had been organized in England, Ireland, and Scotland. In 1768 a chamber of commerce was formed on the island of Jersey in the English Channel. In 1783 chambers were created in Dublin and Glasgow; in 1785, in Edinburgh and Leeds; and in 1881, in London.

The oldest chamber of commerce in the United States is the Chamber of Commerce of New York, 65 Liberty Street, New York, N. Y. It was founded by a group of 20 merchants in 1768, was granted a charter by King George III in 1770, and has been in continuous operation ever since. It is said to be the first commercial organization in the world created entirely independent of the government. The early chambers of commerce in the United States, like those in England and in Europe, were concerned solely with trade and commerce. During the latter part of the 19th century, the number of chambers in the United States increased rapidly, and the organizations embarked upon general community development and promotion work. The Cleveland, Ohio, Chamber of Commerce, organized in 1848, generally is recognized as perhaps the first modern chamber of commerce in the United States, in that it was formed as both a commercial development and as an organization to improve the community.

The Chamber of Commerce of the United States sponsors six summer institutes to train executives for chamber of commerce work, and to upgrade those already in the work. These institutes are held at Northwestern University, Evanston, Ill.; Yale University, New Haven, Conn.; Adolphus Hotel, Dallas, Texas; Montana State University, Missoula, Mont.; University of North Carolina, Chapel Hill, N. C.; and Stanford University, Palo Alto, Calif. It publishes *Nation's Business* (monthly); *Legislative Outlook* (biweekly); *Washington Report* (weekly); *Legislative Daily*; and *American Economic Security* (8 issues yearly).

The International Chamber of Commerce, organized in 1920, has its headquarters in Paris. The office of the United States Council of the international chamber is at 103 Park Avenue, New York, N. Y.

ART BROWN,

Chamber of Commerce of the United States of America.

CHAMBERSBURG, borough, Pennsylvania, and seat of Franklin County; altitude 620 feet, on the Conococheague and Falling creeks, and served by the Pennsylvania and Western Maryland railroads, an airport, two federal and three state highways, 50 miles west-southwest of Harrisburg. Blue limestone, freestone, and marble abound in the vicinity and there is a large trade in farm products. Industries include railway repair and reclamation shops and manufactures of men's and women's clothing, hosiery, tomato and apple products, steam presses, power transmission machinery, and paper towels. Caledonia Park, a 260-acre state forest, is 10 miles to the east.

Chambersburg is the seat of Wilson College (1869) and of Penn Hall Junior College (1927), both for girls. The beautiful Wilson College campus was landscaped by the essayist Donald G. Mitchell (Ik Marvel).

History.—Chambersburg was first settled in 1730 by Benjamin Chambers, an immigrant from Ireland, who built a stone fort here after James Braddock's defeat in 1755. The settlement, for many years called Falling Spring, was incorporated in 1803. President James Buchanan was born nearby and the cabin where he was born was moved to the city in 1925. John Brown planned his raid on Harper's Ferry while he lived in Chambersburg in 1859. Here Gen. Robert E. Lee gathered his forces for the Battle of Gettysburg in 1863. Next year, in Gen. Jubal A. Early's raid into Pennsylvania, Gen. John McCausland entered Chambersburg with Confederate cavalry on July 30, 1864, and demanded a tribute of \$100,000 gold. When the money was not paid, the place was set on fire. The borough owns and operates the waterworks and an electric light and power plant. Its government is by chief burgess and council. Pop. (1950) 17,212.

CHAMBERTIN, shān-bēr-tān', a superior red burgundy wine, named after the place where it is produced, in the Department of Côte d'Or, France.

CHAMBERY, shān-bā-rē, city, France, capital of the Department of Savoy, 54 miles east of Lyon, at the junction of two small rivers, near the Isère. It is an archbishop's see, and contains a 14th to 15th century cathedral, six hospitals, a castle, a college, a museum, and a public library. In its vicinity are excellent baths, much frequented in summer.

It has several distilleries and manufactures machinery, clothing, flour, leather goods, and vermouths. The town is a communications center on the Paris-Lyon-Mediterranean Railroad.

History.—Chambery was founded in the 10th century. During the Middle Ages it was under feudal lords until 1232, when it was ceded to Thomas, 1st count of Savoy, who built the castle where the rulers of the house of Savoy resided until the government was removed to Turin in 1560. The town was surrendered to the French Revolutionists in 1792 and became the capital of the Department of Mont Blanc. It was ceded in 1815 to Savoy, which retroceded it to France in 1860. It suffered some damage in World War II. Pop. (1946) 29,975.

CHAMBEZI, chām-bé'zī, a river of Africa, in Northern Rhodesia, rising in the highlands south of Lake Tanganyika. Its tributaries are large and form a considerable stream which flows

about 300 miles southwest to Lake Bangweulu, thence to emerge as the Luapula River.

CHAMBLISS, Charles Edward, American entomologist: b. Petersburg, Va., Aug. 20, 1871. Graduating from the University of Tennessee in 1892, he was instructor in zoology and entomology there from 1894 to 1900 and in the same period was entomologist of the Tennessee Agricultural Experiment Station. From 1900 to 1901 he was state entomologist of Tennessee, when he became associate professor of zoology and entomology at Clemson College, entomologist of the South Carolina Experiment Station during 1901-1907, and state entomologist there from 1907 to 1908. From 1908 to 1930 he was agronomist in charge of rice investigations for the United States Department of Agriculture, traveling in Puerto Rico, the Dominican Republic, and in Cuba. From 1930 to 1941 he was the department's official in charge of rice technology and botany. After 1941 he was a collaborator in the department.

CHAMBLY CANAL. See CANADIAN CANALS.

CHAMBONNIERES, shān-bō-nyār', **Jacques Champion de**, French composer, harpsichordist, and organist: b. 1602; d. Paris, France, about 1672. The son and grandson of two famous organists, Antoine and Jacques Champion, he became the founder of the French harpsichord school. In 1643, Anne of Austria, wife of Louis XIII, named him first harpsichordist of the court, where he continued into the reign of Louis XIV. Chambonnières instructed Louis Couperin, uncle of the more renowned François Couperin (both of whom wrote for the harpsichord), and others among his numerous following. He published *Pièces de clavecin* in two volumes (1670; new ed. 1926).

CHAMBORD, shān-bōr', **COMTE DE** and **DUC DE BORDEAUX** (**HENRI CHARLES FERDINAND MARIE DIEUDONNÉ D'ARTOIS**), Bourbon claimant to the French throne: b. Paris, France, Sept. 29, 1820; d. Frohsdorf, Austria, Aug. 24, 1883. Born after the assassination of his father, Prince Charles Ferdinand de Bourbon, duc de Berry, he became the last claimant of the elder branch of the French Bourbon dynasty when his grandfather, King Charles X, abdicated in his favor after the revolution of 1830. His uncle, Louis, duc d'Angoulême, the eldest son of the king, renounced his rights at the same time. The Legitimists named the baby Henri V of France.

With his title unrecognized by the people, who had enthroned Louis Philippe of the house of Orléans, he was compelled to leave the country, and lived successively in England, Germany, Italy, and Austria, keeping a sort of court and occasionally issuing manifestoes. In 1846 he married Archduchess Maria Theresa, eldest daughter of the duke of Modena, and in 1851 inherited the domain of Frohsdorf, near Vienna, where he subsequently lived and died without issue. While abstaining from violent attempts to seize the crown, he omitted no opportunity of urging his claims, especially after the defeat of Napoleon III at the Battle of Sedan in 1870; but his belief in the divine right of the Bourbons and his failure to recognize accomplished facts and modern tendencies, destroyed all chance of his succession.

CHAMBORD, village, Quebec, Canada, in Lake St. John County, on the southern shore of Lake St. John. Industries include dairying and lumbering. Pop. (1951) 1,029.

CHAMBORD, a castle, park, and village in central France about nine miles northeast of Blois, Department of Loir-et-Cher. The splendid Renaissance castle, or château, on the Cosson River, a branch of the Loire, stands in the middle of a park, enclosed by walls over 20 miles in circumference. Begun in 1519 by Francesco Primaticcio in the reign of Francis I, it has a central square building (the keep) with a tower at each corner and a grand interior staircase surmounted by a lantern tower. The huge main façade is flanked by four round towers and comprises a great rectangle of buildings entirely empty save for the apartments on the first floor of the keep, which were those of Louis XIV, under whom the castle was completed. A number of French architects, including Pierre Nepveu, were responsible for it.

After the reign of Henri II the court sometimes stayed at Chambord, and Louis XIV used it for notable receptions. King Stanislas I Leszczyński of Poland lived there from 1725 to 1733; in 1745 it was given by Louis XV to Marshal Hermann Maurice de Saxe, who died there in 1750; Napoleon I gave it to Marshal Louis Alexandre Berthier. In 1821 a company of Legitimists bought it for the duke of Bordeaux, who had just been born, and when in exile he took his title, comte de Chambord, from it. Bequeathed to the ducal family of Parma in 1883, it was bought by the state in 1932 and is open to the public.

CHAMBRE ARDENTE, shān'br ar-dant' (fiery chamber), an apartment hung with black and lighted with tapers, in which the corpse of a person of distinction is deposited before the funeral ceremonies. The name was formerly given in France to an apartment, similarly draped and lighted, in which sentence of death, frequently by burning, was pronounced on heinous offenders.

In a historical sense the term is more especially given to an extraordinary tribunal which, from 1535 to 1680 in France, directed persecutions against heretics and acted as a sort of inquisition. The members of the tribunal, who were named by the pope, ferreted out heretics, tried them, pronounced sentence, and saw it executed. A *chambre ardente* was employed by Louis XIV to investigate the numerous cases of poisoning which, after the proceedings against Marquise Marie de Brinvilliers in 1676, were brought before the public. Many persons of the highest rank, among others Duke Francis of Luxembourg and Princess Louise of Savoy, were examined before this court between 1679 and 1680. The last exercise of its powers was at the celebrated trial of Catherine La Voisin for sorcery in 1680.

CHAMBRE INTROUVABLE, ān'trōō-vā-bl (the chamber whose like is not to be found), the term applied to the French Chamber of Deputies which met after the second return of Louis XVIII (from October 1815 to September 1816) and which by its fantastic loyalty threatened to plunge France again into anarchy and commotion. Its dissolution met with universal rejoicing. The electoral law of 1817 prevented the return of a similar chamber.

CHAMELEON, ká-mě'lě-ün, a southern circumpolar constellation, bounded by Octans, Apus, Musca, Carina, Volans, and Mensa. It was introduced by Edmund Halley in 1679. It is inconspicuous and contains 16 naked-eye stars, of which only four attain the fourth magnitude.

CHAMELEON, ká-mě'lě-ün or ká-mě'l'yün, any of about 90 species of lizards of the family Chamaeleontidae, found throughout Africa (except the Sahara), in Spain, Arabia, and the Near East eastward into India. They are most closely related to the Agamidae, an entirely Old World family of lizards related to the American Iguanidae.

Unlike most lizards, the chameleons are not swift and scampering creatures which pursue their prey, but rather are imbued with a lethargy seen elsewhere only among the mammalian sloths. All but one are arboreal and creep slowly through the branches or, more frequently, sit quietly upon a twig, maintaining a firm hold with their parrot-like feet. These feet are characteristic of the Chamaeleontidae and are not matched elsewhere among the reptiles, for on the hand two digits are directed outward, three inward, and on the foot three digits are directed outward and two inward, thus forming a grasping organ.

Since the slowness of the chameleons prevents pursuit of insects (their normal prey), chameleons are dependent on the remarkable agility of their tongue. The tongue is exceedingly long, in some species longer than the body, and terminates in a blunt and sticky tip which serves precisely the function of flypaper. Normally, the tongue is contracted and tightly telescoped upon its spike-like internal skeleton and lodged in the throat; but when an insect is spotted within range, the chameleon shoots forth its tongue with great rapidity, catching its prey on the sticky tip, and then, more slowly, retracts the tongue to bring the food within the jaws.

The eyes of chameleons are scarcely less remarkable, but can be approached among some of the Agamidae. The upper and lower lids are nearly completely fused, leaving a pinhole aperture for vision. The eye may be rotated forward and back, upward and down, and each eye can be rotated independently of the other. Chameleons almost continuously roll the eyes in this disconnected fashion, which gives them a somewhat disquieting appearance.

Considering the number of truly unique features possessed by the chameleon, it is perhaps unfortunate that they are famed chiefly for their ability to change color (metachrosis), an ability matched among some other lizards and exceeded among many fishes. This change, which usually ranges from blackish through greenish to pale pinkish, is a response primarily to temperature (perhaps to light intensity as well), not to the color of the background, the lizard becoming darker at cooler temperatures. The old question of what a chameleon would do on plaid or polka dots can be resolved by determining the temperature of the plaid. The mechanism of color change involves expansion and contraction of the dark pigment corpuscles (melanophores) under the direct influence of the sympathetic nervous system.

The skull of chameleons is scarcely less remarkable than the tongue and the feet, principally in the arrangement of the bones of the snout; the premaxilla, which in other reptiles forms the anterior border of the upper jaw, has

been squeezed out of the jaw margin and has become involved chiefly in the architecture of the bony nostril; on the other hand, the nasal bone, in other reptiles forming most of the border of the nostril, in the chameleons does not meet the nostril at all. Most conspicuous of cranial features is the development in many of the species of bony horns, either on the snout or over the eyes, or both in combination, giving a vague, and quite spurious, resemblance to the ceratopsian dinosaurs.

The largest of the chameleons, the East African *Chamaeleo melleri*, reaches a length of slightly under two feet, from tip of snout to tip of tail, while some of the pigmy chameleons (genus *Brookesia*) are about four inches in length when fully grown. Some of the African chameleons bear the young alive, but most lay eggs. It has been established in at least one species that the female may store active sperm over a season to fertilize the next clutch of eggs, a phenomenon known in other reptiles. In some species there is questionable evidence that the female dies after depositing her clutch of eggs. The female of the common chameleon, *Chamaeleo chamaeleon*, buries her eggs in the ground after digging with her feet a hole of about six inches in depth; since a chameleon's feet are singularly ill-adapted for digging, the process may require several days.

The American anoles (genus *Anolis* and some related tropical American genera) are frequently called chameleons from their ability to change color from green to brown. These are the "chameleons" most often sold at pet shops and carnivals. One species, *A. carolinensis*, is native to the southeastern United States as well as to parts of the West Indies, while a second, *A. sagrei*, native to the West Indies, ranges into the southern tip of Florida. Over 100 related species are found in the West Indies, Central America, and South America.

The anoles are not closely related to the true chameleons, family Chamaeleontidae, but are members of the family Iguanidae, to which most of the diurnal North American lizards belong. The anoles do not have the peculiar feet, tongue, and skull seen in the true chameleons, and even their mechanism of color change is different, for there is no direct nervous control over the pigment corpuscles. Nevertheless, some of the tropical anoles have the skull prolonged into crests and helmetlike growths superficially like some of the true chameleons. The males have a fanlike fold of skin beneath the throat, distended during excitement by the action of the rodlike bones supporting the tongue; usually, this fan is brightly colored.

The anoles feed principally on insects, as do the chameleons, but the anoles capture their prey by pursuit. Anoles are egg-layers. The true chameleons are unable to regenerate the tail when that member is damaged; in all species of the genus *Chamaeleo* the tail is prehensile, but in the genus *Brookesia* it is not. In the anoles, on the other hand, the tail is never prehensile and is regenerated when damaged.

S. B. McDOWELL,

American Museum of Natural History.

CHAMELEON MINERAL, permanganate of potassium, so called because a solution of it changes from green, through a succession of colors, to a rich purple.

CHAMFORT, shān-fôr', Sébastien Roch Nicolas, French writer: b. near Clermont, Auvergne, France, April 6, 1741; d. Paris, April 13, 1794. An illegitimate child, he took the name of Chamfort for his writing, and lived, after he left the Collège des Grassins, where he had free schooling, mainly by his wit. Popular in Parisian society for his witty observations, he was patronized by the nobility and introduced at court. A tragedy played (1776) before King Louis XVI and Queen Marie Antoinette brought him a pension and he was made a member of the French Academy (1781).

A bohemian and a revolutionary at heart, Chamfort left the court (after 1786) because of an unfortunate love affair and went to live at the house of M. Joseph de Vaudreuil, where earlier he had come under the comte de Mirabeau's influence. When the French Revolution began, he was in the Jacobin party that stormed the Bastille and was secretary of the Jacobin Club. He originated a number of revolutionary epigrams, the most famous of which was the title for the Abbé Sieyès' pamphlet: "*Qu'est-ce que ce Tiers-Etat? Tout. Qu'a-t-il? Rien.*" (What is the Third Estate? Everything. What has it done? Nothing.)

Chamfort came into conflict with Jean Marat and Maximilien Robespierre after the downfall of the Girondins. Threatened with imprisonment, he tried to commit suicide and died later of his wounds. His best memorial is considered to be the collection of 1,800 bons mots published under the title *Chamfortiana*. His other works lack the sparkle of his conversation. His *Oeuvres complètes*, in five volumes, appeared in 1824-1825.

CHAMIER, shām'yēr, Frederick, English naval officer and novelist: b. London, England, 1796; d. Waltham Abbey, Essex, October 1870. The experiences for his novels were gained when he served in the British Navy from 1809 to 1833. He was a midshipman in the Mediterranean and saw active service with Sir Peter Parker on board the *Menelaus* during 1811-1814. After fights with French and Spanish ships, the *Menelaus* sailed to North America in 1814 to participate in the American War of 1812. Chamier then served in the Mediterranean and in the West Indies until 1826. He was retired in 1833 and was promoted captain in 1856.

On retirement Chamier turned to writing. Considered now as imitations of Capt. Frederick Marryat's, his novels were in his day very popular. Among them were *The Life of a Sailor* (1834); *Ben Brace* (1835); *The Arethusa* (1836); *Jack Adams* (1838); and *Tom Bowline* (1841). He also published *A Review of the French Revolution of 1848* (1849).

CHAMINADE, shā-mē-nād', Cécile Louise Stéphanie, French composer and pianist: b. Paris, France, Aug. 8, 1857; d. Monte Carlo, Monaco, April 18, 1944. A pupil of Benjamin L. P. Godard, she began composing when eight years old, and from the age of 18 appeared on the concert stage, frequently playing her own compositions on the piano. In 1908 she made a successful tour of the United States. Her best-known compositions include *Callirhoë*, a ballet symphony performed with great success at Marseille in 1888; *Les Amazones* for chorus and orchestra (1888); and a number of songs such as *Madrigal*, *Chanson Slave*, *Ritournelle*, *Fleur de*

Matin, and *Sans Amour*. She also wrote a concertstück for piano and orchestra, two piano trios, and many other works.

CHAMISSO, shā-mis'sō, Adelbert von, (originally LOUIS CHARLES ADÉLAÏDE DE CHAMISSO), German writer and naturalist: b. Châteaueu Boncourt, Champagne, France, Jan. 30, 1781; d. Berlin, Prussia, Aug. 21, 1838. At the outbreak of the French Revolution his family fled to Berlin, where Adelbert later served in the Prussian Army from 1798 to 1807. Returning to France, he was appointed professor in the lycée at Napoléonville, and for a time was one of the entourage of Mme. de Staël in Switzerland. He returned to Berlin to study natural science and was chosen a member of Otto von Kotzebue's scientific voyage around the world in the *Rurik*. Hoping to find the Northwest Passage, they made instead important discoveries in the North and South Pacific. Later he published *Remarks and Views on a Voyage of Discovery* (1819) and *Description of a Voyage Round the World* (1836). He presented the collections he made on the voyage to the museum of natural history in Berlin, where he was made superintendent of the botanic gardens and was given a doctorate.

His reputation as a naturalist was overshadowed by his fame acquired as a poet. In 1814 appeared his most famous and original prose tale, *Peter Schlemihls Wunderbare Geschichte*, which has been translated, among other languages, into English, and illustrated by George Cruikshank. See WONDERFUL HISTORY OF PETER SCHLEMIHL, THE.

His poetry is marked by vigor, correctness, and a thorough command of the German language, but is, in general, of a gloomy cast, although he is the author of some humorous pieces. Many of his ballads and songs, some set to music by Robert Schumann, are masterpieces of their kind. His collected works have been edited most recently by Hermann Tarbel, *Chamisso's Werke*, 3 vols. (Leipzig 1907).

Bibliography.—Hitzig, J. E., "Leben und Briefe von Adelbert von Chamisso," the title added to vols. 5-6 in *Adelbert von Chamisso's Gesammelte Werke* (Leipzig 1836-39; 6th ed., 1874); Fulda, Karl, *Chamisso und seine Zeit* (Leipzig 1881); Du Bois-Reymond, Emil, *Adelbert von Chamisso als Naturforscher*. (Leipzig 1889); Geiger, Ludwig, *Aus Chamisso's Frühzeit* (Berlin 1905); Kossmann, E. F., *Der deutsche Musenalmanach, 1832-1839* (The Hague 1909); Riegel, René, *Adelbert de Chamisso* . . . 2 vols. (Paris 1934); Schmid, Günther, *Chamisso als Naturforscher* (Leipzig 1942).

CHAMOIS, shām'ī or shā-mwä', a horned ruminant hoofed mammal, *Rupicapra rupicapra*, one of the goat-antelopes, native to the mountains of middle and southern Europe, and southwestern Asia, ranging from Spain to the Caucasus and Asia Minor. It is about the size of a goat but more graceful, and its neck is somewhat longer in comparison. The general color is brown; the head pale, almost yellow, with a dark stripe on each cheek; the hoofs black. The short black horns rise straight from the forehead, recurve backward at the tip, and may reach a foot in length.

The chamois may be found in summer in the highest alpine altitudes, close to and sometimes beyond the snow line. In winter it seeks the forests, where it is somewhat more protected from its enemies. In the Alps, where it has been much hunted and may now be taken only in

Chamois.

season, the chamois is rare and the herds are smaller than in the Carpathians and farther east. The breeding season is in March; the young are born in May and June.

The chamois is famous for its agility; it is timid, and, when feeding in flocks, one is always on the watch to announce danger by a peculiar whistling noise.

Chamois leather is valuable commercially for its softness and warmth (see LEATHER—*Chamois*). Ordinary "chamois leather," however, is prepared from sheepskin or goatskin. The flesh of the chamois is considered a table delicacy and the horns are used for ornamental purposes, especially for making souvenirs of Alpine tourist resorts.

KARL F. KOOPMAN.

CHAMOMILE, kām'ô-mīl, or **CAMOMILE**, a low perennial plant. *Anthemis nobilis*, belonging to the family Compositae and best known for its use as a home remedy. It has prostrate spreading branches, downy, aromatic, deeply cut (twice pinnate) leaves, and daisylike flowers. Chamomile is native to Europe, but in the United States has escaped from gardens and is widely distributed. Sometimes called Roman or English chamomile to distinguish it from the German chamomile (a related plant *Matricaria chamomilla* of similar appearance and use), *Anthemis nobilis* is grown commercially in Europe for the flower heads, normally yellow, which are dried and used in making a tea. The infusion is popular as a tonic, carminative, emmenagogue, and for many other uses; the flowers have been applied externally in poultices for such pains as rheumatism, earache, and toothache; the oil is used for cosmetics and perfumery, and an infusion of the flowers is used as a hair rinse.

CHAMOND, Saint. See SAINT CHAMOND.

CHAMONIX, shâ-mô-nê', or **CHAMOUNI**, sh-â-môô-nê' (derived from Fr. *champs munis* or Lat. *campus munitus*, fortified grounds), a valley of southeastern France, in the Department of Haute-Savoie, in the Savoy Alps, fully 3,500 feet above sea level. The valley is about 14 miles long and 1-2½ miles wide, lying southwest and northeast, its east side formed by Mont Blanc and other lofty mountains of the same range, and its west side by Mont Brévent and the Aiguilles Rouges. It is traversed in its

whole extent by the Arve River, which leaves the valley by a narrow gorge at the southwest end, through which also passes, high above the river, the highway to Sallanches and Geneva. At its north end the valley communicates with the Swiss canton Valais by two roads and a bridle path, the latter crossing the Col de Balme. The mountains on the west side of the valley, though attaining an altitude of 8,500 feet, are not covered with snow in summer; but those on the east side, in the range of Mont Blanc, being from 10,000 to 15,000 feet high, are always snow clad, except where the peaks are too perpendicular for snow to lie. From the snowy range proceed glaciers, some approaching near the cultivated fields. The three most important are the Glacier d'Argentière, the Glacier des Bossons, and the Mer de Glace, the last being one of the largest in the Alps. From its lower extremity the meltings of the glacier flow, in greater or less volume according to the season of the year, from under a naturally formed ice arch, the source of the Arveyron, a small stream flowing into the Arve. The lower slopes of the mountains are timber covered. The soil is not very fertile, but it is assiduously cultivated, and the inhabitants grow barley, oats, spelt, flax, and potatoes, raise cattle, and keep bees. During the winter, yarns, cloths, hats, and implements are made, and many articles carved from wood.

Of the numerous villages in the valley (pop. 5,883 in 1946), Chamonix-Mont-Blanc is chief. About 37 miles southeast of Geneva, at an altitude of 3,402 feet, it is a year-round tourist center. The ascent of Mont Blanc is usually made from it. Pop. (1946) 2,654.

CHAMORROS, chā-môr'rôs, natives of the Mariana Islands and Guam (qq.v.), in the western Pacific. One of the Micronesian divisions of the Pacific islanders, the Chamorros are distinguished by their lighter skin, fine physique, and independent spirit. Attacked by the Spaniards in the 17th century, they fought bravely and their numbers were greatly reduced. Since then under successive foreign governments they have intermarried so widely that no more than about 3,500 of unmixed blood remain. Guam is an unincorporated territory of the United States and the adjoining islands are administered by the United States as a trust territory.

CHAMP CLOS, shân klô' (French, meaning a closed-in field or area), formerly a place set apart for duels for those who wished to settle in that manner a lawsuit or a dispute of honor. This name was also given to any place where tournaments were held.

CHAMP DE MARS, shân dē mâr's', in Paris, France, an extensive area on the left bank of the Seine, between the river and the École Militaire. Constructed about 1770 as the military school's exercise field and parade ground, it subsequently has been the scene of various public festivals and great gatherings of people. It is about 1,100 yards long and about 550 yards wide, with four rows of trees on each side. Louis XVI and his family took part here, in 1790, in the great Fête de la Fédération, in which the king swore to defend the new constitution; in June 1794 it was the scene of the Fête de l'Être Suprême. In 1815 Napoleon selected the Champ de Mars for the scene of a general assembly of the French

people, at which he placed before the representatives of the nation the articles of a supplementary constitution, called *l'Acte additionnel*, intended to establish the legality of his throne. It has also been the site of international exhibitions since 1867.

CHAMP DE MARS, shān dě mǎrs (Lat. *Campus Martius*), and **CHAMP DE MAI**, shān dě-mǎ, the annual public assembly of the Franks. They were held originally in March and called from the place of meeting Champs de Mars. In the 8th century they were transferred by Pepin the Short, the father of Charlemagne, to the month of May, and called the Champs de Mai. At the Champs de Mai, all questions relating to public affairs, such as war, peace, and the enactment of laws, were decided by the majority. Those assemblies were held irregularly under the Merovingians, but became more frequent and systematic under the first Carolingians. Pepin called together only the nobility and the clergy, but Charlemagne ordered that every count should bring with him 13 men from his jurisdiction to represent the people in the General Assembly. The first descendants of Hugh Capet departed from this usage, but Philip IV, who reigned from 1285 to 1314, restored the third estate by calling together delegates from the cities.

CHAMPAC, chūm'pāk, or **CHAMPAK**, an East Indian tree (*Michelia champaca*), of the natural order Magnoliaceae. It has large axillary flowers of a deep yellow color, and very fragrant, which are much celebrated in Hindu poetry. The tree is sacred to Krishna, and the women of India adorn their hair with its blossoms. The bark is aromatic and bitter.

CHAMPAGNE, chām-pān' (Fr. shān-pān'y'), an ancient province, France, now a region, which before the Revolution formed one of the 12 great military governments of the kingdom. The name Champagne, formerly Champaigne, is derived from the vast plains which occupy the territory. Champagne was bounded on the north by the duchy of Luxembourg and the bishopric of Liège; on the east by Lorraine; on the south by Burgundy; and on the west by Orléanais, Île-de-France, and Picardy. It forms at present the departments of the Marne, Haute-Marne, Aube, Ardennes, and part of those of the Yonne, the Aisne, Seine-et-Marne, and Meuse. The land is fertile, and produces the celebrated wine called after its name. In the Middle Ages it was a countship of which Troyes was the capital, and was united with France when Louis Hutin, count of Champagne, succeeded to the throne of France under the title of Louis X in 1314.

CHAMPAGNE, a French wine made chiefly in the Department of the Marne, in the former province of Champagne. It is commonly divided into river and mountain wines (*vins de la rivière de Marne*, and *vins de la montagne de Reims*), the former being for the most part white, the latter red. Not all of these wines are sparkling or frothing, though by the name "champagne" is generally understood such wine as has been subjected to an imperfect fermentation, and contains a quantity of carbonic acid gas generated during the insensible fermentation in the bottle, this gas

being disengaged on removing the pressure by which it was detained in solution. The briskest wines are not always the best; they are, of course, the most defective in true vinous quality, and the small portion of alcohol which they contain immediately escapes from the froth as it rises on the surface, carrying with it the aroma, and leaving the liquor that remains in the glass nearly vapid. Hence the still or the creaming or slightly sparkling Champagne wines (*vins cré-mants* or *demi-mousseux*) are more highly prized by connoisseurs and bring greater prices than the full-frothing wines (*vins grand-mousseux*). By icing these wines before they are used the tendency to effervesce is in some degree repressed, but when they are kept cool this precaution is unnecessary. In general, it may be observed that the vineyards on the banks of the Marne supply the choicest wines, and that the quality degenerates in proportion as they recede from the river. Among the white wines of Champagne the first rank is generally assigned to those of Sillery, the produce of the vineyards of Damery, Cumières, Hautvilliers, and Dizy. Of the Reims Mountain wines those of Verzy, Verzenay, Mailly, Chigny, and Bouzy are most esteemed, but the Clos Saint Thierry furnishes perhaps the finest red champagne. The soil of the principal vineyards throughout Champagne is composed of a loose marl resting on chalk and sometimes mixed with flints. For the manufacture of the white Champagne wines black grapes are now generally used. In making the red wines the grapes are trodden before they are introduced into the vat. Champagne, when well made, and placed in cool cellars, will retain its good qualities from 10 to 20 years. See also WINE AND WINE MAKING.

CHAMPAGNY, shān-pā-nyé', Jean Baptiste Nompere de, Duc de CADORE, French naval officer and statesman: b. Roanne, Aug. 4, 1705; d. Paris, July 3, 1834. He entered the Royal Marines in 1774 and was a member of the States-General, National and Constituent assemblies. From 1791 until 1800 he remained in private life, being appointed by Napoleon in the latter year counselor of state. He was also employed by Napoleon as ambassador to Vienna (1801-1804), and as minister of the interior (1804-1807) and of foreign affairs (1807-1811), and he negotiated the marriage with Marie Louise. After Napoleon's downfall he transferred his allegiance to the Bourbons, under whom he was restored to the Chamber of Peers (1819).

CHAMPAIGN, shām-pān', city, Illinois, in Champaign County, at an altitude of 743 feet, 138 miles south of Chicago, on the Illinois Central, the New York Central, the Illinois Terminal, and the Wabash railroads. It adjoins Urbana on the west and the campus of the University of Illinois is in both cities. It is in an agricultural area and has a soybean processing plant, hybrid corn plant, railroad shop, planing mill, and manufactures of bleachers, road machinery, trailers, concrete culverts, forgings, industrial machinery, gloves, school supplies, athletic goods, and deep freeze units. It was settled about 1855 and called West Urbana, and incorporated as a city in 1860. Pop. (1950) 39,397.

CHAMPAIGNE, or **CHAMPAGNE**, shān-pān'y', Philippe de, Belgian painter of the

Flemish school: b. Brussels, May 26, 1602; d. Paris, Aug. 12, 1674. He went to Paris at the age of 19, and worked on the decorations of the Luxembourg under Jean B. J. Duchesne. He was later appointed by Richelieu to adorn his palace and to paint murals for the dome of the Sorbonne. He was one of the first members and finally rector of the Academy of Painting. His coloring is excellent and his portraits possess great merit. His best pictures are at Vincennes and at Paris; among them are a portrait of himself, a portrait of Richelieu, *La Cène*, and *Les Religieuses*, all in the Louvre.

CHAMPE, chāmp, John, American soldier: b. Loudon County, Va., 1752; d. Virginia, c.1807. He was selected by request of Gen. George Washington to go to New York as a deserter and spy, and if possible to seize and bring off Benedict Arnold in time to save the life of John André. Sergeant Major Champe undertook the enterprise with courage, passed the American lines with difficulty, was hotly pursued by his comrades as a deserter, reached New York, underwent an examination before Sir Henry Clinton, and by him was consigned to General Arnold, who gave him in the British Army his former rank. He discovered the custom of Arnold to walk in his garden at a late hour every night, formed a plan with a comrade to seize and gag him there, and to take him between them as a drunken companion to a boat on the Hudson, whence arrangements were made for his transportation to the American headquarters. On the appointed night Arnold failed to appear in the garden, and Champe, after waiting for him until near morning, returned with deep chagrin to his position in the British Army. It proved that Arnold had the day before changed his quarters, preparatory to the embarkation of his troops for Virginia. There was nothing left for Champe but to embrace the first opportunity to escape to the American Army, which he did soon after landing in Virginia, and joined the troops under Gen. Nathanael Greene. Washington discharged him from further service, lest, falling into the hands of the enemy, he should be immediately put to death.

CHAMPEAUX, shān-pō', Guillaume de, French philosopher: b. Champeaux, c.1070; d. 1121. He was so called from the place of his birth. He studied at Paris under Anselme de Laon and Roscelin, and afterward himself opened a school there in which he had numerous pupils. The schools opened by de Laon and Champeaux are regarded by some as the origin of the University of Paris. Among the pupils of Champeaux were Robert de Bethune, one of the distinguished prelates of the age, and still more famous, Pierre Abélard. Jealous of the younger man's acumen he retired from his school in 1113 to the abbey of St. Victor. A few months later he was made bishop of Châlons-sur-Marne. He defended the doctrine of realism against the nominalism of Abélard; but it is only in the works of Abélard that any record of their contention remains. Champeaux has left a treatise on the origin of the soul, *De Origine Animae*, in which he examines the question wherein children dying without baptism are justly damned, which he concludes by referring to the unfathomable judgments of God. His other works include *De Eucharistia*; *De Generibus et Speciebus* (in-

cluded in V. Cousin's *Ouvrages inédits d'Abélard*, Paris 1836); and *Sententiae* (extracts printed in G. Lefèvre's *Les variations de G. de Champeaux*, Paris 1898).

He is considered the first prominent dialectician of the realist sect.

Consult Michaud, E., *G. de Champeaux et les écoles de Paris au XIII^e*, 2d ed. (Paris 1868).

CHAMPERICO, chām-pā-rē'kō, town, Guatemala, in Retalhuleu Department, situated on the Pacific Coast, 23 miles southwest of the city of Retalhuleu. It has a beautiful beach, and is popular with hunters and fishermen. Exports include coffee and sugar. Pop. (1950) 982.

CHAMPERTY, chām'pēr-tī, or **CHAMPARTY** (Lat. *campi partitio*, a division of lands), in law, a bargain with the plaintiff or defendant in any suit to have part of the land, debt, or other thing sued for, if the party that undertakes the suit prevails therein, the champertor carrying on the party's suit at his own expense. It is a species of maintenance, and is generally held to be illegal both in courts of common law and equity; but in some of the states of the United States such agreements are recognized by law, and the tendency is toward freedom of action in these as well as other contracts. See also MAINTENANCE.

CHAMPFLEURY, shān-flū-rē' (pseudo-nym of JULES FLEURY-HUSSON), French novelist and miscellaneous writer: b. Laon, Sept. 10, 1821; d. Paris, Dec. 5, 1889. His story of *Chien-Cailou* (1847) was in Victor Hugo's opinion a masterpiece of realistic description. He wrote an autobiographical account of his youthful years in *Confessions de Sylvius* (1849). But his *Les bourgeois de Molinchart* (1855), a satiric delineation of the provincial bourgeoisie, made him famous. He was a pronounced realist, his other works including *Les oies de Noël* (1853); *Les amoureux de Saint Péline* (1859); *Monsieur Tringle* (1866); *Fanny Minoret* (1882). He at one time owned a ceramic factory and wrote a book on design and ceramics, *Bibliographie céramique* (1881).

CHAMPIER, shān'pē-yē, Symphorien, French poet and historian: b. Saint Symphorien-sur-Coise, Rhône, 1472; d. Lyon c.1540. Famed as a physician, with powerful friends at court, and an ample fortune, he took delight in literature and the society of literary men, himself writing a series of poems entitled *Virtuous Ladies* (1503), containing four divisions dedicated to love. His best history is *Les gestes, ensemble de la vie du preux chevalier Bayard* (1525).

CHAMPIGNON, shām-pīn'yūn, the French name for the mushroom, and the term commonly applied to the mushroom *Marasmius oreades* in the United States.

CHAMPION, shām-pīn'yūn, one who undertakes to defend, in combat or by argument, another person, a doctrine or a cause. In the rudest state of society men avenge their own wrongs without restraint. The first step commonly made toward a better state of things in the rude beginnings of political society is to confine this right within certain bounds, and allow it to be exercised only with certain formalities. This

was done by the feudal institutions of Europe, which recognized in many circumstances, under the toleration of the church itself, the right of private combat, which became a common means of settling disputes. It was not always waged, however, by the contending parties and, in the cases of felony, or inability to fight because of age or sex, the question was left to a more rational mode of settlement. But in the writ of right, the last and most solemn decision respecting real property, the tenant was required to produce his champion, who threw down his glove as a challenge to the champion of the defendant; the latter, by taking it up, accepted the challenge. The law authorizing judicial combat, though fallen into disuse, was kept on the English statute book until 1819.

Even the right of the English crown was in some degree put in issue by appeal to judicial combat; and the appearance of a champion offering battle to anyone who would gainsay the right of the king to the crown was until recently a part of the ceremonial of the coronation. The champion's function was to ride into Westminster Hall in full armor, throw down his gauntlet and proclaim readiness to defend the title of the sovereign against anyone disputing it. After George IV's coronation, the champion lost this function and merely walked in the coronation procession bearing the standard of England (red flag with three gold lions). At the coronation of Elizabeth II in 1953 he bore the Union Standard (United Kingdom flag).

CHAMPIONNET, shān-pyô-ně', Jean Antoine Étienne, French soldier: b. Valence, France, 1762; d. Antibes, Jan. 9, 1800. Having entered the army at an early age, Championnet took part in the siege of Gibraltar (1780-1783). In 1793, as a brigade commander in the Rhine campaign, he distinguished himself at Weissenburg. In 1798 he was named commander in chief of the "Army of Rome" which was to protect the young Roman republic against Naples and its allies. Capturing Naples in January 1799, he set up the Parthenopean Republic (q.v.) there, but was arrested by the Directory's commissioner attached to his army. Acquitted unanimously at his trial, he became commander in chief of the "Army of the Alps," hardly more than a paper force. The defeat of Barthélemy C. Joubert's army at Novi by the Russians and Austrians (Aug. 15, 1799) forced him to retreat to Nice where he died of an epidemic that decimated his troops.

CHAMPION'S HILL, Battle of, fought on May 16, 1863 at Champion's Hill near Vicksburg, Miss., between the Union troops under Gen. Ulysses S. Grant and the Confederates under Gen. John C. Pemberton.

After the failure of several attempts to capture Vicksburg earlier in the war, General Grant decided to cut loose from his supply base at Memphis, Tenn. (March 29, 1863), crossed the Mississippi above Vicksburg, and marched through the swamps of the Louisiana shore down to a point where he could cross to Bruinsburg, Miss., 32 miles below Vicksburg (April 30). The Union Fleet, meanwhile, had run the Vicksburg batteries in the night of April 16 with supplies for Grant, and had assisted the troops in crossing the river.

On May 1, Grant marched to Port Gibson,

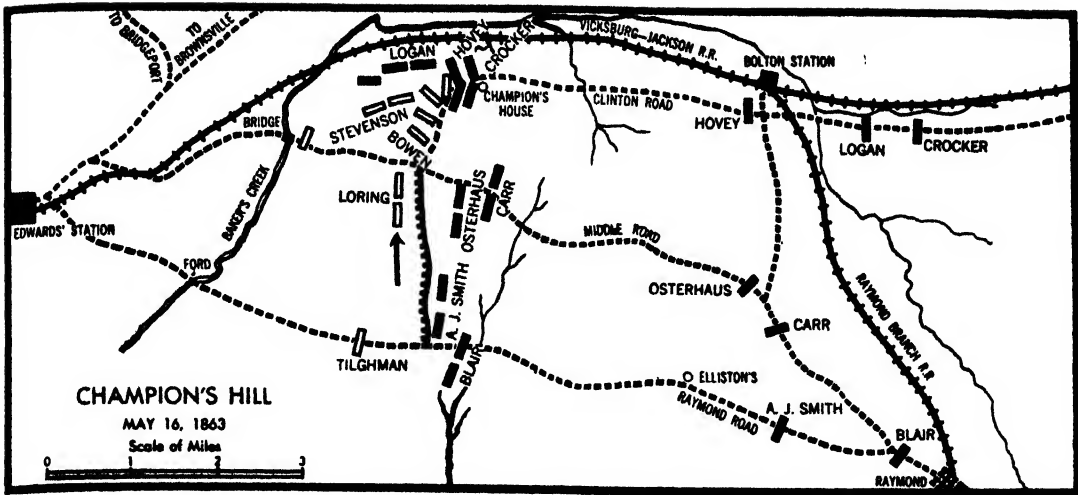

defeating Confederate troops under Gen. J. S. Bowen; then continued his march in a northeasterly direction and on May 12 encountered and defeated enemy forces at Raymond. The important railway junction of Jackson, Miss., was taken two days later and all supplies useful to the enemy were destroyed before Gen. Joseph E. Johnston could get there. The latter sent a dispatch to General Pemberton advising that the two armies should try to unite on the Jackson-Vicksburg railroad near Clinton. Grant, however, had intercepted this dispatch and decided at once to move toward Pemberton, while the latter, anxious to hold Vicksburg and the Big Black River line, questioned the wisdom of such a movement and hesitated to follow Johnston's advice. Upon the suggestion of Carter L. Stevenson and William W. Loring, Pemberton decided to move on Grant's rear in the direction of Raymond, and on May 15 advanced for that purpose.

Early on the next morning Pemberton received another dispatch from Johnston, urging him to move toward Clinton, where Johnston hoped to meet him with about 6,000 men. Pemberton immediately turned back his trains to Edward's Station to get the road leading northward to Brownsville, but had scarcely done so, when P. J. Osterhaus' and A. J. Smith's divisions of Grant's army made their appearance on the Raymond road and attacked his skirmishers, whereupon Pemberton suspended his movement to join Johnston. Continuing the rearward movement of his trains, he formed for battle with a force of about 17,500 men on the general line of a crossroad connecting the Raymond and Clinton roads.

The position of Grant's army on the night of May 15 was as follows: Alvin P. Hovey's division was at Bolton on the Clinton road; John A. Logan's and C. C. Crocker's were on the same road a few miles in Hovey's rear; Osterhaus' was on a crossroad, halfway from Raymond to right, covering the Raymond road, and Bowen in the center and Stevenson on the left on the northern point of a narrow ridge known as Bolton; Eugene A. Carr's was a short distance in Osterhaus' rear; and the divisions of Smith and Francis Preston Blair were west of Raymond on the Edward's Station road. These seven divisions numbered about 32,000 men on the three roads converging on Edward's Station, the Raymond road on the south, the Middle road, and the Clinton road on the north.

Early in the morning of May 16, Grant, at Clinton, hearing that Pemberton was marching to attack him, sent orders for James B. MacPherson, with the divisions of Logan and Crocker, to close up rapidly on Hovey, and for the four divisions under John A. McClernand on the Raymond and Middle roads to move forward cautiously. He then hastened by the Clinton road to the front. A. J. Smith, advancing on the Raymond road, attacked and drove in Loring's skirmishers about 8 A.M., and Osterhaus on the Middle road engaged those in his front. Artillery was brought up and opened fire; but McClernand, doubtful whether Grant wanted him to bring on a general engagement, deferred attack until 2 P.M., when he received Grant's order to attack. He then ordered Smith and Osterhaus to press for victory, but meanwhile the battle was being fought out and decided on Champion's Hill.

Advancing on the Clinton road, Hovey began

skirmishing with Stevenson about 10 A.M. and started to form line for a general attack, but was directed by Grant to wait until McClernand could be heard from. Logan came up at 11 A.M.; nothing had been heard from McClernand, so line was formed for a general attack, Hovey south of Clinton road with Logan on his right. About noon Hovey advanced with great spirit, charging up Champion's Hill. After a hard contest with varying success, he drove back Stevenson's right, capturing 11 guns. Logan, who had worked around on the north side of the hill, attacked and drove back Stevenson's left, and captured 7 guns. The positions thus gained were held until 2 P.M.

Meanwhile Stevenson, compelled to take ground to the left in order to meet Logan's flank movement and cover the road to Baker's Creek and Edward's Station, had induced Pemberton to draw Bowen to the left and close the interval between the two divisions, and Loring was ordered to close in on Bowen. It was after 2 P.M. when Bowen closed in on Stevenson and his two leading brigades. Francis M. Cockrell's and Green's, attacked Hovey furiously and drove him back down the hill. Hovey contesting every foot, but forced to abandon 9 of the captured guns.

As Hovey fell back, two brigades of Crocker's division came to his support and the Confederates were checked. Massed artillery now poured such an effective enfilading fire upon Stevenson's line that it was much shaken. Hovey and Crocker again charged up the hill, breaking the desperate resistance of Stevenson and Bowen.

Seeing his left defeated, Pemberton at 3 P.M. ordered a general retreat, Loring to cover it. Before this, Loring, leaving Gen. Lloyd Tilghman's brigade on the Raymond road to oppose Smith and Blair, had already with two brigades nearly closed up on Bowen. When the retreat began, he was forming his men between the Clinton and Raymond roads. Attacked by Osterhaus, he soon gave way, falling back to the Raymond road. Meanwhile Smith, advancing on the Raymond road, had defeated and killed Tilghman. Loring reunited his command and retreated on that road, but on approaching the ford of Baker's Creek he found it in Union possession. Realizing he had been cut off from Pemberton's army, he moved southward, abandoning his artillery, and on May 19 joined Johnston, who meanwhile had reoccupied Jackson. Stevenson's and Bowen's

men retreated to the Big Black, Grant following as far as Edward's Station, where darkness ended the pursuit. Continuing the pursuit next day, Grant defeated Pemberton at the Big Black Bridge, and on May 19 invested Vicksburg.

E. A. CARMAN.

CHAMPLAIN, shām-plān'; Fr. shān-plān', Samuel de, French explorer and colonizer: b. Brouage, Saintonge, France, about 1567; d. Quebec, Canada, Dec. 25, 1635. Champlain served in the army of Henry IV under Marshals Jean d'Aumont and Charles de Cossé, comte de Brisac, from 1593 to 1597. In January 1599, however, he entered the Spanish service, commanding a vessel that sailed to the West Indies, Mexico, and Panama. Back in France in 1601, he prepared a record of the cruise. This work, *Bref discours des choses plus remarquables que Samuel Champlain de Brouage a reconnues aux Indes Occidentales*, has been preserved in the library at Dieppe in manuscript form; an English translation appeared 1859.

Commissioned by Aymar de Clermont, seigneur de Chaste (Chastes), who was governor of Dieppe and held a royal patent for the fur trade and the colonization of the French territories in North America, Champlain set out for Canada in March 1603. There he explored the St. Lawrence River by boat, reaching Lachine Rapids below Lake St. Louis as the extreme point of his trip, and making friends with the Indians along the way. On his return to France, he published a book about his trip under the title *Des sauvages, ou voyage de Samuel Champlain de Brouage fait en la France Nouvelle*. De Chaste had died during Champlain's absence, and Pierre du Guast, sieur de Monts, had received the privileges for Canada.

In 1604, Champlain and de Monts coasted the shores of Nova Scotia, wintered on the island of St. Croix, and the next summer founded a colony at Port Royal (now Annapolis Royal). They spent the next two years making surveys and charts of the coast as far as Cape Cod. Meanwhile, the king, under pressure of Basque and Breton merchants, had withdrawn de Monts' privileges and opened the fur trade to the merchant marine. When de Monts and Champlain returned to France, however, they secured a restoration of the patent, with limitations.

Champlain subsequently sailed, for the third

time, to Canada, the main purpose of this trip being exploration for settlement. In 1608 he founded Quebec; owing to the rapid development of its fur trade, the settlement achieved an early prosperity. The following year, accompanying a war party of Algonquins and Hurons, he discovered Lake Champlain, and participated in a battle fought by his allies with the Iroquois. Stunned by the miraculous power of the white men's firearms, the Iroquois soon broke and fled in confusion. However, their bitter hatred for the French resulting from this battle was to become a severe handicap to the colony.

In the fall of 1609, Champlain returned to France to recruit colonists, a number of whom he brought to Canada in the following spring. In 1611 he founded, near Mount Royal, Place Royale, which was destined to become Montreal, and continued his expeditions covering a good deal of the country. Realizing that the future of the young colony depended to a great extent upon proper administration, he sought the protection of one of the great nobles with influence at court. After certain negotiations King Louis XIII, in 1612, appointed Louis de Bourbon, the comte de Soissons, lieutenant general of New France, and he in turn made Champlain his representative and commander at Quebec. After Soissons' sudden death, the post was given to Henry de Bourbon, prince de Condé, who retained Champlain's services.

In the following years Champlain continued his expeditions, fought with his Algonquin and Huron allies against the Iroquois, traversed a great part of what is now New York State, and eventually reached the north end of Lake Huron. During this period he made several brief visits to France. He fortified Quebec in 1620 and was made governor of New France in 1627. Two years later, however, he was obliged to surrender Quebec to an English fleet and was himself made prisoner. Brought to England, he was a captive until 1632. On his release he returned to Canada to resume his duties as governor. (See also CANADA—*Era of Early Discovery*.)

A complete edition of Champlain's works, edited by Abbé C. H. Laverdière, was published in 6 volumes in Quebec (1870). An English translation by C. P. Otis appeared in Boston in 3 volumes (1878-1882).

Consult Parkman, F., *Pioneers of France in the New World* (Boston 1865); Gravier, G., *Vie de Samuel Champlain* (Paris 1900); Dionne, N. E., *Samuel Champlain, fondateur de Québec*, 2 vols. (Québec 1891-1906); and Flenley, Ralph, *Samuel de Champlain, Founder of New France* (Toronto 1925).

CHAMPLAIN, Battle of Lake, in the War of 1812. Lake Champlain saw little military activity during the first two years of the war, both British and Americans being busy with construction of armed vessels. By mid-August of 1814, however, Sir George Prevost, governor in chief of the Canadas and commander in chief of British forces, with 11,000 men was ready to invade the United States and began his advance up the western side of the lake. At Plattsburg he faced an enemy force of approximately 1,500 American regulars and about 2,500 militia under Brig. Gen. Alexander Macomb. At the same time both fleets had been completed and were ready for battle. The British Fleet under Commodore George Downie followed the movement of the land troops; while the American ships under Master Commandant Thomas Macdonough

anchored inside the entrance of Plattsburg Bay.

Prevost's forces reached Plattsburg on Sept. 6, 1814, and for four days the two armies engaged in continuous skirmishing, Prevost not wanting to attack the strong fortifications, erected by Maj. Gen. George Izard and strengthened by Macomb, until he had the support of Downie's fleet. The latter arrived early on the morning of September 11, and at about 9 A.M. the two fleets became heavily engaged. Downie's force included the 37-gun *Confiance*, the *Linnet*, the *Chubb*, and the *Finch*, as well as 12 smaller vessels, while the American Fleet consisted of the 26-gun *Saratoga*, the *Eagle*, the *Ticonderoga*, the *Preble*, and 10 gunboats.

Macdonough had outmaneuvered Downie merely by the selection of an anchoring position which denied the enemy the advantage of their superiority in long-range guns, the British having 60, compared with 45 for the Americans. Before opening fire Downie was compelled to sail his ships 300 yards closer to his foe's than would have been necessary had the action been fought in the open lake with both fleets under sail. The decision was reached after the action had continued for an hour and a half, both sides suffering severely. Macdonough then wound his flagship, the *Saratoga*, and brought to bear on the *Confiance* an uninjured broadside. Too damaged to attempt a similar maneuver, Downie's flagship was forced to surrender; his other three large vessels then struck their colors and the galleys took to flight.

The casualties on the American side were 52 killed and 58 wounded, while the British lost 57 killed and 92 wounded. Early in the fight the *Eagle* and the *Preble* were forced out of action. Macdonough's victory was decisive, forcing Governor Prevost's army to retreat to Canada and forestalling any claim by the British government for territorial adjustments in the Lake Champlain area at the Treaty of Ghent (1814). Macdonough received many honors for his victory, including the thanks of Congress and promotion to a captaincy, the commission to date from September 11.

Consult Mahan, Alfred T., *Sea Power in Its Relation to the War of 1812*, 2 vols. (London 1905); Clark, George R., and others, *A Short History of the United States Navy* (Philadelphia 1911).

CHAMPLAIN, Lake, a body of water lying within the states of New York and Vermont and the Province of Quebec, Canada. It forms part of the boundary of the two American states, and about six miles of its northern end extends into Canada. Its extreme length from south to north is about 125 miles and it is from 400 yards to 14 miles wide; its greatest depth reaches about 600 feet. Scattered over the whole area of about 600 square miles are more than 50 islands; the altitude of the lake is 90 feet. It is bordered by the Green Mountains on the east, by the Adirondacks on the west; its waters are carried northward by the Richelieu River to the St. Lawrence. The Chambly Canal and the New York State Barge Canal System connecting with the lake enable barges and small yachts to voyage between New York City and Montreal. The chief cities on the lake are Burlington, Vt., and Plattsburg, N. Y. The only highway bridge over the lake, which connects Crown Point, N. Y., with Chimney Point, Vt., was opened in 1929.

Lake Champlain was discovered in 1609 by the French explorer Samuel de Champlain. It was

the scene of many battles from early colonial times, having been one of the main invasion routes between Canada and the English colonies that became the United States.

CHAMPLAIN STAGE, the name given by American geologists to the subsidence that was a feature of the close of the Glacial epoch in New York, New England, Ontario and Quebec. At the beginning of the Glacial epoch the elevation of this section of the continent may have been greater than now, but when the ice-sheet finally retreated the sea extended up the Saint Lawrence River nearly to Lake Ontario, and the lower Ottawa River and Lake Champlain were occupied by salt water. The stage is named from the lines of old sea beaches containing whale and walrus bones, thus showing the submergence, typically developed about Lake Champlain. The total amount of the depression varied, being greatest over the Saint Lawrence Valley. About New York Harbor the coast was depressed fully 70 feet; at Albany 355 feet. Along the Maine shore the land was 150 to nearly 300 feet lower than now, and in the Saint Lawrence Valley the depression was over 500 feet, making allowance for the previous elevation the total depression in the Saint Lawrence Valley reached 1,500 feet. The climate of Champlain time was probably warmer and moister than that of the present. On the Pacific coast are evidences of depression in the region about Mount Saint Elias, shells of Champlain species being found at an altitude of 5,000 feet. (See also GLACIAL PERIOD; QUATERNARY). The term Champlainic system was proposed to replace Ordovician system, but the proposal did not meet with general acceptance.

CHAMPLEVE, shān-lē-vā', **ENAMELS**. See ART ENAMELS.

CHAMPLIN, John Denison, American author: b. Stonington, Conn., Jan. 29, 1834; d. Jan. 8, 1915. He was graduated at Yale in 1856, and admitted to the bar in 1859. In 1864 he became associate editor of the *Standard* at Bridgeport, Conn. He afterward published *The Sentinel* (1865-1869) at Litchfield, Conn. He devoted himself entirely to literature from 1869, and became associate editor of the *American Encyclopaedia* (1875). Author *Young Folks' Cyclopaedia of Common Things* (1879); *Young Folks' Catechism of Common Things* (1880, 1906); *Young Folks' Cyclopaedia of Poems and Places* (1880, 1899, 1911); *Young Folks' Astronomy* (1881); *Young Folks' History of War for the Union* (1881); *The Chronicle of the Coach* (1886); *Young Folks' Cyclopaedia of Games and Sports* (with Arthur E. Bostwick, 1890); *Young Folks' Cyclopaedia of Literature and Art* (1901); *Young Folks' Cyclopaedia of Natural History* (1905); *The Tragedy of Anne Hutchinson* (1911). Editor *Fox's Mission to Russia* (1873); *Cyclopaedia of Painters and Paintings* (1886-1888); *Cyclopaedia of Music and Musicians* (1888-1890); *Liber Scriptorum* (1893). Associate editor *The American Cyclopaedia* (1873-1877); *The Standard Dictionary* (1892-1894); *Orations, Addresses, and Speeches of Chauncey M. Depew* (1910).

CHAMPNEY, chāmp'nī, Benjamin, American artist: b. Ipswich, N. H., Nov. 29, 1817;

d. Woburn, Mass., Dec. 14, 1907. He went to Boston in 1834, and for three years worked in a lithographic establishment. From 1841 to 1848 he studied painting in Paris and Italy, exhibiting several times in the Paris Salon. He worked chiefly in landscape and flower painting, and his White Mountain paintings, which are owned in and around Boston, are famous. Published *Sixty Years' Memories of Art and Artists* (1900).

CHAMPNEY, Elizabeth Williams, American author: b. Springfield, Ohio, Feb. 6, 1850; d. Oct. 13, 1922. She was graduated at Vassar College 1869, traveled extensively in Europe and wrote many papers for *Harper's* and the *Century*. She was president of the board of managers of the Messiah Home for Children. She published *The Bubbling Teapot*; *Howling Wolf and His Trick Pony*; *All Around a Palette*; *Bourbon Lilies*; *Rosemary and Rue*; *In the Sky Garden*; *Vassar Girls Abroad*; *Witch Winnie* series (7 vols.); *Dames and Daughters of Colonial Days*; *Romance of the Feudal Châteaux* (1900); *Romance of the Renaissance Châteaux* (1901); *Romance of the Bourbon Châteaux* (1903); *Romance of the French Abbays* (1905); *Romance of Italian Villas* (1906); *Romance of Roman Villas* (1908); *Romance of Imperial Rome* (1910); *Romance of Old Belgium* (1915).

CHAMPNEYS, champ'nēz, Basil, English architect: b. 1842; d. April 5, 1935. He was educated at Trinity College, Cambridge, and after studying architecture with the architect Prichard, of Llandaff, began the practice of his profession in 1867. Important works of his are the divinity and literary schools of Newnham College and the Archaeological Museum at Cambridge; Indian Institute, Robinson Tower at New College and Mansfield College at Oxford; Rylands Library in Manchester; Butler Museum at Harrow; and Quincentenary buildings at Winchester College. He was cathedral architect at Manchester. He published *A Quiet Corner of England*, a delightful description of Rye and Winchelsea; *Henry Merritt: Art Criticism and Romance*; *Coventry Patmore: Memoirs and Correspondence*.

CHAMPOLLION, shān-pō-lyōn', Jean François, French Egyptologist: b. Figeac, Lot, France, Dec. 23, 1790; d. Paris, March 4, 1832. At an early age he devoted himself to the study of Hebrew, Arabic, and Coptic. In 1807 he read a paper before the Academy of Grenoble on the ancient Egyptian geographical names, which he endeavored to explain by the Coptic. He then went to Paris, where he continued his Oriental studies, paying particular attention to the Coptic, and endeavoring through it to find the key to the Egyptian hieroglyphics. In 1809 he became professor of history at Grenoble, but soon retired from this post and went to Paris, where he devoted himself almost exclusively to the study of Egyptian antiquities. Assisted by the trilingual inscription of the Rosetta stone he at length discovered the key to the graphic system of the Egyptians, the three elements of which—figurative, ideographic, and alphabetic—he expounded before the Institute of France in a series of memoirs in 1823. These were published in 1824 at the expense of the state, under the title of *Précis du système hiéroglyphique des Anciens Égyptiens*. In 1824 he went to Italy, and investigated the collections of papyri and other Egyptian antiqui-

ties in the principal cities there. In 1826 Charles X appointed him to superintend the new department of Egyptian antiquities in the museum of the Louvre. In 1828 M. Champollion went as director of a scientific expedition to Egypt, at the expense of the king. He was admitted a member of the Academy of Inscriptions in 1830. In 1831 the chair of Egyptian archaeology was created for him in the Collège de France. His principal works are *Grammaire Égyptienne* and *Dictionnaire hiéroglyphique*, both published after his death.

CHAMPOLLION FIGEAC, fē-zhàk, Jean Jacques, French archaeologist, elder brother of the preceding: b. Figeac, Lot, Oct. 5, 1778; d. May 9, 1867. He completed his studies at Grenoble, published his first archaeological memoirs in 1803, and was named successively librarian of Grenoble, professor of Greek literature, secretary and dean of the faculty of letters of the same town. He took an active part in everything connected with science and letters in the department of the Isère. He acted as secretary to Napoleon in drawing up under his instruction the account of his memorable passage from Elba to Grenoble. In 1828 a place was made for him as keeper of the manuscripts in the Royal Library, and shortly afterward he was installed in the chair of Palaeography in the École des Chartes. He was made an officer of the Legion of Honor in 1866. His principal works are *Antiquités de Grenoble* (1807); *Annales des Lagides* (1819); *L'Égypte Ancienne et moderne* (1850); besides several other interesting works on Oriental history.

CHAMPS ELYSEES, shānz'ā'lē'zā' (Fr. "Elysian Fields"), an avenue in Paris, with its surrounding gardens. It extends from the Place de la Concorde to the Arc de Triomphe de l'Etoile, a distance of one and a quarter miles, and is a famous public resort and promenade. The lower end forms a park, on either side of which are placed the Palais de l'Elysée and the two Palais des Beaux Arts, occupying the site of the old Palais de l'Industrie. It became the property of the Crown in 1616 and was ceded to the city in 1828.

CHAN CHAN or **GRAN CHIMU**, former capital of the Chimus, about two miles from Trujillo, Peru. The origin of the Chimus is unknown, but the ruins of their capital, well preserved by a dry climate, show that their civilization was highly developed, and irrigation widely practiced in this quasi desert region. The city, built entirely of adobe bricks, covers some eleven square miles and probably housed upwards of 250,000 people. Centuries of constant warfare between the Andean Incas and the coastal peoples culminated in the capture by the Incas of Paramonga, the Chimu fortress near present-day Supe, about 1400 A.D., after which Chan Chan was taken and abandoned, the population being exterminated or redistributed in other parts of their empire.

CHANCA, chān'ka, Dr. (believed to have been DIEGO ALVAREZ CHANCA), Spanish physician: b. Seville; who became a companion of Columbus on his second voyage in 1493. One of the principal authorities for this voyage is the letter which he wrote to the Catholic college at Seville, giving an account of his journey. No

record has been kept of his subsequent life.

CHANCE, in its original and strict meaning, is a description of events which cannot be subsumed under any law, causal or theological. Strictly speaking, it is an idea which few men would now be disposed to admit as corresponding to anything which really exists; the religious mind excluding it as inconsistent with the belief in the divine government, and the philosophical mind rejecting it as inconsistent with a recognition of universal laws of causation. As a word, however, it has always been, and always will be, popularly accepted as a term denoting an unknown cause. For the mathematical theory of events which are chance in this derived sense, see **PROBABILITY**, **THEORY OF**.

CHANCE, a novel by Joseph Conrad (Teodor Josef Konrad Korzeniowski) (q.v.), published in 1913.

One of Conrad's longer and more elaborately constructed novels, it is in accordance with his own published statement, the life story of Flora de Barral, as seen through the eyes of several persons, including the author's faithful and articulate *alter ego* and narrator, the ubiquitous Marlow. It is also the story of Captain Roderick Anthony, whose dream it is to embrace a "wisp of mist," as he very romantically characterizes the slim, dark, pale, unhappy, and insubstantial Flora, whom he marries and takes to sea with him as a wife in name only, for the better part of two leisurely merchant voyages under sail and under circumstances of ever increasing tension. The resolution, handled with much skill and with a directness absent from the greater part of the tale, renders the twain one flesh and eliminates by suicide Flora's father, whose term of imprisonment for alleged financial irregularities on the grand scale, has for so long cast a deep shadow over his daughter's life.

Captain Anthony's sister, Mrs. Fyne, and his Second Mate aboard ship, young Charles Powell, are, in addition to Marlow, important to the reader's full understanding of the principal characters.

By more than one critic, *Chance* has been considered somewhat too long for its material and there can be no doubt that the narrative method is complicated, particularly in the early chapters. The climax, however, coming after so thorough a preparation, is probably the stronger for it, and there are in the book a number of instances of the true Conrad literary power which, at its best, is remarkable for its immunity from the withering touch of time.

CHANCE ACQUAINTANCE, A, a story by William Dean Howells, published in 1873. This agreeable and entertaining sketch contains many charming descriptions of the picturesque scenery and places about Quebec.

CHANCEL, that portion of a church occupied by the clergy, and often separated from the nave and aisles by screens of carved stone or oak. The screen separating the chancel from the nave is called the rood screen, because anciently a rood or large crucifix was usually placed on it, accompanied with two figures representing Saint John and the Virgin Mary. In the chancel were situated the high altar, the sedilia, or seats for the officiating clergy, and the piscina, in which the water used for washing

the hands of the celebrant was poured. It usually contains carved seats or stalls, occupied by the clergy not engaged in the services. These are enriched with carvings and have canopies of carved oak. The chancel occupies the same place with the apsis in the ancient basilicas, and was called so from the *cancelli*, or rails used in the early churches to separate the clergy from the laity. The chancel is always at the east end of the church (churches being technically considered as having their major axes extending east and west) and is often constructionally a separate building opening from the nave with a lower roof elevation and raised several steps above the nave.

In architecture the term is employed as denoting the space for clergy and choir, separated by a screen from the body of the church.

CHANCELLOR, Charles Williams, American physician: b. Spottsylvania County, Va., Feb. 19, 1831; d. Washington, D.C., Jan. 3, 1915. He studied at Georgetown College, 1848, and at the University of Virginia, 1851; was graduated from Jefferson Medical College, Philadelphia, 1853. During the Civil War he was medical director of Gen. George Edward Pickett's division of the Confederate Army, 1863-1865. He was professor of surgery in, and dean of, Washington University, Baltimore, 1868-1875; secretary of the Maryland State Board of Health, 1875; president of the Maryland State Insane Asylum, 1880; and United States consul at Le Havre, France, 1893-1897.

Among his numerous reports and articles on medical and sanitary topics are *Report upon the condition of the Prisons, Reformatories and Charitable Institutions of Maryland* (1875); *Contagious and Infectious Diseases* (1878); *Mineral Waters and Seaside Resorts* (1883); *Drainage of the Marshlands of Maryland* (1884); *Heredity* (1886); and *Sewerage of cities* (1886).

CHANCELLOR, Richard, English navigator; d. at sea, Nov. 10, 1556. Brought up in the household of the father of Sir Philip Sidney, who regarded him highly, he was chosen, in 1553, as captain of the *Edward Bonaventure* and "pilot-general" of Sir Hugh Willoughby's expedition in search of a northeast passage to India. The ships were parted in a storm off the Lofoten Islands and Chancellor, after waiting seven days at Vardoehuus, the rendezvous agreed upon, proceeded alone into the White Sea and traveled thence overland to the court at Moscow, where he was very hospitably treated, and was able to conclude a treaty giving freedom of trade to English ships. His interesting account of Russia was published in Richard Hakluyt's *Principal Navigations, Voyages, and Discoveries of the English Nation* (1589). The next spring Chancellor rejoined his ship and returned to England, where his hopeful reports led to the establishment soon after of the Muscovy Company. In the summer of 1555 he made a second voyage in the *Edward Bonaventure* to the White Sea, and was at Moscow once more in the succeeding winter. In July 1556, he set sail on his voyage homeward, but was lost in the wreck of his ship in Aberdour Bay off the Aberdeenshire coast.

CHANCELLOR, an officer supposed to

have been originally a notary or scribe, under the Roman emperors and named *cancellarius*, because he sat behind a lattice—called in Latin *cancelli*—to avoid being crowded by the people. There are, however, other derivations of this title. Whatever may have been its origin, the office and name of chancellor were undoubtedly known at the court of the Roman emperors, where the title seems to have signified originally a chief scribe or secretary, who was afterward invested with several judicial powers and with superintendence over the other officers of the empire. From the Roman Empire the title and office passed to the Roman Catholic Church and hence every bishop has to this day his chancellor, the principal judge of his consistory. When the modern kingdoms of Europe were established upon the ruins of the empire, almost every state preserved its chancellor, with different jurisdictions and dignities according to their different constitutions. In all he seems to have had the supervision of all charters, letters, and such other public instruments of the crown as were authenticated in the most solemn manner, and therefore, when seals came into use, he had always the custody of the king's great seal. This officer has now great authority in all the countries of Europe.

Great Britain.—Lord High Chancellor of Great Britain (originally of England).—He is the first judicial officer of the crown and exercises an extensive authority as head of the judiciary. He ranks as first lay person of the state after the blood royal. He is always one of the commissioners appointed to represent the sovereign in opening and closing Parliament or giving the royal assent to bills. He is created by the delivery of the great seal into his custody. In like manner the act of taking away the seal formally terminates his office. He is a Cabinet Minister and a privy councillor in virtue of his office, is speaker of the House of Lords by prescription and in that office has the right to address their lordships as well as to vote. He vacates office with the ministry which appoints him. He has a salary of £10,000 and, no matter how brief his tenure of the office may be, is entitled to a pension of £5,000 a year on vacating it. When Sir Robert Finlay was nominated in December 1916 for the office in the Lloyd George government, he is believed to have created a precedent in stipulating waiver of the pension in his case. The lord chancellor presides over the Court of Appeal and the privy council in the exercise of judicial functions. He has the appointment of all justices of the peace in the kingdom, is visitor, in the king's right, of all royal foundations and patron of all crown livings, the higher dignities in the Church of England being nominated by the prime minister. The office having in early times been always filled by ecclesiastics (for no others were then capable of an employment requiring so much writing), he became keeper of the king's conscience; and by special appointment he now exercises a general superintendence as guardian over all infants, idiots, and lunatics, though these latter powers are not necessarily attendant on his office, as Sir William Blackstone seems to have imagined, but can be delegated by the crown to any other judicial officer. In fact, they were so delegated even as late as the reign of James I when the seals were held by Dr. John Williams, then dean of Westminster, and afterward bishop of Lincoln. Not infrequently the

great seal has been put in commission, and was last so on the resignation of Edward, 1st baron Thurlow, in 1793. One vice chancellor was appointed to preside in the courts of equity by 53 George III, c. 24, and two by 5 Vict. c. 5, § 19. The two last-mentioned were at first subordinate vice chancellors, but afterward they were all made of equal rank. They sat in separate courts, and an appeal lay from their decisions to the lord chancellor. They latterly sat in the chancery division of the Supreme Court of Judicature. See CHANCERY; SUPREME COURT OF JUDICATURE.

Chancellor of the Exchequer is the finance minister of the Cabinet and as all questions of supply originate in the House of Commons, a peer is ineligible for this office, which originated in the separation of the chancery from the exchequer in the reign of Henry III. The holder of this office in recent years is generally held as having the reversion to the premiership, with which it has occasionally been conjoined.

Chancellor of the Duchy of Lancaster is the representative of the crown in the management of the lands of the duchy, which are the personal property of the sovereign. The office is a sinecure and is usually held by a minister of Cabinet rank, of high standing in the country, but who is unable to bear the physical strain incident to the management of a heavy department.

Chancellor of the Order of the Garter and Other Military Orders, an officer who seals the commissions and the mandates of the chapter and assembly of the knights of the order, keeps the register of their proceedings and delivers their acts under the seal of their order. The title chancellor is given, in England, to several officers of other bodies.

Chancellors of Ireland and Scotland.—There was formerly a lord high chancellor of Ireland who was the head of the judicial bench, with a salary of £8,000. His office was abolished under the Free State Constitution. The chancellorship of Scotland was abolished at the union. The Scottish chancellor had no independent jurisdiction in equity, as there has never been a separate court of equity in Scotland; but he presided in Parliament, and was head of all the courts of judicature and of the Scottish office of chancery, in which all charters and other writs appointed to pass the great seal were recorded.

Chancellors of Other European Countries.—The chancellor was one of the highest officers in the German states and by the influence of his office was one of the most important. In Germany this dignity was from the remotest times vested in one of the higher clergy, until the head of the German clergy, the archbishop and elector of Mainz, united it permanently with his office as archchancellor of the empire. The two other spiritual electors held the same dignity, but it was merely titular; the archbishop of Cologne, as archchancellor of Italy; the archbishop of Trèves, as archchancellor of Gaul and Arles, that is, the kingdom of Burgundy, once belonging to Germany. The archchancellorship of Mainz, on the contrary, had important duties attached to it—the direction of the Diet and of the public business, as well as of all imperial chanceries. The elector appointed a vice chancellor, who was the actual minister of the empire at the imperial court. In the German Empire (1871–1918) the chancellor (*Reichskanzler*) was the president of the Federal Council (*Bundesrat*), and had the general conduct of the imperial ad-

ministration. All laws of the empire, after being sanctioned by the emperor, had to be countersigned when promulgated by the chancellor.

The chancellor of France held a position analogous to that in England, was the highest officer of state, and the only one who, when once appointed, could not be dismissed. In case, therefore, it was desired to remove him from participation in affairs, a keeper of the seals (*garde des sceaux*) was appointed. As the chancellor was properly the minister of justice, he was chosen from the body of jurists. A relic of his spiritual character was that all his furniture, liveries, and even his coach, were black.

Universities.—The *Chancellor of a University* is an official at the head of the university, generally a man of rank, whose duties are more or less nominal, but who is regarded as conferring the degrees. At Oxford his duties are almost entirely discharged by the vice chancellor, the chancellor's own acts being limited to the signing of diplomas. Under the vice chancellor are four pro-vice chancellors, nominated by him from among the heads of colleges, to one of whom, in his absence from the university, he delegates his authority. The chancellor of Cambridge University, whose duties are very similar to those of the Oxford official, is elected biennially by the senate, but there is no instance, at least in modern times, where a re-election has not taken place.

CHANCELLORSVILLE, The Battle of. The Chancellorsville campaign included the Battle of Chancellorsville, May 1–3, 1863, the action at Marye's Heights, May 3, 1863, and the engagement at Salem Church, May 3–4, 1863. In the fore part of April the Army of the Potomac, under Gen. Joseph Hooker, and the Army of Northern Virginia, Gen. Robert E. Lee commanding, confronted each other on opposite sides of the Rappahannock at Fredericksburg. Lee was so strongly entrenched on the south side of the river from Port Royal on the right to Banks' Ford on the left, a distance of 25 miles, that an attack on his front was impossible. Hooker decided to march his cavalry around Lee's left, destroy his communications with Richmond, compel him to evacuate Fredericksburg, at which time he proposed to fall on his flank and rear as he fell back. Gen. George Stoneman was ordered, on April 13, to ascend the Rappahannock with his 10,000 cavalry, cross it west of the Orange and Alexandria Railroad, attack Lee's cavalry wherever met, and cut off his line of retreat. Hooker was obliged to modify his plans when Stoneman found the streams impassable because of the heavy rains. He determined to force Lee to come out and fight on open ground of Hooker's own choosing.

Lee had, in and around Fredericksburg, exclusive of cavalry, about 60,000 men and 170 guns. The two divisions of Lafayette McLaws and Richard H. Anderson of Longstreet's corps, and Thomas J. (Stonewall) Jackson, with the divisions of Ambrose P. Hill and Daniel H. Hill, commanded by Robert E. Rodes; Isaac R. Trimble, commanded by Raleigh E. Colston and Jubal A. Early.

Hooker possessed, exclusive of 12,000 cavalry and 380 guns, about 118,000 men divided into seven corps: 1st, Gen. John F. Reynolds; 2d, Darius N. Couch; 3d, Daniel E. Sickles; 5th, George G. Meade; 6th, John Sedgwick; 11th, Oliver O. Howard; and 12th, Henry W. Slocum. Both armies were in excellent fighting condition.

On the 27th the 11th and 12th corps marched for Kelly's Ford, 25 miles up the Rappahannock, arriving on the 28th and, being joined by the 5th Corps, crossed the river, the first two marching for Germanna Ford on the Rapidan, the 5th Corps for Ely's Ford, lower down the same stream. Alfred Pleasanton's cavalry brigade accompanied the two columns. Some opposition was met at the fords, and at 2 P.M. of the 30th, after some sharp encounters with Stuart's cavalry, on the Germanna road, the three corps united at Chancellorsville, 11 miles west of Fredericksburg, and were joined the same day by two divisions of the 2d Corps, under Couch, which had crossed the Rappahannock at United States Ford, the 3d Corps also being near. The cavalry was thrown out on the roads toward Fredericksburg and Spottsylvania. Hooker had concentrated with great ability 71,000 men on Lee's left and joined them before night. William Mahone's and Posey's brigades of Anderson's Confederate division had been guarding United States Ford; the passage at Germanna Ford turned this position, and the two brigades fell back to Chancellorsville on the 29th, where Anderson had come up with Marcus J. White's brigade. Next morning Anderson fell back with the three brigades to near Tabernacle Church, four miles, and began to throw up works covering the roads converging at that point. These movements on Lee's left were covered by demonstrations on his right and front below Fredericksburg. They began as early as the 21st, and on the 29th Sedgwick, with the 1st, 3d, and 6th corps, moved to points two to four miles below town, threw pontoon bridges across the river and crossed troops to hold them. On the 30th he was ordered to demonstrate on Lee's right down the river, and the 3d Corps marched by the north bank of the river for Chancellorsville. Sedgwick's movements did not deceive Lee. On the afternoon of the 29th Stuart had informed him that heavy Union columns were marching for the Rapidan, and he ordered Anderson to march with Wright's brigade to Chancellorsville. When informed that Hooker had crossed the Rapidan he ordered McLaws, leaving William Barksdale's brigade on Marye's Heights, to march with three brigades at midnight of the 30th, and take position on Anderson's right. Jackson was ordered with three divisions to Chancellorsville, leaving Early's division with Barksdale's brigade—in all, about 8,500 men and 30 guns—to hold the lines at Fredericksburg against Sedgwick. McLaws arrived on Anderson's right about daylight, and was joined by two of Anderson's brigades from near Banks' Ford. Jackson marched at 3 o'clock on the morning of May 1, and came up to Anderson at Tabernacle Church at 8, suspended work on the entrenchments and, at 11 o'clock, ordered McLaws and Anderson forward on the two roads leading to Chancellorsville, his own three divisions following Anderson.

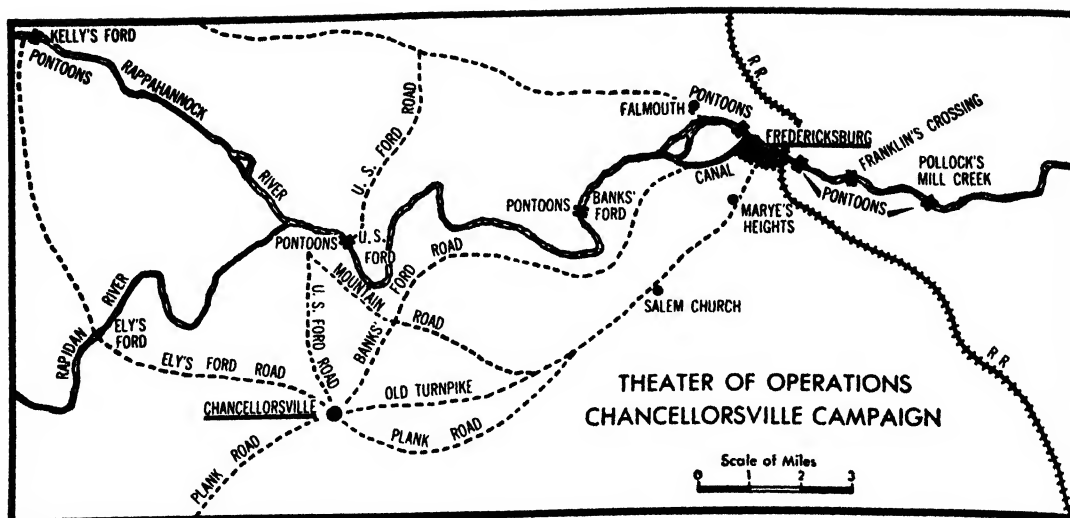

Three roads led from Chancellorsville to Fredericksburg, the most direct, the old turnpike, passing Salem Church. The second, the plank road, led south from Chancellorsville, then east, uniting with the turnpike beyond Tabernacle Church. Both these roads were covered by Anderson's works. The third road led northeastward, passed Banks' Ford, about six miles distant, and continued to Fredericksburg. It was 11 o'clock, May 1, when Meade pushed out two divisions on the Banks' Ford road and one, George Sykes', on the turnpike, under orders to be at

or near Banks' Ford at 2 P.M. At the same hour, 11 A.M., Slocum advanced on the plank road, to be at Tabernacle Church at noon. Hooker's intention being to get out of the Wilderness, uncover Banks' Ford, and form for battle in open, elevated country, his right at Tabernacle Church, his left covering Banks' Ford. Meade's left division had come in sight of Banks' Ford; Sykes, supported by Hancock's division, 2d Corps, had encountered McLaws and driven him back nearly to Anderson's works; Slocum, over two miles out, had met Jackson and was sharply skirmishing with him; and all was going well, when Hooker, impressed by the unexpected advance of the enemy, and fearing his own inability to get entirely out of the tangled forest onto open ground before being beaten in detail, ordered the columns back to Chancellorsville, thereby giving up the advantage of position practically gained, and losing the confidence of his corps commanders. Jackson and McLaws followed the retiring troops and felt out the lines with skirmishers, and McLaws got guns in position and cannonaded the left of the line. Hooker's line, as completed on the morning of May 2, extended

from the Rappahannock on the left to a point on the Germanna plank road fully $2\frac{1}{2}$ miles west of Chancellorsville. The 5th Corps and a division of the 2d Corps were well on the left, facing east, the right, in advance of Chancellor House. The 12th Corps was south of the plank road, its left less than one fourth of a mile in front of the Chancellor House, its right a mile southwest near Hazel Grove.

David B. Burney's division of the 3d Corps was on the right of the 12th, and the 11th continued the line from Dowdall's tavern westward beyond Talley's farm. The works held by the 3d, 12th, and 11th corps faced south, those of the 12th in the form of a bow, the plank road being the string of the bow; those of the 11th ran in a straight line generally just south of the road. For nearly the entire distance the line ran through an almost impenetrable forest of scrub oak and pine. There was a spacious clearing around the Chancellor House, where Hooker had his headquarters, and open ground around Dowdall's. A division of the 2d Corps and two of the 3d were in reserve. Pleasanton's cavalry was near Chancellor's House. On the evening of May 1, Lee had a conference with Jackson. To attack Hook-

er's 71,000 men, behind works, with 48,000. was certain to entail a terrible loss of life, and it was determined that Jackson, with nearly 30,000 men, infantry, cavalry, and artillery, should march across Hooker's front and assail his right flank and rear, Lee remaining with McLaws' and Anderson's 18,000 men to watch his left, demonstrate on it, and guard the roads to Fredericksburg. Jackson moved on the morning of the 2d with his accustomed celerity, and about 5:30 p.m. his head of column was on Hooker's right and rear, and he began to form line a scant mile from the right flank of the 11th Corps. His movement had been discovered and misunderstood. As early as 9 o'clock he was seen marching a mile or so to the south; information of the fact was sent to Slocum and Howard, and the instructions to both to strengthen their flanks. Hooker soon came to the conclusion that Lee was retreating, and about 1 p.m. Sickles, at his own request, was ordered to take two divisions of the 3d Corps, move out and attack, which he did, falling on Jackson's rear at Welford's Furnace, taking some prisoners.

Francis C. Barlow's brigade of the 11th Corps was sent to Sickles, and Pleasanton's cavalry joined him, but the forest was too dense for cavalry operations, and Pleasanton withdrew two of his regiments and battery to Hazel Grove. Williams' division of the 12th Corps was sent to form on Sickles' left, attack Anderson's left and roll him back on Chancellorsville. He was about to attack when Jackson fell on the flank of the 11th Corps and went back to his works. Lulled into security by reports that Jackson was retreating, no adequate provision was made against a flank attack, and the men were preparing supper when the storm broke. Jackson had formed his 26,000 infantry in three lines across the plank road, a mile on either side of it, artillery in the road, and at 5 o'clock gave the order to advance. Union skirmishers were quickly driven in, and, with a wild yell, the main Confederate line struck the right brigade of Charles Devens' division, flanked it, and, after a few rounds had been fired, it gave way, the enemy following. No troops in the world could stay such an attack. Some regiments made a heroic resistance and fought brilliantly, but in 30 minutes Devens' division of 4,000 men was routed, and the Confederates were

able to advance upon Carl Schurz's division which had changed front. Schurz held ground about 20 minutes, and then fell back upon Buschbeck's brigade, east of Dowdall's. Here Schurz rallied some of his men. Buschbeck stood three quarters of an hour, and it was after 7 o'clock when, attacked in front and flank, he fell back in good order to Fairview, where 40 guns of the 11th and 12th corps were being massed on high ground in his rear. Howard's corps had been driven two miles in less than two hours, losing nearly 1,500 killed and wounded, and 1,000 prisoners. The force of Jackson's attack had spent itself; his two leading divisions—Rodes' and Colston's—had become inextricably mixed; the men were tired and hungry, and Jackson suspended their further advance and ordered A. P. Hill to relieve them.

Meanwhile, Hooker had sent Hiram G. Berry's division of the 3d Corps and Alexander Hays' brigade of the 2d Corps to the west edge of the open field north of the road; on Berry's right were some of Schurz's regiments; and Williams, desisting from his attack on Anderson, regained part of his works and formed south of the road on Berry's left, Buschbeck in his rear. This covered the road at a distance of a little over a half mile west of Chancellor's House. Sickles, when informed of Howard's disaster, fell back from Welford Furnace to Hazel Grove and formed on Pleasanton's left. Barlow drew up in Pleasanton's rear, all close to Williams' left and front. The two Confederate lines fell back to the open ground around Dowdall's, to re-form, and A. P. Hill was brought up and his leading brigade pushed along the plank road beyond the intersection of a road leading left to White House, and United States Ford, the road to be taken by Hill to cut off Hooker's retreat. While Jackson was reconnoitering on this road, beyond his main line, skirmishing began between the opposing pickets in the woods, and as Jackson, with his staff and orderlies, was riding back, the mounted body was mistaken for Union cavalry and fired into, Jackson (about 9:20 p.m.) was wounded in three places, both arms being shattered. Nearly the entire escort were also killed or wounded. Jackson died May 10.

At the sound of the firing in the woods the

Union guns on Fairview opened a furious fire down the plank road, causing some confusion to the Confederate column on it. During this fire A. P. Hill, next in command, was wounded; the intended advance was suspended, and Gen. J. E. B. Stuart was sent for to take command. During the night and early morning some changes were made in the Union line by which the approaches on the right to the United States Ford were covered by Reynolds' corps and part of Meade's, and the 11th Corps took position on the extreme left vacated by Meade. At 9 P.M. Hooker, not knowing that Sedgwick's entire corps was at Fredericksburg, ordered him to cross from Falmouth and march up the south side of the river to Chancellorsville and attack Lee's rear at daylight, May 3, while he attacked in front. Pleasanton and Sickles were ordered to fall back from Hazel Grove at dawn. Pleasanton marched back at 4 o'clock, and Sickles was following when his rear was caught by the oncoming Confederate line. Stuart, who had assumed command of Jackson's corps, advanced at 5 o'clock, May 3, with great impetuosity, his right attacking Sickles as his rear brigade was retreating from Hazel Grove. The brigade was soon driven, four guns were captured and Stuart swept on. Thirty Confederate guns were put in position at Hazel Grove which swept the open ground of Fairview and poured an enfilading fire on the right of John W. Geary's division of the 12th Corps which was fighting Anderson, and at the same time Geary's left was being pounded by McLaws' guns. The battle now became fierce along the entire line of the 2d, 3d, and 12th corps. On the right Stuart's men fought William H. French's division of the 2d Corps and the three divisions of the 3d Corps, taking, losing, and retaking the Union works. Williams was fighting Stuart's right, Geary was desperately engaging Anderson, and on his left, covering Fredericksburg road, Hancock's division of the 2d Corps was resisting the fierce attacks of McLaws. Stuart gradually gained ground and united his right with Anderson's left near Hazel Grove. The Union ammunition began to fail, and finally, about 9 o'clock, French, of the 2d Corps, the 3d Corps, and Williams' division of the 12th, after frightful losses, began to fall back, and the Confederates gained the west of the Chancellor plateau and swept it with artillery. A cannon shot struck a pillar of the Chancellor House against which Hooker was leaning. He was knocked down and stunned, and Couch, who was second in command, was instructed by Hooker to withdraw to a position, already selected, about three fourths of a mile north of the Chancellor House, and covering United States Ford. The right and center, closely pressed, fought their way back; Geary, attacked in front, right flank, and rear, followed; Winfield S. Hancock followed Geary. Before noon the troops were in a new position, and here the Battle of Chancellorsville may properly be said to have ended. Before Lee had completed his preparations to renew his attack, he heard of the capture of Marye's Heights and Fredericksburg, and the advance of Sedgwick. Suspending further operations against Hooker he sent McLaws' division to oppose Sedgwick.

When Sedgwick received Hooker's order of 9 P.M., May 2, to cross the river at Fredericksburg, he had already done so, and was three miles below the town. He had 14 miles to march

before he could reach Chancellorsville, and an enemy barred the way. He had about 23,000 men. His three divisions were commanded by Gens. John Newton, William T. H. Brooks, and Albion P. Howe. Brooks was left below Fredericksburg, and Newton led the advance on the town. The advance was slow and difficult, and as dawn came Marye's Heights was seen to be in the hands of the enemy. John Gibbon crossed the river at Falmouth and reported to Sedgwick with his division and, under cover of a demonstration by Newton, advanced on the right to turn the position, but was stopped by the canal and a concentrated fire of artillery. He found also that Hays' brigade of Early's division and Cadmus M. Wilcox's of Anderson's were in his front, and he was obliged to fall back. On the other flank Howe's division failed to make an impression. Nothing remained but to assault the heights and storming columns were formed, Howe forming three on the left and Newton two of two regiments each, strongly supported. These were launched against the Confederate position and were bloodily repulsed by Barksdale's brigade. The assault was renewed and Marye's Heights carried about 11 o'clock, with a loss to Sedgwick of nearly 1,000 killed, wounded and missing in a very few minutes. He took 15 guns and nearly 1,000 prisoners. Here a delay occurred to get Brooks' division up, which was to take the advance, and it was 3 o'clock before Sedgwick marched for Chancellorsville, leaving Gibbon to hold the town and cover the bridges there. His march was impeded by Wilcox, who had regained the road in his front and made a stand half a mile in advance of Salem Church, where McLaws had now come up and formed across the road. Brooks' division advanced and Wilcox fell back to the church, Brooks closely following, and a desperate encounter raged around the church, in which at first Brooks, supported by Newton, was successful, but was finally compelled to fall back after losing 1,500 men. Dispositions were made to renew the struggle, but night came and both sides slept on their arms. Early, who had concentrated his command at Cox's, on the telegraph road, south of Fredericksburg, had Lee's permission to attack Marye's Heights and Sedgwick's rear at daylight. He was joined by Barksdale and, as Marye's Heights were held by only a small Union force, his attack succeeded. Leaving Barksdale to hold the heights and prevent an advance of Gibbon, who was in the town, Early moved toward Salem Church and asked McLaws to cooperate with him.

Meanwhile Lee, retaining only Jackson's three depleted divisions to confront Hooker at Chancellorsville, led Anderson to unite with McLaws and Early, and drive Sedgwick across the Rappahannock, the three divisions aggregating about 21,000 men. Anderson arrived about noon of the 4th and took position between McLaws and Early. Sedgwick was now hemmed in on three sides, his line in shape of a horseshoe, both flanks on the river covering Banks' Ford. The line was five or six miles in length, Newton, on the right, facing McLaws on the west; Brooks, in the center, facing south, confronting Anderson, and Howe, on the left, facing east, opposing Early. Skirmishing was kept up during the day, and at 6 o'clock, Lee, after reconnoitering the position, ordered an attack to break the center. Newton was not seriously attacked but Howe and Brooks were assailed with great spirit, Early,

falling upon the former and endeavoring to turn his left, in which he did not succeed, two of his brigades being repulsed and thrown into confusion by Howe's artillery. An attack on Howe's right and Brooks' left was also repulsed. The Confederates continued the contest until darkness put an end to it. Sedgwick then withdrew from the field to Banks' Ford, where he was covered by 34 guns on the north side of the river, but he had lost so heavily and was hemmed in so closely that, with Hooker's approval, he crossed the river during the night, taking with him nine captured guns and about 1,400 prisoners. His loss, since crossing the river on the 2d, had been 3,200 killed and wounded and 1,500 captured. During the night Gibbon recrossed the river to Falmouth and, on the morning of the 5th, Lee was again in full possession of the south side of the river below Chancellorsville. Early was left to hold Fredericksburg, and Lee marched back with McLaws and Anderson to renew the battle with Hooker. A heavy storm came up, converting dry ravines into torrents and the soil to deep mire, and the attack was deferred until next morning. When day came Hooker had recrossed the river at United States Ford, and the Army of the Potomac marched to its old camp, and Lee returned to his old position at Fredericksburg.

The Union loss at Chancellorsville was 1,082 killed, 6,849 wounded and 4,214 missing. Including the losses at Fredericksburg, Marye's Heights and Salem Church, the Union loss in the entire campaign, April 27 to May 5, was 1,606 killed, 9,762 wounded and 5,919 missing; an aggregate of 17,287. The Confederate loss during the campaign was 1,665 killed, 9,081 wounded and 2,018 captured; an aggregate of 12,764.

CHANCERY, formerly the highest court of justice in England, now consolidated with the other superior courts in the Supreme Court of Judicature.

The Court of Chancery obtained its name from being under the jurisdiction of the lord chancellor and its purpose was never more succinctly expressed than in Cowel and Jacob's *Law Dictionary*: "All the other justices in the Kingdom are tied to the law, but the Chancellor hath the King's absolute power to moderate the written law, govern his judgment by the law of nature and conscience, and ordering all things *juxta æquum et bonum*. . . . He is not limited by the written law, but by conscience and equity, according to the circumstances of the matter." And in the words of King James I, "When the rigour of the law in many cases will undo a man, then the Chancery tempers the law with equity, and so mixes mercy with justice, as it preserves a man from destruction." The jurisdiction of the court was therefore wide; and between it and the common lawyers a long struggle ensued. Its jurisdiction was inoperative

in ordinary common law cases, or in civil cases in which the common law courts could render adequate justice. The great objection of the common law practitioners was that the very extensive powers of the chancellor's court were exercised, not according to fixed rules of law, but at the discretion of the chancellor. In course of time, however, under a succession of able chancellors, the body of law administered by it became quite as fixed as the common law. Thus there came into existence the curious anomaly of two coordinate sets of tribunals adjudicating on the same matters on conflicting principles. It was thus quite possible for a suitor to win in the Court of Chancery who had not the smallest chance of prevailing in the common law courts. In the caustic words of Lord Chancellor Richard Bethell, 1st baron Westbury, one tribunal was set up to do injustice and another to stop it. The distinctive functions of the Court of Chancery remained until the passing of the Judicature Acts of 1873 and 1875. (See below.) The Court of Chancery embraced six superior courts called high courts of chancery and numerous inferior courts. The superior courts were the Court of the Lord High Chancellor, the Court of the Master of the Rolls; the Court of Appeal in Chancery, constituted by the lord chancellor sitting alone with either of the two lords justices in appeal or by the two lords justices sitting together apart from the lord chancellor; and the courts of the three vice-chancellors. The ordinary legal jurisdiction of chancery embraced the issuing of writs for a new Parliament; of pleas of *scire facias* to repeal letters patent, and of all original writs. There was also a jurisdiction acquired by statute or special delegation in issuing writs of habeas corpus and inquiring into charitable uses. There were numerous other powers conferred by act of Parliament, and the lord chancellor, together with the lords justices of appeal, had exclusive authority over the persons and property of idiots and lunatics. Appeals in bankruptcy were heard by the Court of Appeal in Chancery. The sittings and business of this court of appeal were regulated by the lord chancellor.

The procedure of the Court of Chancery at one time, by reason of its traditions and forms, commonly known as red tape, became so cumbersome as partially to defeat its own ostensible aims and rendered reform imperative. Charles Dickens made a determined attack upon the delays of chancery practice in his interesting novel, *Bleak House* (1853), and subsequent changes have been commonly attributed to his influence.

The English Court of Chancery is now a division of the High Court of Justice, which is itself one of the two departments of the Supreme Court of Judicature in which are united all the higher courts of justice in England, exclusive of the appellate jurisdiction of the House of Lords and the privy council. The present judges of chancery as a division of the High Court of Justice are the lord chancellor, who presides over the division, and six justices. According to the provisions of the act by which the Supreme Court of Judicature was established, the distribution of business, both as to its commencement and its transfer, was made subject to rules of court and orders of transfer. By the operation of these provisions chancery, like the other divisions of the court to which

it now belongs, was gradually to cease to be a separate department; but in the meanwhile, subject to these rules and orders, certain causes and matters were assigned to chancery until these provisions should take their full effect. These are enumerated in the Supreme Court of Judicature Act (36 & 37 Vict. c. 66, § 34), and are (1) all causes and matters pending in the High Court of Chancery at the commencement of the act (finally fixed for Nov. 1, 1875); (2) all causes and matters to be commenced after the commencement of the act under any act of Parliament by which exclusive jurisdiction in respect to such causes or matters has been given to the Court of Chancery, or to any judges or judge thereof, except appeals from county courts; (3) administration of the estates of deceased persons; partnerships; mortgages; raising of portions or other charges on land; sale and distribution of the proceeds of property subject to any lien or charge; trusts, charitable or private; rectification or setting aside or cancellation of deeds or other written instruments; performance of contracts between vendors and purchasers of real estates, including contracts for leases; partition and sale of real estate; wardship of infants and the care of infants' estates. Chancery, as a division of the High Court of Justice, has no exclusive right to the administration of equity, the act already mentioned making provision under certain rules for the concurrent administration of law and equity in all the divisions of the Supreme Court of Judicature. The Court of Appeal in Chancery no longer exists and its functions are transferred to the Court of Appeal, which in the new Supreme Court of Judicature is the complementary department of the High Court of Justice. The affairs of lunatics are still under the supervision of the old chancellor. See also EQUITY.

In the United States the general tendency has been likewise to abolish courts of chancery as separate departments, and equity jurisdiction is generally conferred on the courts of law. Delaware, New Jersey and Tennessee are among the few states that still retain the former practice.

In the Catholic Church the chancery denotes (1) the office in a diocese whence come those documents necessary for the exercise of parochial power; (2) the office in Rome which drafts and expedites the bulls or briefs by which the mind of the pope is made known to Christendom or to particular suitors.

CHANCRE. See SYPHILIS.

CHANCROID, shǎng'kroid, a contagious venereal disease, characterized by the presence of one or more suppurating ulcers, located chiefly in the genital region of either sex. These are due to infection by microorganisms lurking in dirty skins, and are not syphilitic in origin, although often coexisting with true syphilitic lesions. Even though this is the case, the two can be distinguished, since the chancroid is soft and not indurated. Chancroid is essentially a filth disease, although venereal, and arises from personal uncleanness. The specific organism is the *Hemophilus ducreyi*. Chancroid develops usually within 24 to 48 hours after infection, a much shorter interval than in syphilis. At first a small papule surrounded by a reddish areola appears, which soon spreads to become an ulcer. These ulcers are extremely painful, and may be followed by enlargement and suppuration of the

glands of the groin (bubo). The chancroid persists as a rule from three to six weeks, and is often extremely resistant to treatment. If the complication of suppurating inguinal glands occurs, convalescence may be protracted and drainage may be required. In some cases infection of other areas of sound skin may take place.

HAROLD WELLINGTON JONES, M.D.

CHANDA, chān'dā, town in the district of Chanda in the Nagpur division of the Central Provinces, Indian Union, 85 miles south of the town of Nagpur. It was the old capital of the ancient Gond dynasty. It is surrounded by a stone wall five and a half miles in circuit, from 15 to 20 feet high, 10 feet thick and flanked with rough towers large enough for the heaviest guns; inside which are cultivated fields and detached villages, while there are also suburban quarters outside. Without the walls is a large water tank constructed under Gond rule and a collection of ancient statuary known as Rayappā's idols, the largest of which is 26 by 18 by 3 feet. Chanda is the commercial center of the district with manufactures of silk, cotton, dyestuffs, slippers, bamboo work and gold and silver work. It has numerous schools and a mission station. The district contains considerable iron and coal deposits. Pop. (1941) 35,730; the district has an area of 10,156 square miles and a population of (1941) 873,284.

CHANDAUSI, chūn-dou'sē, a town in the western section of the United Provinces, Indian Union, 95 miles east of Delhi. It is an important rail and trade center. Pop. (1941) 26,768.

CHANDELEUR, shān-dē-lūr', **ISLANDS**, a group of about 15 small islands in the Gulf of Mexico about 25 miles off the east coast of Louisiana, from which they are separated by Chandeleur Sound. There is a lighthouse on the northern end of the northernmost island which is in latitude 30° 2' north and longitude 88° 52' west.

CHANDELIER. An apparatus suspended from the ceiling or vault and supporting two or more lighting units. Usually, in modern times,

Fig. 1.--(1) Roman Christian Lucerna pensilis for four wicks (from the Catacombs). (2) Corona style Chandelier (from an old MS.). (3) German church Chandelier of the Middle Ages.

the lights are supported on arms or branches radiating from a central shaft. The chandelier may be said to have originated in the ancient suspended oil lamp (*lychnus*) of several wicks (*polymixos*) used by the Romans. (See Fig. 1). By the 4th century A.D. the Catholic Church began to use *coronae*, *phari*,

pharicanthari, circuli luminum, polycandelae, etc., carrying a multitude of candles (Pope Adrian presented St. Peter's, Rome, with one carrying 1,370 candles in the 8th century). These were all terms for the *corona lucis* (see CORONA), or crown light. Great and beautiful examples of these elaborate crown lights are still in existence in the "heavenly Jerusalem" design, with their small towers or "tabernacles" or "gates" for the Apostles. That presented by Frederick Barbarossa to the minster at Aix-la-Chapelle is 13 feet in diameter. (See Fig. 2.) Another is in the Hildesheim Cathedral (circa 1050), 20 feet in diameter with 72 candle holders.

Most of the elaborate crown lights were constructed in the 11th and 12th centuries, and while many carried candles, others were for oil lamps. Their construction was, for the most part, of metal (copper, iron, silver, even gold) and ornamented with enamels, etc.; some were of wood. In the 13th century elaborate forged

deliers at this time which are yet much admired. To this century belongs the famous historic "Galiëo" chandelier in the Cathedral of Pisa, a magnificent work of bronze of the Italian Renaissance, whose swinging is said to have led to the pendulum in horology.

In the 17th century a few wooden chandeliers were still produced, but with artistic carved decoration—most of them were constructed for temporary (festivals, etc.) use. Under Louis XIII Dutch copper chandeliers became popular. This style had a central shaft composed of a number of balls relieved by balustre forms. A common device was to have the chandelier surmounted by a royal crown, ducal or other coronet. Very elaborate chandeliers were produced in this century in wrought iron, bronze and copper (Flanders was doing very fine work in copper castings). Silver was used to some extent, also rock crystal was becoming quite the vogue; but the former

FIG. 2.—The great 13th century Corona Chandelier at Aix-la-Chapelle Minster. Details: left, section of railing; right, style of tower decoration.

ironwork was in great vogue, therefore chandeliers were fashioned in this manner. In the 14th century chandeliers began to take on a star or radiation form with six to eight branches supporting a number of candles or lamps. These were mostly of bronze. In this period a species of trophy device in chandeliers took form in Germany, made up of the horns of the animals of the chase (stag, elk, elephant, etc.). This fashion remained popular till the 18th century. In the 15th century wooden crosses acted as chandeliers frequently. Oak was much favored, and, while many were quite plain, others, for church use, had elaborately carved centerpieces from which radiated handsomely decorated curved arms of forged iron supporting candle sockets; others were entirely of bronze or copper, a few of silver. The plain crown light still persisted.

The 16th century retained much of the radiate style of the preceding century but rock-crystal decoration (which had been practiced in a modest way since the 13th century) appears (from documentary evidence) to have become more general. Flanders produced lovely chan-

deliers at this time which are yet much admired. The crystal ornament was becoming a part in the establishments of the wealthy.

In the 18th century the thorough combustion (sootless) of oil was becoming effective (Argand, Lange, Quinquet inventions), and we have suspended lamps largely replacing candles in chandeliers. Under Louis XV and Louis XVI were constructed for lay use more chandeliers of great importance than ever before, the church having had the very large and elaborate pieces. The furnishing of civic homes with luxurious decoration was a new growth, and, by the second half of the 18th century, practically all chandeliers had crystal ornament. Every chandelier by this time had arms or branches; the "console" or reclining *u* was the form prevalent. A common style of crystal decoration consisted of interlacing strings of faceted crystal beads—often so elaborate as to be cumbersome. Ordinary glass sufficed usually, but rock crystal was favored by the wealthy. The chandelier, in some form, was now common property among

all classes of city dwellers, except the very poorest. In chandeliers de luxe we find porcelain (Dresden and Sèvres) flowers figuring as ornament, and soon the usage of these fictile

FIG. 3.—Horizontal plan (bird's-eye view) of Aix-la-Chapelle Corona Chandelier.

flowers became so common that porcelain flower making became a distinct Paris industry. Some chandeliers of the Louis XVI period had

FIG. 4.—A fine Louis XIV (17th and early 18th centuries) Rock Crystal 8-light chandelier.

their faceted beads made of stass, some of polished steel.

During the early years of the 19th century but one style prevailed in the construction of chandeliers, bronze-gilt frames so swarming with crystal decoration as to make the chandelier body a mere accessory hidden in garlands of crystal beads. Immense, gorgeous constructions were

made for use in the theaters, and so forth, the most noted being that of the Grand Opera House, Paris, by Jean Louis Charles Garnier. With the introduction of hydrogen gas for lighting purpose no great transformations occurred in the forms used for chandelier (often termed *gasolier*) construction, pipes taking the place of bar metal and gas nipples displacing the old candle pricket or the later sockets. The designer had a wider field to work in when illumination by electricity was introduced. Strikingly artistic forms were evolved in the *electrolier*, some reverting to the classic Greco-Roman *lychnus*, others showing modern originality.

CLEMENT W. COUMBE.

CHANDERNAGOR, chūn-dēr-nà-gōr', or **CHANDARNAGAR**, chūn-dēr-nūg'ēr, city, India, on the Hooghly River, 21 miles north of Calcutta. With adjoining territory (the total area being 4 square miles), it was a settlement of French India until 1950, when France yielded it to India after a referendum of June 19, 1949, had revealed the inhabitants' preference for Indian rule. The only manufacture is cotton cloth. Established as a trading center by the French East India Company in 1676, it was ceded to France in 1688 by Emperor Aurangzeb. Chandernagor was captured by the British in 1757 but restored in 1763. Again seized by the British in 1794, they once again yielded it to France in 1816. The treaty of cession to India was ratified June 9, 1952. Pop. (1948) 44,786.

CHANDIGARH, chūn'dē-gūr, city, India, capital of the Punjab, near the Ghaggar River, on the Delhi Kalka rail line, 25 miles north-northwest of Ambala. India's youngest city, the Punjab government announced plans for construction in 1948 and engaged Le Corbusier (Charles Édouard Jeanneret), the famous Swiss architect, as its designer. Construction was started on a 15-square mile site in 1950; it was formally inaugurated as the state capital on Oct. 7, 1953. The town is dominated by the capitol buildings—the High Court, Legislative Chamber, Secretariat, and the Raj Bhavan. It incorporates the most modern ideas of town planning and many unique architectural features. A resident population of 150,000 is envisioned by 1958. Pop. (1954) 10,000.

CHANDLER, Abiel, American merchant: b. Concord, N. H., 1778; d. Walpole, March 22, 1851. He was graduated at Harvard College in 1806, and was for many years a merchant in Boston. He died a widower, without children, and devised \$50,000 to Dartmouth College. The Chandler School of Science at Dartmouth was established in 1851 in pursuance of this bequest.

CHANDLER, Asa Crawford, American biologist: b. Newark, N. J., Feb. 19, 1891. A graduate of Cornell (B.A. 1911), he received his M.Sc. and Ph.D. degrees from the University of California (1912 and 1914). After teaching in American universities he engaged in hookworm research at the School of Tropical Medicine, Calcutta, for three years. Returning to the United States in 1927 he was appointed professor of biology at Rice Institute, Houston, Texas. From 1942 to 1947 he also was special consultant to the United States Public Health Service. His works include *Hookworm Disease* (1929) and *Introduction to Parasitology*, 8th ed. (1949).

CHANDLER, Charles Frederick, American chemist: b. Lancaster, Mass., Dec. 6, 1836; d. New York, Aug. 25, 1925. He studied at the Lawrence Scientific School of Harvard, and in Germany at Göttingen and Berlin. From 1857 to 1864 he was professor of chemistry at Union College, Schenectady, N. Y., then accepting a like chair at Columbia University. There he collaborated with Thomas Egleston (1832-1900) in founding the School of Mines, the first of its type to be established in the United States. Chandler continued at Columbia as professor of chemistry until 1910, serving also as dean during 1864-1897 and as professor of chemistry at the Columbia College of Physicians and Surgeons from 1876 to 1897. In 1866 he was appointed chemist of the New York City Board of Health. He was made president of the board in 1873, an office which he filled until 1883. Regarded as an authority on water supply and sanitation, he campaigned for compulsory vaccination and enforcement of pure food laws and against the adulteration of milk. The New York State Board of Health was established largely on account of his efforts, and he was one of the founders of the American Chemical Society, which he served for two terms as president.

CHANDLER, Francis Ward, American architect: b. Boston, Sept. 30, 1844; d. North Haven, Me., Sept. 8, 1926. He was graduated at the Lancaster Academy in 1861, and in the American Civil War he served with the 53d Massachusetts Volunteers. Taking up the study of architecture, he worked with Ware and Van Brunt, Boston, during 1864-1867. He spent 1867-1869 in Paris and during 1869-1870 he was assistant in the architectural department of the Massachusetts Institute of Technology. In 1871 he became assistant architect in the Treasury Department, Washington. From 1874 to 1888 he was a partner of E. C. Cabot, Boston, and in 1888 he was appointed professor of architecture in the Massachusetts Institute of Technology; he became professor emeritus in 1911. He published *Construction Details* (1892); *Notes on Limes, Cements, Mortars, and Concretes* (1892); and edited *Municipal Architecture in Boston* (1898) and many articles in the *Technology Quarterly*.

CHANDLER, Frank Wadleigh, American educator: b. Brooklyn, N. Y., June 16, 1873; d. Prouts Neck, Me., June 13, 1947. He was graduated from Brooklyn Polytechnic Institute in 1894, and from 1895 to 1899 he studied at Columbia University, at Oxford, in London, and Paris. From 1899 to 1910 he was professor of literature and history at Brooklyn Polytechnic Institute, and from 1901 to 1904 he lectured at Columbia on comparative literature. He served as professor of English and comparative literature at the University of Cincinnati from 1910 until his retirement in 1943; during 1913-1928 he was also dean of the university's college of liberal arts. For 19 consecutive summer sessions he also taught comparative literature at Columbia. His writings included *The Literature of Roquery* (1907) and *Modern Continental Playwrights* (1931).

CHANDLER, Richard, English classical antiquary: b. Elson, Hampshire, 1738; d. Tilehurst, Berkshire, Feb. 9, 1810. He was educated at Winchester, and at Queen's and Magdalen colleges, Oxford. His first important work was

Marmora Oxoniensia (1763), an elaborate description of the Arundel marbles. He afterward traveled through Greece and Asia Minor, at the expense of the Dilettanti Society, to examine and describe the antiquities. The materials collected were given to the world in the following publications: *Ionian Antiquities* (1769); *Ancient Inscriptions* (1774); *Travels in Asia Minor* (1775); and *Travels in Greece* (1776). He was an Anglican clergyman, and at his death was rector of Tilehurst, near Reading.

CHANDLER, Seth Carlo, American astronomer: b. Boston, Mass., Sept. 17, 1846; d. Wellesley, Mass., Dec. 31, 1913. From 1864 to 1870 he was on the staff of the United States Coast Survey, and he was associated with Harvard Observatory from 1881 to 1885. The Astronomical Society of London awarded him its gold medal in 1896 for his determination of the laws of variations of latitude or movements of the earth's pole, and his researches on variable stars. From 1896 he edited the *Astronomical Journal*. He made important investigations and observations of the phenomena of variable stars, the computation of comet orbits, and devised a system of astronomical code telegrams for the announcement of astronomical discoveries. He also invented the almucantar, and published a very complete treatise on the method of its use.

CHANDLER, William Eaton, American politician: b. Concord, N. H., Dec. 28, 1835; d. there, Nov. 30, 1917. In 1855 he graduated at Harvard Law School. He entered the New Hampshire legislature in 1862, and during 1863-1864 served as speaker. During 1865-1867 he was assistant secretary of the United States Treasury. From 1882 until 1885 he served as secretary of the navy; and he was a United States senator from 1887 to 1901. He served during 1901 as president of the Spanish Treaty Claims Commission.

CHANDLER, Zachariah, American merchant and statesman: b. Bedford, N. H., Dec. 10, 1813; d. Chicago, Ill., Nov. 1, 1879. He received a common school education, and early in life went to Detroit, where he engaged in the dry goods business; his energy and ability soon brought success and put him in possession of a handsome fortune. He was mayor of Detroit in 1851, and defeated Whig candidate for governor of Michigan in 1852, and an active organizer of the Republican Party in 1854. In January 1857 he was elected to the United States Senate to succeed Gen. Lewis Cass. The same energy and ability which had made him successful in business, he now applied to the organization of the Republican Party, and he was soon recognized as one of the most formidable opponents of all plans in favor of slavery. He opposed the admission of Kansas under the Lecompton Constitution (q.v.) in 1858, and he was the author of the famous "blood letter," in which he said "without a little blood-letting, this Union will not, in my estimation, be worth a rush." Though a friend of Lincoln, he was more radical than the latter, and often differed from him in matters of public policy. He was reelected to the senate in 1863 and served until 1875, when he became secretary of the interior in the administration of President Ulysses S. Grant, an office he occupied until 1877. Again elected to the Senate in 1879, he led the attacks on Jefferson Davis.

CHANDOS, shǎn'dōs, titles in the English peerage borne by members of the Brydges family.

SIR JOHN BRYDGES (1490?-1556), 1st Baron Chandos of Sudeley descended through his mother from Sir John Chandos, was a supporter of Edward VI and Mary, and during 1553-1554 was lieutenant of the Tower of London. There he had custody of Lady Jane Grey and of Sir Thomas Wyatt (whose rebellion he had helped suppress). He was created 1st Baron Chandos of Sudeley in 1554.

JAMES BRYDGES, 8TH BARON CHANDOS (1673-1744), was paymaster general of the forces abroad during the War of the Spanish Succession (1705-1713). In 1714 he was created earl of Carnarvon; and in 1719 he became marquis of Carnarvon and duke of Chandos. He was a patron of George Frederick Handel who spent two years at Canons, Baron Chandos's magnificent home near Edgware, Middlesex, there composing the oratorio *Esther* (1720).

CHANDOS, **SIR JOHN**, English soldier: d. near Poitiers, France, Jan. 1, 1370. He was descended from Robert de Chandos, who came from Normandy with William the Conqueror in 1066. The earliest military records about John Chandos state that he was at the siege of Cambrai in 1337, at Crécy in 1346, and Poitiers in 1356, when he rescued his friend, the Black Prince, on the battlefield. He was soon afterward appointed "regent and lieutenant" of the king of England in France, and vice chamberlain of the royal household. In 1364 he commanded the English forces against Charles de Blois; the latter was killed at the Battle of Auray and the redoubtable Bertrand du Guesclin fell a prisoner to Chandos. In 1367 the Black Prince induced him to join a military expedition across the Pyrenees into Spain against Henry of Trastámara, who was aided by du Guesclin. In the ensuing battle at Navarrete, Chandos gained the victory and again captured du Guesclin. Retiring in 1368, Chandos was again called to arms against the French in 1369. He was mortally wounded in an engagement at the bridge of Lussac and died the following day. One of the original Knights of the Garter, he was esteemed at a gallant, chivalrous warrior.

CHANDRAGUPTA or **CHANDRAGUPTA MAURYA**, chūn-drā-gōp'tā mā'-ōor-yā (known in Greek as SANDROCOTTUS or SANDRACOTTUS), Indian ruler, first king of Magadha of the Maurya dynasty: d. 286? B.C. While in exile during his youth he made the acquaintance of Alexander the Great. Leading a revolutionary movement against the regime in Magadha, he established the Maurya dynasty and destroyed the Macedonian garrisons left in India by Alexander. He created an empire which extended right across northern India and northward as far as Afghanistan. In 305 B.C. he defeated Seleucus I (Nicator) in the Punjab, compelling him to surrender all claims to that and other Indian territories. An account of the court of Chandragupta was written by Megasthenes, the Greek historian, who was sent to it as ambassador by Seleucus in 302 B.C.

CHANEY, chā'nī, Lon, American motion picture actor: b. Colorado Springs, Colo., April 1, 1883; d. Los Angeles, Calif., Aug. 26, 1930. The son of deaf-mute parents, Lon Chaney undoubtedly owed much of his mastery of pantomime

to the fact that in childhood he necessarily communicated with his parents by gestures and facial expression. He left school before attaining the fifth grade to become a tourist guide on Pikes Peak. His first theater job was as property boy; later he became a stage hand. With his older brother John, a theater manager, he wrote *The Little Tycoon*, the play in which he made his stage debut. This was followed by performances in Gilbert and Sullivan operas. In Chicago he found stage employment as a comedian and song and dance man. He then joined a vaudeville troupe with which he went to California. His first experience in the movies was as an extra, after which he directed seven Western pictures. Returning to the screen, he played the villain in *Hell Morgan's Girl* (1917). His first outstanding characterization was the frog in *The Miracle Man* (1919). Other pictures in which he scored great successes included *The Hunchback of Notre Dame* (1923); *Road to Mandalay* (1926); *Mr. Wu* (1927); and *Laugh, Clown, Laugh* (1928). His portrayals of characters warped by a psychological or physical abnormality were masterly.

CHANG AND ENG. See SIAMESE TWINS.

CHANG TSO-LIN, jǎng' tsō'lin', Chinese military leader: b. Liaoning Province, 1876; d. Mukden, June 4, 1928. A man of lowly origin, in 1904 he emerged from obscurity as leader of a band of Manchurian bandits. He joined the Chinese Army in 1905, and by 1911 he was military governor of Fengtien. From 1918 he was in autocratic control of Manchuria, where he extended his influence into numerous civil activities. He made several attempts to establish a stable national government at Peking (Peiping), and in 1927 formed a Cabinet of his adherents there, with himself as president with the style of generalissimo. With the approach of the Southern Nationalists he left the city, and he was killed en route to Mukden when his train was bombed.

CHANGA, a species of mole cricket (*Scapteriscus didactylus*). See MOLE CRICKET.

CHANGARNIER, shān-gār-nyā', Nicolas Anne Théodule, French army officer: b. Autun, April 26, 1793; d. Versailles, Feb. 14, 1877. He entered the army as lieutenant in 1815, and in 1830 he was sent to Algeria, there serving with distinction for 18 years. Shortly after being appointed governor of Algeria in 1848 he was recalled to France to assume command of the National Guard and troops in Paris. Although he suppressed the radical elements he subsequently disagreed with the policy of Louis Napoleon, and at the coup d'état in December 1851 he was arrested. In January 1852 he was banished from France, remaining in exile until after the amnesty in 1859. With outbreak of the Franco-Prussian War he offered his services to Napoleon III. He was serving in Metz under Marshal Bazaine when that city capitulated on Oct. 27, 1870, becoming a prisoner of war. In 1871 he was elected a member of the National Assembly, serving until 1875, when he became a senator for life.

CHANGCHUN, chāng'chōn' (Japanese official name HSINKING, shin'jing'), city, Manchuria, capital of Kirin Province, on the railroad

165 miles north-northeast of Mukden. It is an important railroad junction. From the city are shipped large quantities of soybeans cultivated in the fertile valley of the Sungari River. Migration of Chinese farmers from the Shantung Province late in the 18th century caused Changchun to expand from a small village to a large town, and in 1932 it was chosen by the Japanese as the capital of its puppet state of Manchukuo. On Aug. 22, 1945, as World War II was closing, Russian paratroopers captured the city, and during the ensuing two years it was frequently the scene of conflict in the Chinese civil war. Pop. (est. 1945) 787,778.

CHANGE OF FUNCTION. During the metamorphosis of insects, Crustacea, and other animals, organs at first adapted for certain uses become, with change of conditions of life, media, and consequently of habits, adapted to quite different uses or functions. Thus in the young larva (nauplius) of many of the lower Crustacea, the three pairs of head appendages are formed for swimming; the first two pairs afterward change into the two pairs of antennae, the third pair becoming the jaws of the adult. In the tadpole, which lives on dead leaves or animal matter, the intestine is very long and coiled, but in after life, when the frog feeds on living insects, it is very much changed in form, being much shorter. These are examples of an ontogenetic change of function. There are many examples of change of function by suppression of the original or chief function, what was a minor use becoming the chief one. Examples of a phylogenetic change of function are the transformation of the jaws of biting insects into the needlelike elements, aiding in the formation of the beak of bugs (q.v.); the transformation of the hypopharynx of caddis flies into the piercing organ of fleas and flies; the modification of the maxillae of biting insects into the spiral tongue of the butterfly. The mouth parts of bees and butterflies lost their primitive functions and adopted entirely new shapes and uses after flowers appeared. Among fishes the clearest example is the change of the swimming bladder of the gar pike, where it also functions as a breathing organ, until in the lungfishes, which have probably descended from some ganoid, it becomes a lung.

CHANGE OF LIFE. See MENOPAUSE.

CHANGELING, a child left or taken in the place of another. It was at one time a common superstition that young children were liable to be stolen or changed by fairies before being baptized; and hence they were carefully watched till that ceremony was over. It was thought that the fairies were always anxious to change their own starveling elves for the more robust children of men. The children so left were called changelings, and were known by their greater backwardness in growth or learning; hence, stunted or idiotic children were regarded as changelings. The poets allude to this superstition occasionally, for example, William Shakespeare and Edmund Spenser.

CHANGO, chāng'gò, a tribe of South American Indians inhabiting the rainless region of northern Chile, near the Atacama Desert. Their territory was formerly much larger, and their language, now extinct, appears to have been a distinct stock.

CHANGSHA, chāng'shā', city, China, capital of Hunan Province, situated on the right bank of the Siang River 45 miles south of Lake Tungting Hu. A wall pierced by 12 gates formerly surrounded the city; the first such wall was said to have been built about 202 B.C. Changsha was a notable literary center at an earlier period; the city's university has existed for some 700 years. Foreign missionaries were first permitted to work at Changsha in 1901. An American college known as Yale-in-China was established in the vicinity. Manufactures include silk, linen, and brassware. The city became a treaty port in 1904. It was unsuccessfully besieged by Taiping rebels in 1852. There were revolutionary outbreaks in Changsha in 1910-1911, and again in 1930; in 1941, during World War II, the city was occupied temporarily by the Japanese, and they were again in possession from June 21, 1944, until the end of the conflict. Pop. (est. 1936) 311,600.

CHANGTEH, chāng'dū', city, China, in Hunan Province, on the left bank of the Yuan (Yuen) River near its mouth. It is in the midst of China's most fertile rice-growing area and has a considerable river-borne trade. The city was one of the treaty ports. During World War II Changteh suffered much damage in attacks by Japanese aircraft prior to its capture in 1944. Pop. (est.) 300,000.

CHANK, chāngk, the large, spiral shell of a gastropod mollusk (*Turbinella pyrum*) found in water from 12 to 15 feet deep along the shores of Ceylon and India. The shell is a sacred emblem of Vishnu, who is often represented as holding a "sinistral" one in his hand. They are used by the Hindu women as bangles and leg ornaments, or anklets. The chank appears as a symbol on the coins of some of the ancient Indian empires.

CHANLER, Amélie Rives. See RIVES, AMÉLIE, PRINCESS TROUBETZKOY.

CHANLER, chān-lēr, William Astor, American explorer: b. Newport, R. I., June 11, 1867; d. Mentone, France, March 4, 1934. He studied at Harvard, but left the university to make explorations in Africa. With Chevalier Ludwig von Höhnelt, he started from Zanzibar in September 1892 to explore the region east and west of Mount Kenya. They reached the coast on the return journey June 1893. He was elected to the New York legislature in 1897 and to Congress in 1898 as a Democrat. He served in the Spanish American War and was commended in General William R. Shafter's reports. He wrote *Through Jungle and Desert* and *Travels in East-ern Africa*.

CHANNEL ISLANDS, an archipelago in the English Channel, 10 to 30 miles off the west coast of Manche Department of France, belonging to Great Britain. The group, with an aggregate area of 75 square miles, comprises Jersey (45 square miles; pop., 1948, 57,133), Guernsey (25 square miles; pop., 1949, 44,592), and the following dependencies of Guernsey: Alderney, Brechou, Great Sark, Little Sark, Herm, Jethou, and Lihou. St. Helier, the principal town of Jersey, is on the south coast, 122 miles south-southwest of Southampton; the principal town of Guernsey is

St. Peter Port. The islands, which are picturesque and very fertile, export large quantities of fruit, vegetables, and flowers to the English market. The chief fertilizer is vraic, a type of seaweed, the regular gathering of which, controlled by legislation, is one of the characteristic insular scenes. Much kelp is used in the manufacture of iodine. The Channel Islands are celebrated for a special breed of cattle, originally called Alderney but now differentiated as Jerseys and Guernseys which differ in several minor characteristics. There are important fisheries of turbot, conger eels, oysters, lobsters, and monster crabs. The quarries of Jersey and Guernsey are extensively worked, and export fine granite for building purposes. Lieutenant governors head the administrations of the two largest islands. In both Jersey and Guernsey is a bailiff who presides over the Assembly of the States (the legislature) and is also president of the Royal Court (the judiciary). While French is the official tongue for ceremonial or official occasions, English is permissible in the legislatures, most members of which are elected. Among the farming population the vernacular is old Norman French, which differs in peculiarities of spelling and pronunciation in each island and even in parishes of the same island. Ecclesiastically, the Channel Islands belong to the Anglican diocese of Winchester. Scheduled ship and air services link the islands with both Britain and France.

Cave dwellings and numerous megalithic cromlechs, tumuli, and menhirs prove the habitation of a prehistoric race. The Romans occupied the islands during the 3d and 4th centuries; Caesarea (Jersey) and Sarnia (Guernsey) occur in the *Antonini Itinerarium*. Earthworks, fortifications, and castles dating from Roman and subsequent periods exist. Christianization dates from the 5th or 6th centuries; St. Helier, chief town of Jersey, was named for one of the early evangelists. In 933 the Channel Islands passed into the possession of the dukes of Normandy. A few old Norman chapels remain, and the oldest extant churches—Saint Brelade's, on Jersey, and Saint Sampson's, on Guernsey—date from 1111. The islands became part of the British realm at the time of the Norman Conquest in 1066, and remained so after 1204, when Normandy was conquered by the French. In 1360, by the Treaty of Bretigny, Philip II of France recognized British claims to the islands, but subsequently there were many attempts on the part of France to capture them. Between 1460 and 1465, during the Wars of the Roses, the French actually held part of Jersey. During the Civil War there were rival royalist and parliamentary administrations in Jersey and Guernsey, the islands suffering severely as a result. French forces made two attempts to capture Jersey in the American Revolution, but both proved unsuccessful. The islands have frequently been an asylum for political refugees. Prince Charles (later Charles II) and Edward Hyde, 1st Earl of Clarendon, went to Jersey in the Civil War, and many Frenchmen fled to the islands during the revolutionary period in France. Victor Hugo lived as an exile in Jersey (1852–1855) and Guernsey (1855–1870), and Gen. Georges Boulanger went to live in Jersey in 1889. With the surrender of France in 1940 the islands were demilitarized and partly evacuated, and they remained in German occupation until the end of World War II in Europe. Some of the islands, notably Alderney, were used for the imprisonment

of Russian soldiers and the internment of Jews. The German garrison of about 27,500 men was surrendered to British forces on May 12, 1945. Considerable criticism was subsequently voiced in Britain concerning the lengths to which some local officials had gone in cooperating with the Germans.

Consult Foord, E., *The Channel Islands* (London 1928); Guerin, B. C. de, *The Norman Isles* (Oxford 1949).

CHANNELBILL, chān'ēl-bīl, a gigantic Australasian cuckoo (*Scythrops novaehollandiae*), having the size, flight, and general appearance of a hawk, brown and gray above and whitish below, with bare scarlet skin surrounding the eyes. It takes its name from two deep grooves in the side of the bill. It is probably parasitic, feeds on both fruit and insects, is migratory, and utters a shrieking cry like the syllable "krok."

CHANNELS, of a ship, pieces of wood or iron projecting edgewise like a ledge from the ship's outside, abreast of and extending somewhat behind the masts. They serve to extend the shrouds.

CHANNING, Edward, American historian: b. Dorchester, Mass., June 15, 1856; d. Cambridge, Mass., Jan. 7, 1931. He was the son of William Ellery Channing, 1818–1901 (q.v.). In 1878 he graduated at Harvard, and in 1883 he became instructor in history there, then assistant and full professor, and later McLean professor of ancient and modern history. He wrote *The Narragansett Planters* (1886); and *Town and County Government of the English Colonies in North America* (Johns Hopkins Studies, 1883–1884); *Columbus and His Companions*, in Winsor's *Narrative and Critical History of the United States* (1888); *The United States, 1765–1865* (1896); in collaboration with A. B. Hart and F. J. Turner, *Guide to the Study of American History* (1912); and with T. W. Higginson, *English History for Americans*. His notable *History of the United States* was in six volumes: Vol. I, *The Planting of a Nation in the New World, 1000–1660* (1905); Vol. II, *A Century of Colonial History, 1660–1760* (1908); Vol. III, *The American Revolution, 1761–1789* (1912); Vol. IV, *Federalists and Republicans, 1789–1815* (1917); Vol. V, *The Period of Transition, 1815–1848* (1921); Vol. VI, *The War for Southern Independence* (1925), awarded the Pulitzer prize as the best volume of the year on this history of the United States.

CHANNING, chān'ing, Edward Tyrrel, American scholar: b. Newport, R. I., Dec. 12, 1790; d. Cambridge, Mass., Feb. 8, 1856. He was a brother of William Ellery Channing, 1780–1842 (q.v.). He studied law and was admitted to the bar, but gave his attention chiefly to literature. The *North American Review*, the earliest permanent publication in the United States, was issued in May 1815 as a bimonthly; the quarterly publication was not adopted until the commencement of the eighth volume. William Tudor edited it for two years, and in 1817 it passed under the control of a club. Jared Sparks (q.v.) was chief editor for one year, when the duty was undertaken by Channing, aided by his cousin, Richard Henry Dana (q.v.). In October 1819, Channing was succeeded in the editorship of the *Review* by Edward Everett, having been appointed Boylston professor of rhetoric and oratory in Harvard University. This post he held for 32 years, resigning it in 1851. During all this

time, the department of rhetoric and oratory, including the charge of all the English compositions of the students which had great influence over their reading and taste, was filled by him with more than satisfaction to the public of reading and thinking men. A volume of his letters was published in 1856 with a memoir by R. H. Dana.

CHANNING, William Ellery, American Unitarian clergyman: b. Newport, R. I., 7 April 1780; d. Bennington, Vt., 2 Oct. 1842. Entering Harvard College at 14 he took his degree in 1798 and though at first inclining to the study of medicine, presently decided upon the profession of the ministry. After his graduation he spent two years in Virginia as a tutor, but in pursuance of his ascetic views regarding renunciation and the necessity of subduing the animal nature, he endeavored to accustom himself to hardships during this period, even denying himself sufficiency of food and clothing. The result of this unwise course was to implant in him the tendency to disease that made him for the greater part of his career a semi-invalid. Returning from Virginia he took up the study of theology, making at the start a careful study of the evidences of Christianity, wishing, as he said, to know what Christ taught and not what men made him teach. In 1801 he was made regent of Harvard, the duties of this office being light and the salary sufficient for his support while continuing his studies. In 1802 he preached his first sermon at Medford, Mass., from the text "Silver and gold have I none; but such as I have, give I thee." In 1803 he was ordained pastor of the Federal Street Church in Boston and continued in that relation for the rest of his life. In the earlier years of his ministry the denominational spirit was not especially strong in him and with the ministers of the Trinitarian churches in Boston, he was on most friendly terms. His opinions were ripening during this period, however, and in 1819, at the ordination of Rev. Jared Sparks in Baltimore, he preached a sermon in which for the first time he gave free expression to the principles of Unitarian Christianity, upholding the exercise of reason in religious matters; declaring the Bible to be "a book written for men in the language of men and its meaning to be sought in the same manner as that of other books." He also objected to the doctrine of the Trinity, affirming his belief that Christ was distinct from and inferior to God, and sent to men as a great moral teacher, not as a mediator between erring man and offended deity. This discourse gave rise to much controversy and fixed definitely the Unitarian position as distinguished from that of the Trinitarians. It made him, moreover, the recognized leader of American Unitarianism, and much as he disliked controversy he never hesitated from uttering what he believed to be true because of hostile criticism. His greatest dread was of becoming creed-bound and thus losing perception of new truths, and he even spoke of himself as "little of a Unitarian," and standing aloof "from all but those who strive and pray for clear light, for a purer and more effectual manifestation of Christian truth." After 1824 Rev. Ezra Stiles Gannett was associated with him in the ministry of the Federal Street parish and from this epoch his time was largely

given to philanthropic and literary work, the asceticism of his youth having long since been supplanted by a more wholesome understanding of life and its requirements and duties. He visited Europe in 1822 and became acquainted with Coleridge and Wordsworth. He was one of the first to acknowledge the greatness of the latter, and save Shakespeare, he read no poet oftener. Channing was a fearless defender of freedom and upheld Garrison when that great abolitionist was the most generally detested person in Boston. In the pulpit his mission, as he saw it, was to free men's minds from servile conceptions of God, to disabuse religion of its benumbing terrors and to show forth to men the real significance of their moral natures. His writings on theological, social and philanthropic themes have received the widest circulation and been translated into French, Italian, German, Icelandic, Russian and Hungarian. The most notable of them include 'Evidences of Revealed Religion'; 'Essay on National Literature' (1823); 'Remarks on the Character and Writings of John Milton' (1826); 'Character and Writings of Fénelon' (1829); 'The Duty of the Free States' (1835); 'Negro Slavery' (1835); 'Self Culture' (1838). He had a life-long abhorrence of slavery, but in his 'Duty of the Free States' his feelings on the subject find fullest expression. His name, moreover, was associated with the most of the social reforms of his day and besides bearing a part in the great anti-slavery agitation, he warmly sympathized in the temperance movement, was an ardent lover of peace and deeply interested in schemes for educational advance. He stood for intellectual and spiritual ideas and foresaw dangers both to nations and individuals in the spread of materialism, in the contented adoption of inadequate aims, complacent satisfaction with perishable interests. In an age when comparatively few religious leaders dared to think outside of narrow prescribed limits, Channing stood forth as the intellectual champion of freedom. Much of his influence may have been due, no doubt, to the singular sweetness of his disposition and his entire nobility of character, but more of it was due to the fact that he spoke with utter fearlessness and thus inspired other men to free themselves from the fetters of dogma or of intellectual timidity. Although two generations have passed since his death, his name is still both familiar and beloved and his beneficent influence, far from lessening its hold upon men, has deepened and widened with the years. Channing's literary style, while not highly ornamental, was both clear and vigorous and his sentences were usually short and direct, though it is said that his personal preferences in the writings of others were for long and involved sentences. On 1 June 1903, a bronze statue of Channing by Herbert Adams was unveiled in the public garden in Boston, Mass., its site being opposite the Arlington Street Church, the successor of the Federal Street Church, of which he was so long pastor. The statue and its monumental setting were the gift of John Foster to the city. Consult 'Lives' by W. H. Channing and C. T. Brooks (3 vols., London 1848, and reprinted Boston 1880); 'Correspondence of Channing and Lucy Aiken'; Peabody, 'Reminiscences'; Chadwick, 'W. E. Channing' (Boston 1903).

and Eliot, *Four American Leaders* (Boston 1906).

CHANNING, William Ellery, American poet, nephew of William Ellery Channing, the elder: b. Boston, Mass., June 10, 1818; d. Concord, Mass., Dec. 23, 1901. After some years spent in newspaper work he retired to Concord, where he lived the life of a recluse. His writings include *Poems* (1843-47); *The Woodman* (1849); *Near Home* (1858); *The Wanderer* (1871); *Thoreau, the Poet-Naturalist* (1873); *Eliot* (1885); and *John Brown and the Heroes of Harper's Ferry* (1886).

CHANSONS DE GESTE, shān-sōn'dē zhěst', epic poems of the Middle Ages. Gaston Paris (1839-1903), one of the great authorities on French medieval poetry, has defined the *chanson de geste* as a song of which the subject is a series of historical facts. One might also describe it as an historical romance in poetic form. The French word *geste* (deriving from the Latin *gesta*) means fact, deed, also feat; and indeed these songs, the prime poetic achievement of France between the 11th and 13th centuries, deal mainly with historic and fabulous feats of arms. The most famous of them, the *Chanson de Roland* (q.v.), a poem in 10-syllable lines, is the earliest, its composition dating from the latter half of the 11th century. The anonymous author is believed to have lived at or near Mont Saint-Michel in Normandy at the time of the conquest of England; but that he was one of Duke William's vassals in that exploit is a mere conjecture. There is evidence that the *Roland* was written after 1066 but before the First Crusade (1096-1099). Roland, one of Charlemagne's paladins, fell in the valley of Roncesvaux on August 15, 778, heroically defending the rear guard of the emperor's army retreating out of Spain against Basque onslaughts. This disastrous battle in the Pyrenees occurred three centuries before the epic narrative was penned on parchment by an 11th century poet, and by that time the hero had already become a legendary figure. The glorification of a warrior of an epoch long past is characteristic of the *chansons de geste*.

Sung by the *trouvères* these poems are essentially masculine and northern in spirit, differing in form, theme, and spirit from the lyric poetry which the *troubadours* were producing in the same period in the more imaginative, complex and advanced civilization of Provence. They were composed mainly for male auditors in a region of France and at an epoch when the military tradition was dominant, the qualities of the knight at arms held in highest esteem and when prowess in battle was accounted the supreme male virtue. The troubadour poetry, on the other hand, was for feminine listeners and readers, to charm them with tales of tender love and eternal devotion. The southern poets were far more interested in the joy of life and love than in the rude shock of battle and a hero's death. Often they dedicated their verses to the queens of the little kingdoms who were their generous patrons.

A salient characteristic of the northern epics is their deep religious and national feeling. With the exception of the *Roland*, however, these poems, mostly by unknown authors, reveal only a rudimentary knowledge of literary con-

struction. As a rule, the narrative is rambling and diffuse; the versification is rough; the characters lack shading, being all white or all black; and moral problems are all but nonexistent. Yet despite these many defects they express an undeniable primitive force and sincerity as well as profound religious sentiment. Above all they express an intense love of the native soil, a noble patriotism unexcelled in the poetry of more civilized epochs. They were, undoubtedly, largely influential in fostering the spirit of Christian chivalry that flowered during the Crusades.

Epic Poetry and the Chansons de Geste.

—Leon Gautier (1832-1897), the foremost authority on the *chansons de geste*, points out that of the three kinds of poetry—lyric, epic and dramatic—historically the epic is of more recent growth than the lyric, while dramatic poetry developed last of all. He makes a distinction between kinds of epic poetry, dividing the category into "natural" and "artificial" epics. The prime characteristic of the natural epic is its legendary quality. Like the Homeric poetry it is the cradle song of a people in the infancy of their civilization. All natural epics are songs of the people. Artificial epics, on the other hand, belong to a later stage of civilization, and have been written for cultivated tastes. As examples of the natural epic Gautier cites the *Iliad* and the *Chanson de Roland*; while to the class of the artificial he assigns Virgil's *Aeneid*, Tasso's *Jerusalem Delivered* and Voltaire's *Henriade*, the only notable modern French epic.

The natural epic, again according to Gautier, requires four conditioning circumstances: (1) A primitive period when science and criticism are virtually nonexistent, when history and legend are easily confounded, and credulity is general. (2) A national and religious environment that has developed in a country which has achieved a measure of national unity, as was the case in France when the *chanson de geste* was, in effect, the great war cry of Christianity against Islamic invasion; and when religious and patriotic concepts are difficult to distinguish. (3) Extraordinary and grievous events. Tragedy is the prime element of the epic. A defeat and a heroic death are the subjects of most of these virile songs, replete with blood and tears and almost devoid of the emotion of joy. With grief there is room only for saintliness: the central figures of the three major cycles are St. Charlemagne, St. William and St. Renaud. (4) Heroes who are the personification of an entire nation in an historical epoch. Just as Achilles personified the Greek race at a certain stage of its history, so Roland represents the chivalrous France of the 10th and 11th centuries.

To sum up these essentials of the natural epic: a primitive epoch for its creation; a national and religious environment; extraordinary and tragic events; and, finally, a hero who is the personification of an entire country and an historical epoch.

The Cycles.—A cycle in the meaning of the term as applied to epic poetry may be defined as a group of poets and poems dealing with an event, a hero, or a notable family. The central figures of the three major French cycles are Charlemagne, Duke William Shortnose and Renaud de Montauban. The Charlemagne cycle, most famous of all, is called *La Geste du Roi*;

that of Duke William, *La Geste de Guillaume*, or, alternately, *La Geste de Garin de Montglane*; that of Renaud, *La Geste de Doon de Maïence*. This division of the earliest epics into three main groups owes nothing to the researches of modern paleographers; it was recognized by the trouvères themselves and explicitly stated in one of the chansons, *Girars de Viane*.

Gautier has divided the Charlemagne cycle into six subdivisions, the first of which deals with Charlemagne's mother, Bertha, and the personal life of the emperor himself until the appearance of Roland. To this group belong *Bertha Greatfoot* (*Berte aus grans piés*) and *Aspremont*, describing a fictitious campaign against a Saracen king in Calabria. The second group, known as the feudal epic, describes the emperor's struggles with rebellious vassals: it includes *Ogier the Dane*. In the third group are the poems describing Charlemagne and his peers on a quite legendary trip to the Holy Land. The best known of this group, the *Pilgrimage to Jerusalem*, affords the first example of Alexandrine verse (the 12-syllable line) used by a French poet. A fourth group deals with events before the Spanish war: it includes *Aiquin*, *Fierabras* and *Otinél*. The fifth concerns the war in Spain and includes the *Chanson de Roland*. The sixth and last treats with events after Roland's death to the death of Charlemagne in 814.

The *Geste de Guillaume* chansons of the 12th century include *Le Charroi de Nîmes*, *La Prise d'Orange* and *Le Moniage Guillaume*. They celebrate the duke's battles with the Saracens or with rebellious vassals of his suzerain, Louis the Debonnaire, Charlemagne's son. The *Moniage* abounds in heroicomic episodes, describing the duke's conversion to a holy life, his last exploits, retirement to a monastery, and issuing from it to deliver Paris from besieging Saracens (a fabulous event). Later the poets wrote of the hero's boyhood (*Enfances Guillaume*), his ancestors and his nephews. The 13th century poets were prolific narrators of youthful exploits of popular heroes. Thus they produced "enfances" of Charlemagne and Ogier the Dane, of Roland and Vivien (nephew of Duke William and the prototype of the young Christian hero who fights and dies for his faith). Even heroes of a more recent epoch, like the crusader Godfrey of Bouillon, king of Jerusalem, were thus honored. William, educated in Charlemagne's palace school at Aix-la-Chapelle, may have been a relative of the emperor. Historically we know little about him. In 792 his army was defeated by a Saracen horde of 100,000, but fought so valiantly that the invaders were forced to retire out of France. In 801 he captured Barcelona from the Saracens, and five years later retired to Gellone near Lodève (Hérault) where he founded a monastery of which he was abbot until his death in 812. After his canonization the monastery was named Saint-Guilhem-du-Désert.

La Geste de Doon de Maïence, third cycle of the Charlemagne romances, deals with revolts against Charlemagne of members of the family of the archtraitor Ganelon who betrayed Roland to his death at Roncesvaux; wherefore it is sometimes called "*la faulse geste*." It includes some of the most famous chansons, such as *Parise la Duchesse*. The *Four Sons of Aymon* and *Huon de Bordeaux*. Doon of Mayence (i.e.,

Mainz, near the confluence of the Rhine and the Main) is represented as the father and grandfather of revolting barons. He had twelve sons, one of whom was the father of Ogier the Dane, another of Ganelon, and a third of Huon. Renaud of Montauban, one of the four sons of Aymon, is the principal figure in this cycle. After enduring fearful sufferings and exile he at last makes his peace with Charlemagne. Although the authors of these chansons strove to achieve a kind of unity by providing a common ancestor for their heroes, they were not at all troubled over implausibilities and manifest anachronisms. There was a misty tradition of a traitorous family in Mayence, but the exploits of the barons of the chansons, if they have any basis of fact must have occurred either before or after Charlemagne's time. These vassals' contemptuous and insolent attitude toward the Emperor of the West who ruled half of Europe was certainly not that of the very few who dared challenge that supremely powerful monarch. However, their scorn of the suzerain may well have reflected attitudes toward the earlier Frankish kings and the weaker Carolingian sovereigns who succeeded Charlemagne.

Minor Cycles.—There are seven or eight secondary cycles. In the ancient eastern Gallic kingdom of Austrasia, cradle of the Carolingian dynasty, the sanguinary and savage chansons of the Lorrainers developed. These epics constituted a cycle of hatred and private wars of vengeance, making it preeminently the feudal cycle. The cycle of Raoul of Cambrai originated in Vermandois. There were also those of Aubri the Burgundian and Elie of St. Gilles. Later a malady which Gautier ironically calls "cyclic monomania" afflicted the poets and they attempted to establish family relationships between the heroes of these minor cycles and those of the three major.

The last cycle was that of the Crusaders. Godfrey of Bouillon (1061-1100) and Peter the Hermit were its leading figures. Actually, the spirit of the Crusades animated all the cycles, and hardly had the first French king of Jerusalem died than the age of the great epics ended. Commencing with Charlemagne and ending three centuries later with Godfrey, the great epic cycles closed with a fitting celebration of the noblest representative of chivalry of his day.

Manuscripts of hundreds of chansons de geste are preserved in French archives. Many of them have never been published, and most of these would doubtless be interesting only to students. But the influence of the epics of the major cycles permeates all of Western literature. Oberon, king of the fairies, one of the characters in *Huon de Bordeaux*, was borrowed by Spenser and Shakespeare. Dante, Tasso and Ariosto owed a debt to these martial poems of medieval France. Indeed, every poet of later ages who attempted the epic found in them a source of inspiration. As Shakespeare, better than any other author, expresses the English spirit, so the chansons de geste portray the indomitable spirit of France.

DRAKE DE KAY,

Editorial staff, "Encyclopedia Americana."

CHANT, a short musical composition adapted to the singing of the psalms and canticles. Chants are single when adapted to a single verse, and double when adapted to two verses, the former consisting of two strains of three and four bars respectively, and the latter being twice that length. More recently quadruple chants extending over four verses have been introduced. The complete chant consists of four parts, namely: (1) The intonation or initial phrase leading up to the reciting note; (2) the reciting note, which is the dominant of the mode employed; (3) the mediation, or main body of the chant; and (4) the termination or concluding phrase. In modern Anglican chants, however, there is no intonation. The origin of the plain song of the Church is unknown, but the first attempt to reduce the traditional music to some definite system was made by Saint Ambrose, bishop of Milan (d. 397). More important, however, by far is the Antiphonarium of Gregory the Great, which appeared in the latter half of the 6th century and soon established itself as the chief and in fact only authority on Church music. The Gregorian tones were introduced into England by Saint Augustine, and in the course of their history in that country they underwent many modifications in the various local "uses." During the civil war and the Commonwealth they went out of use, but were revived at the Restoration. Not long afterward, however, the Gregorian chants began to give place to the modern double chants, and it is only in quite recent years that attempts have been made to revive them. A new impetus has been given to the use and popularization of plain chant in recent times by the first encyclical letter of Pius X, his "*motu proprio*" and the introduction of Gregorian music in all the Catholic churches throughout the world. See also GREGORIAN CHANT.

CHANT DU DEPART, shān dü dā-pār (Fr. "Song of Departure"), a popular French military song of the period of the Revolution, written by the poet Marie Joseph Chenier, to the music of Méhul. The occasion for its composition was the celebration of the fifth anniversary of the taking of the Bastille.

CHANT ROYAL, a verse form invented by medieval French poets. Some students consider it a development of the ballade (q.v.), but it is a matter of conjecture as to which form preceded the other. It can be roughly defined as a ballade of five stanzas, each consisting of eleven lines, with a five-line envoi. The first stanza contains five rhymes which are used in the same order throughout, but only two rhymes are used in the envoi; the sixty lines of the poem consequently have only these five rhymes. As in the ballade the last line of the first stanza becomes a refrain, repeated at the end of each following stanza and the envoi. The rhyme scheme for the stanzas is *a b a b c c d d e d e*, and for the envoi, *d d e d e*.

Edmund W. Gosse (q.v.) who wrote one of the few English examples (indeed, he was the

first poet to compose in this form in English) states that "the chant royal is the final *tour-de-force*, the *ne plus ultra* of legitimate difficulty in the construction of a poem. Henri de Croi [in *Ari et science de rhétorique* (1493)] derives the title from the fact that persons excelling in the composition of *chants royaux* were worthy to be crowned with garlands like conquerors or kings." Gosse adds that the chant royal "was always dedicated to more stately and heroic themes than the ballade. The chant royal was reserved for the celebration of divine mysteries, or for the exploits of some heroic race." The most admirable are those of Clément Marot (q.v.), the protégé of Francis I who shared his sovereign's disaster at Pavia (1525) when all was lost *hors l'honneur*. The *Chant Royal, Chrestien* was Marot's most noted achievement in this form. Its refrain, "*Santé au corps, et Paradis à l'âme*, expresses the Christian's longing for physical health and happiness on earth and the soul's salvation hereafter—a contradictory aspiration, warns the poet, since Christ has promised his followers in their earthly existence only trouble, pain and sorrow.

Eustache Deschamps (1340-1410) describes a variant popular in the Middle Ages, in praise of the Virgin Mary. These Marist chants royaux differ only in lacking the envoi.

Jean de la Fontaine (q.v.) was the last of the classicists who attempted a supremely difficult form. Only toward the end of the 19th century with the revival of interest in antique verse forms—ballade, rondel, rondeau, villanelle, triolet—did French and English poets seek to revive it. Gosse's *The Praise of Dionysus* (1877) and *Death of Death* by Henry Austin Dobson (q.v.) follow the classic form and spirit.

Henry Cuyler Bunner (1855-1896), American poet, wrote what is probably the only comic chant royal by a poet of high technical ability. Two of the stanzas and the envoi will suffice to exemplify the structure and rhyme arrangement adapted to a mock heroic theme

BEHOLD THE DEEDS!

(Being the Complaint of Adolphe Culpepper Ferguson, Salesman of Fancy Notions, held in durance of his Landlady for a failure to connect on Saturday night.)

I.

I would that all men my hard case might know;
How grievously I suffer for no sin:
I, Adolphe Culpepper Ferguson, for lo!
I of my landlady am locked in,
For being short on this sad Saturday,
Not having shekels of silver wherewith to pay:
She has turned and is departed with my key:
Wherefore, not even as other boarders free,
I sing (as prisoners to their dongeon-stones
When for ten days they expiate a spree):
Behold the deeds that are done of Mrs. Jones!

V.

Thou, for whose fear the figurative crow
I eat, accused be thou and all thy kin!
Thee will I show up—yea, up will I show
Thy too thick buckwheats, and thy tea too thin.
Ay! here I dare thee, ready for the fray;
Thou dost not "keep a first-class house," I say!
It does not with the advertisements agree.
Thou lodgest a Briton with a puggaree,
And thou hast harbored Jacobes and Cohns,
Also a Mulligan. Thus denounce I thee!
Behold the deeds that are done of Mrs. Jones!

Envoy.

Boarders! the worst I have not told to ye:
She hath stolen my trowers, that I may not flee
Privily by the window. Hence these groans.
There is no fleeing in a robe de nuit.
Behold the deeds that are done of Mrs. Jones!

Consult Murray, M. W., and Casati, E., *Four Centuries of French Poetry* (London 1935).

CHANTABON or **CHANTABUN** or **CHANTIBUN**. See **CHANTHABURI**.

CHANTADA, chān-tā'thā, town, Spain, in Lugo Province, is located 20 miles northeast of Orense, on the Chantada River, a branch of the Miño, in an agricultural area producing livestock, grain, flax, and potatoes. Its industries are tanning, ham processing, and linen manufacture. It also has mineral springs. An old Roman bridge crosses the Miño about three miles east of the town. Pop. (1940) 1,552.

CHANTAL, shān-tāl', **BARONNE DE** (née **JEANNE FRANÇOISE FRÉMIOT**; later known as **SAINTÉ CHANTAL**; also **ST. JANE FRANCES DE CHANTAL**), French religious: b. Dijon, France, Jan. 28, 1572; d. Moulins, Dec. 13, 1641. After the death of her husband, Celse de Rabutin, baron de Chantal, in 1601, she devoted her life to charity; and in 1610, assisted by St. Francis de Sales, she founded the Congregation of the Visitation of Our Lady, at Annecy. (See **ORDERS, RELIGIOUS**—*Visitation Nuns*.) She was superior of its house in Paris (1618-1622). Beatified in 1751 and canonized in 1767, her feast day is August 21.

CHANTAVOINE, shān-tā-vwān', **Henri**, French poet and historian: b. Montpellier, France, Aug. 6, 1850; d. Caluire (Rhône), Aug. 15, 1918. He was educated at the École Normale, Paris, and became professor of rhetoric at the Lycée Henri IV. He contributed to the *Nouvelle Revue* from its founding in 1879, and in 1884 joined the *Journal des Débats*. His published volumes of poems include *Poèmes sincères* (1877); *Satires contemporaines* (1880); *Ad memoriam* (1884); *Au fil des jours* (1889). His historical works include *Histoire de Pinchu* (1906); *Les Principes de 1789* (1908).

His son, **JEAN CHANTAVOINE** (b. Paris, May 17, 1877; d. Mussy-sur-Seine, July 16, 1952) was music critic of *Revue Hebdomadaire* (1903-1920); also of *Excelsior*, of *Ménestrel*, and other publications (1911-1921); general secretary of the Paris Conservatoire from 1923. He recovered the score of Franz Liszt's lost opera *Don Sancho* which he describes in his *Musiciens et Poètes* (1912). He is also the author of *Beethoven* (1906); *Liszt* (1910); *De Couperin à Debussy* (1921); *Les symphonies de Beethoven* (1932).

CHANTECLER, shān-t'klār'. The most original play of the French poet and playwright Edmond Rostand, although by no means his best, is *Chantecler*, produced in Paris in 1910. The public, which had first been captivated by the dashing *Cyrano de Bergerac*, and then charmed by the more ambitious *L'Aiglon*, had for a decade yearned for another piece from the poet's pen. When it came, after judicious heralding, it proved, to many, something of a disappointment. A *tour de force*, brilliant, witty, and novel, it was nevertheless seen to stand apart from the main development of the modern drama. Rostand, as a romanticist, had sought to clothe with unconventional garb figures to be used in a satire. From his observation of barnyard animals he caught the notion of presenting contemporary society in hide and feathers. Accordingly, he offered a

dramatic fable, its central theme the faith of Chantecler, the cock, in his mission as the bringer of the dawn.

Chantecler believes that his joyous song directly evokes the sunrise. Great is his distress to find, when the envious hen pheasant has screened his eyes with her wing and made him forget his task, that the dawn has brightened without him and that he and his work are of little moment in the scheme of creation. Yet he will leave the forest, whither the hen pheasant has beguiled him, and return to his barnyard to proclaim, though he cannot produce, the day. His companion, freshly enthralled by this evidence of his courage in defeat, flies up to protect him by diverting to herself the attention of a hunter, but, caught in a snare, she dies. Incidentally, the play laughs at the social climbers who attend the guinea fowl's five o'clock tea, at the cynical blackbird, the fancy cocks who are fops and faddists, and the spiteful birds of night. More sympathetic are the hero, Patou the dog, a good old idealist, and the hen pheasant, who represents woman the enchantress, piqued by man's devotion to his work, yet ready to lay down her life for him.

The style of this fantasy is a marvelous mixture of poetry and slang, witty quips and smart local allusions jostling passages of lyrical beauty. No translator could hope to render its rich and poetic quality, although the English versions of Gertrude Hall (1910) and J. S. Newberry (1911) are worthy attempts toward this end. M. F. Liberma has written a critical analysis of the play entitled *The Story of Chantecler* (1910).

FRANK W. CHANDLER.

CHANTERELLE, shān-tē-rēl', a small edible mushroom (*Cantharellus cibarius*), yellow to orange in color, rather unsymmetrical in form growing in woods. See also **MUSHROOM**.

CHANTEY, shān'ti; chán'ti (also **CHANTE SHANTEY**, or **SHANTY**), a song of English and American sailors, generally sung to accompany group tasks associated with sailing vessels. Some chanties set the rhythm for reefing the sail, some for pumping, others for hoisting anchor. Among the most famous are *Mobile Bay*; *The Banks of the Sacramento*; *The Rio Grande*.

Consult Concord, J. C., *Songs of American Sailors* rev. ed. (New York 1938).

CHANTHABURI, chān-t'hā-bōō-rē, **CHANTABURI** (also **CHANTABUN**, chān-t'hā-bōōn), town, Thailand, capital of Chanthaburi Province, is located about 135 miles southeast of Bangkok, on the Chanthaburi River, near the Gulf of Siam. It has a deepwater port called Laem Sing. The surrounding area raises rice, pepper, coffee, and kapok; there are fisheries and a handicraft industry. Semiprecious stones are mined in the region. The population is largely Annamese and Cambodian. Originally a part of the Khmer Empire, the town passed to Thailand in 1576. Occupied by the French in 1893-1894, it was called Chantabon. Pop. (1947) province 110,808; town, 6,711.

CHANTILLY, shān-tē-yē', town, France, Oise Department, about 25 miles northeast of Paris, is a racing center and favorite Paris resort. Its industries are sawmilling and the manufacture of porcelain. It also ships mushrooms. The manufacture of Chantilly lace, for which it is formerly known, has declined. Chantilly has

tiful châteaux, the smaller of which is re-
lated as one of the finest specimens of French
renaissance architecture. The larger château
built for Louis II, prince de Condé, (1621-
55), called the great Condé who entertained
the most brilliant men of the time, in-
cluding La Fontaine, Racine, Molière, Boileau,
La Bruyère, and La Fontaine. This château was
destroyed during the French Revolution, but an-
other was built on its site by Henri d'Orléans,
duc d'Aumale, heir of the last Condé, and was
presented by him with its grounds, gardens, for-
tification, library, and art collection to the Institut de
France in 1886. The town was the general head-
quarters of the French Army in World War I.
N. (1946) 6,040.

CHANTILLY, shàn'til-ī, or **OX HILL**,
site of. On Aug. 31, 1862, the day after the
second Battle of Bull Run, Gen. Robert E. Lee
marched his army by way of Sudley Ford around
the John Pope's right at Centreville, Va., to
the Fairfax Court House and interpose between
him and Washington, D.C. Gen. Stonewall
Jackson was six miles west of Chantilly; Gen.
James Longstreet some distance in the rear.
Next morning, September 1, Jackson moved cau-
tiously toward Fairfax Court House and formed
on Ox Hill ridge, three miles east of Chan-
tilly, his artillery massed on the left of the road,
infantry on the right, extending in the direc-
tion of the Centreville road. He had not com-
pleted his formation when he became aware of
an approaching force from the Centreville road,
whereupon he strengthened his right and threw
off skirmishers.

About 1 P.M., Pope, who had heard of Jack-
son's advance toward his rear, sent Gen. Isaac I.
Stevens with about 3,000 men to gain the road
at Chantilly and to hold Jackson in check
until the Union Army could be brought into posi-
tion at Fairfax Court House. Stevens struck
Jackson's advancing skirmish line and drove it
back into a body of woods. Jackson then ad-
vanced a regiment from the woods, which also
was repulsed. Stevens next formed a column of
infantry (six regiments in three lines, two each
a line), placed himself in the center of this
column of 2,000 men, on open ground, and or-
dered it forward as the woods in front were
cleared.

The advancing column, ascending a gentle
slope, came to within 75 yards of the woods, when
a worm fence bordering them came a ter-
rible volley hitting the column with great effect,
falling by the score. At first the column
halted, but, quickly recovering, returned the
fire, five color bearers of the 79th New York
Infantry's old regiment, went down in succession.
The assault was checked. Stevens ran forward,
urged the colors, and called upon his men to
follow him. All rushed forward and gained the
position on which Stevens fell dead with a bullet
through his brain and the colors upon his head
and shoulders. The column advanced into the
woods.

At the moment that they reached the
woods a sudden and terrific thunderstorm and
burst over the field, blowing rain into the
faces of the men, impeding their movements, and
depleting their ammunition. Jackson brought up
his reserves, and after a contest of more than an
hour the six Union regiments were driven out
of the woods and fell back to the point where they
were formed.

Meanwhile three regiments of Gen. Jesse Lee
Reno's command had been committed on Stevens'
right, one only of which, the 21st Massachusetts,
became seriously engaged and was repulsed with
great loss. Gen. Philip Kearny now came up
with a battery, which he put in position, and went
to the right for a regiment to fill an interval.
He met the 21st Massachusetts as it came from
the woods and was leading it to the left, when
his attention was called to the fact that the
Confederates were advancing from the woods and
through a cornfield. He spurred his horse into
the cornfield to reconnoiter, ran upon a skirmish
line, saw his mistake, and turned to ride back,
when he was shot and killed. A sharp encounter,
ensuing between the 21st Massachusetts and the
Confederates, was ended by darkness: the regi-
ment withdrew, the Confederates retired to the
woods, and the battle was ended, neither side hav-
ing permanently gained a foot of ground. Pope
fell back to Washington, and Lee marched to
cross the Potomac into Maryland. The Union
loss was about 800 men; that of the Confederates
about 700.

E. A. CARMAN.

CHANTREY, chàn'trī, **SIR FRANCIS LEGATT**,
English sculptor: b. Jordanthorpe, Derbyshire,
England, April 7, 1781; d. London, Nov. 25, 1841.
He was the son of a carpenter and small farmer,
and at first worked for a grocer in the nearby
town of Sheffield. While there he noticed some
work in the window of a carver and gilder named
Ramsay and in 1797 became apprenticed to him
for seven years. J. Raphael Smith, a mezzotint
engraver, perceiving Chantrey's talent for draw-
ing and modeling, encouraged him. He received
his first instruction in oil painting from Samuel
James. By 1802 he was in London, studying at
the Royal Academy. His first commission was in
1805 from the people of Sheffield for a memorial
bust of the Reverend J. Wilkinson, to be placed
in the parish church. He exhibited regularly at
the Royal Academy and in 1808 was the suc-
cessful candidate for a statue of George III for
the Guildhall in London. Subsequently he exe-
cuted busts of a number of distinguished sitters,
including George IV, Sir Walter Scott, the duke
of Wellington, and the poet William Wordsworth.
In 1815 Chantrey was chosen an associate and
in 1818 a member of the Royal Academy. In
1819 he visited Italy to study in the galleries.
While there, he was elected member of the acad-
emies of Rome and Florence. He was knighted in
1835.

His most celebrated work is the *Sleeping
Children*, a monument erected to two children
of the Reverend W. Robinson, in Lichfield Cath-
edral. He left a fortune of about £150,000, which,
after the death of his widow, became the Chantrey
bequest to the Royal Academy for the annual
purchase of works of sculpture and painting exe-
cuted in Great Britain by living or recently de-
ceased artists.

CHANTRY, chàn'trī (Old Fr. *chanterie*), an
ecclesiastical endowment to provide for the cele-
bration of masses for the prosperity of the living
or the repose of the dead. Before the Reforma-
tion chantries were numerous, almost every family
of importance having founded one or more. Some-
times small chapels were appended to the main ed-
ifice of a church, and occasionally, as at Wakefield
and Bradford on Avon, in England, such chapels

were erected on bridges. The residences of priests engaged in the services were known as chantry houses, chantries, or colleges. The chantry schools were widely spread over England prior to the Reformation. Chantries were finally dissolved in England by Edward VI, and nearly all endowments were devoted to the purposes of the crown.

CHANUTE, shā-nōōt', city, Kansas, in Neosho County, at an altitude of 940 feet, on the Neosho River, 69 miles southeast of Emporia, and served by the Atchison, Topeka and Santa Fe and the Missouri, Kansas and Texas railroads and a municipal airport named after Martin Johnson, the explorer. Surrounding the city is an area of diversified farming, with extensive deposits of gas, oil, limestone, and clay. Chanute has railroad shops, a wax plant, oil refineries, and factories that produce oil tanks, brooms, men's work clothing, gas mantles, and cement. The city has several parks, a public library, a good public school system including a junior college, and an imposing municipal memorial building.

Settled in 1868, Chanute was incorporated in 1872. It was named in honor of Octave Chanute (1832-1910), railroad civil engineer and one of the pioneers of American aviation. In 1912 the city adopted commission form of government. Its water supply system, and the light, natural gas, and power systems, are municipally owned. In 1930 city tax levies were eliminated, cost of administration being covered by profits of the municipal utilities. Pop. (1940) 10,142; (1950) 10,109.

CHANZY, shān-zē', Antoine Eugène Alfred, French general and politician: b. Nouart, Ardennes, March 18, 1823; d. Châlons-sur-Marne, Jan. 4, 1883. After a course at the military school of Saint-Cyr, he became sub-lieutenant of infantry in 1843, and was sent to Algeria and eventually became major. He subsequently served in Italy and Syria, but on becoming colonel he returned to Africa in 1868. On the outbreak of the war with Germany in 1870 he was created a general of division, and after gaining the battles of Coulmiers and Patay, was put in command of the second army of the Loire. Here he fought heroically against the much stronger and more disciplined Germans, but finally had to retreat. He was elected to the National Assembly for the department of Ardennes, and during the Commune he narrowly escaped with his life. When peace was declared he was elected to the National Assembly and became in 1872 commander of the Seventh Army Corps. In 1873 he went to Algeria as governor, in 1875 was elected life senator and in 1879 he stood for the presidency. In that year also he was sent to Russia as ambassador, a post which he held until 1881, when he became commander of the Sixth Army Corps. He published *La deuxième armée de la Loire* (1871).

CHAOAN, chou'an', or **CHAOCHOW**, city, China, in the province of Kwangtung, on the river Han, 195 miles northeast of Hongkong. It is the center of an important maritime division of the province. The channel leading to it is very shallow, so that ships of large burden can sail up only at high water. This city was included in the Treaty of Tientsin (1858) as a port open

to foreign trade, but the foreign trade is transacted at Swatow. Pop. (1948 est.) 59,486; Chaoan county 620,785.

CHAOS, kā'ōs, according to the signification of the word, the void which embraces all things. Hesiod mentions, as the original principles of all things, Chaos, Earth, and Eros (Love); other ancient poets made Chaos alone the primeval source from which everything is derived; others added to it Night, Erebus, and Tartarus; and still others represented Chaos as the parent of the Earth and Heaven, after the production of which Eros completed the creation. Modern writers commonly understand by chaos the uniform primeval matter from which the universe was made. The word chaos is also used to denote utter confusion or disorder.

CHAPPAIS, shā-pē', Sir Thomas, Canadian journalist and statesman: b. Saint Denis, Quebec, March 23, 1858; d. there, July 15, 1946. He was graduated at Laval University in 1879 and was called to the bar in the same year. From 1879 to 1884 he was private secretary to the lieutenant governor of Quebec and from 1884 to 1901 edited *Le Courier du Canada* (Quebec). He became a member of the legislative council in 1892 and was made speaker in 1895. In 1893 he was a member of Sir Louis O. Taillon's cabinet and in 1897 was minister of colonization and mines. In the latter year he retired from public life and was appointed (1907) professor of history at Laval University. He was made chevalier of the Legion of Honor in 1902. His published works include *Les congregations enseignantes et le brevet de capacité* (1893); *Le serment du roi* (1901); *Jean Talon, intendant de la Nouvelle France* (1904); *Le marquis de Montcalm* (1911); *Cours d'histoire du Canada*, 8 vols. (1919-1934); *Discours et conférences* (1897-1935).

CHAPALA, chā-pā'lā, lake, Mexico, on the high plateau of Jalisco, surrounded by steep bare mountains. It has an estimated area of 417 square miles and contains many islands. The Rio Lerma is its chief tributary stream, entering from the east; its outlet is the Río Grande de Santiago.

CHAPARRAL-COCK. See ROAD-RUNNER.

CHAPBOOKS, a species of cheap literature, in the form of small pamphlets, which preceded the popular periodicals of the present day and were so called because prepared expressly for sale by the chapmen, or pedlars, who hawked them from district to district. They were largely productions of the provincial presses. The writers are mostly unknown, but one of the authors of Scottish chapbooks was Dougal Graham (1724-1779), bellman of Glasgow. Their matter was of the most varied character, including theological tracts, lives of heroes, martyrs, interpretation of dreams, fortune telling, weather forecasts, stories of ghosts, giants, and witches, and songs and ballads. After 1800 the chapbooks declined in popularity, and were succeeded by the penny magazine and other cheap publications. Collections of chapbooks can be found in many libraries. The New York City Public Library has an especially fine one, as does the Harvard University Library.

Consult Halliwell-Phillips, J. O., *Notices of Fugitive Tracts and Chap-Books*, published by the Percy Society (London 1849); Nisard, M. L. C., *Histoire des livres populaires* (Paris 1854); Fraser, John, *Humorous Chap-Books of Scotland* (New York 1873); Ashton, John, *Chap-Books of the Eighteenth Century* (London 1882); Faxon, Frederick W., "Ephemeral Bibles," in *Bulletin of Bibliographical Pamphlets* (Boston 1903); Harvey, William, *Scottish Chap-Book Literature* (Parsley, England 1903); "Catalogue of England and American Chap-Books and Broad-side Ballads in Harvard University," in *Bibliographical Contributions*, no. 56 (Cambridge, Mass. 1905); Mackensen, Lutz, *Die deutschen Volksbücher* (Leipzig 1927); Weiss, Harry B., *A Book about Chapbooks* (Trenton, N. J. 1942).

CHAPEAUX, shâ-pô' (Fr. *chapeaux*, hats), a name applied to the partisans of France in Sweden in the 18th century, while those favoring the cause of Russia were called Bonnets (caps). Having instigated war against Russia in 1741, and again in 1756, the Chapeaux declined in popularity for the calamities inflicted upon Sweden. Succeeding in 1769 in regaining their former position, the party was soon extinguished altogether by the advent of Gustavus III in 1772 and his reforms. The same names were also formerly applied in the Académie Française, the Chapeaux constituting the party supported by the philosophers and the public, and the Bonnets that party upheld by the clergy and the court.

CHAPEL, chăp'êl (Fr. *chapelle*, Lat. *capella*), a name for religious edifices of various kinds, especially for such as hold a subordinate position. In England and Scotland there are several kinds of chapels—parochial chapels, subordinate to, but distinct from, the mother church; chapels of ease, built for the accommodation of the inhabitants, in large parishes; university chapels, and private chapels, whose names explain their uses. The term is also applied to small buildings attached to cathedrals, and separately dedicated. In England Nonconformist places of worship are commonly called chapels in distinction from those of the established faith to which the term church is applied. In the early history of Massachusetts Bay Colony the Congregational body was the established church, and the first Episcopal church in Boston was consequently termed a chapel, retaining that name, King's Chapel, to the present time.

The word chapel is also applied to an association of union workmen in a printing office for the purpose of promoting and enforcing order among themselves.

Consult "Chapelle," in Viollet-le-Duc, Eugène E., *Dictionnaire raisonné de l'architecture française du XI^e au XVI^e siècle* (Paris 1854-1869); Martin, W. W., *Manual of Ecclesiastical Architecture* (Cincinnati 1897); Bond, Francis, *Westminster Abbey* (London 1909); Dhumez, Hubert, *Chapelles en Provence* (Cannes 1934); Cook, G. H., *Medieval Chantries and Chantry Chapels* (London 1947).

CHAPEL HILL, town, North Carolina, in Orange County; altitude 501 feet; 9 miles southwest of Durham on the Southern Railway. It is the seat of the University of North Carolina (q.v.), established in 1793. The Carolina Playmakers, founded in 1918 by Frederick H. Koch, here annually present plays based on the life and history of the state. Chapel Hill was incorporated in 1851 and has a city manager. Pop. (1950) 9,177.

CHAPEL ROYAL, in the Church of England, a body composed of a dean, a subdean, 36 royal chaplains, 10 canons, a lay choir, and an

organist. The services are performed in an oratory in Saint James's Palace. In Scotland such appointments are purely honorary, carrying with them neither emolument nor any obligation to conduct services.

Consult Sinclair, William, *The Chapels Royal* (London 1912).

CHAPELAIN, shâ-plân', Jean, French poet. one of the earliest members of the Académie Française: b. Paris, Dec. 4, 1595; d. there, Feb. 22, 1674. Having gained a high literary reputation after writing a preface for Giambattista Marini's *Adone*, translating Mateo Alemán's *Guzmán de Alfarache*, and composing four odes, he conceived the project of writing an epic on Joan of Arc, *La Pucelle*, which proved a total failure, although he spent over 20 years on it. The first 12 cantos appeared in 1656; and to so high a pitch had public expectation been wrought that notwithstanding the adverse criticism of Nicolas Boileau and Vincent Voiture, six editions came forth within the following 18 months. Eight new parts appeared in 1757, and the concluding four parts, which were never printed, are in manuscript in the imperial library of Paris. Cardinal Richelieu, to whom he dedicated a poem and whom he assisted in concocting literary works, conferred a pension on him. He presided over the organization of the Académie Française, took a conspicuous part in the early labors of that body, sat as academical critic upon Pierre Corneille's *Le Cid*, and possessed during nearly 40 years a literary prestige, unbroken until his publication of *Pucelle*, although he remained in favor with the court.

Consult Duchesne, Julien, *Les poèmes épiques du XVII^e siècle* (Paris 1780); Guizot, François P. G., *Corneille and His Times* (London 1852); Larroque, Tamizey de, ed., *Lettres*, 2 vols. (Paris 1880-1883); Fabre, L'Abbé, *Les ennemis de Chapelain* (Paris 1888); Bourgoïn, Auguste, *Les maîtres de la critique au XVII^e siècle* (Paris 1889); Fabre, L'Abbé, *Chapelain et nos deux premières Académies* (Paris 1890); Molènes, Emile de, ed., *La Pucelle par Jean Chapelain* (Paris 1891); Searles, Colbert, "The Library of Jean Chapelain," in *Bibliographical Society of America Papers*, vol. 5 (Chicago 1910); Collas, G., *Un poète protecteur des lettres au XVII^e siècle, Jean Chapelain* (Paris 1912); Saintsbury, George E. B., *History of Criticism and Literary Taste in Europe*, vol. 2 (New York 1902-1917).

CHAPELLE, shâ-pêl', Placide Louis, American Roman Catholic prelate: b. Runes, France, Aug. 28, 1842; d. New Orleans, La., Aug. 9, 1905. He studied at the college in Enghien, Belgium, but in 1858 came to the United States and after completing his theological course at St. Mary's Seminary, Baltimore, was ordained priest in 1865, the missions of Montgomery County, Md., being the scene of his first ministerial duties. In 1871 he was made assistant at St. John's Church and afterward rector of St. Joseph's Church, Baltimore, when he was appointed (1882) to the rectorship of St. Matthew's Church, Washington, D.C. On Aug. 21, 1891, he was made coadjutor to the bishop of Santa Fe, N. M.; in 1893 was elevated to the titular archiepiscopal see of Sebaste, and in less than a year succeeded Archbishop Salpointe in the see of Santa Fe. However, he was soon transferred to the diocese of New Orleans in 1897 and in September 1898 Pope Leo XIII appointed him apostolic delegate to Cuba and to Puerto Rico. One year later the Philippine Islands were placed under his care and able direction. Subsequently, he spent three months

in the discharge of his official duties in his country's new possessions. Within eight months he had consecrated four bishops for Cuba and three more for sees in other places. He died in New Orleans of yellow fever.

CHAPERON, shăp'ēr-ōn, a cap or hood. Such a covering, still worn by Knights of the Garter when officially robed, covers the head and neck to the shoulders. During the Middle Ages and the Renaissance it was in general use, but later was appropriated to doctors and licentiates in colleges. Today the word is most often applied to a matron or other mature person who acts as a guide or protector to a young unmarried woman or to a group of young people at social functions.

CHAPIN, chă'pĭn. **Edwin Hubbell**, American clergyman: b. Union Village, N. Y., Dec. 29, 1814; d. New York, Dec. 26, 1880. After studying law for a time he adopted Universalism and was ordained to the ministry in 1838. After 10 years as pastor in Richmond, Va., and Charleston, Mass., he became pastor of the Fourth Universalist Society in New York City. He was an associate editor of *The Christian Leader* in 1872. His congregation grew until it moved to the Church of the Divine Paternity on Fifth Avenue. A preacher of great eloquence and power, he was a founder of the Chapin Home for indigent men and women, and a trustee of Bellevue College and Hospital.

CHAPIN, Francis Stuart, American sociologist: b. Brooklyn, N. Y., Feb. 3, 1888. After studying at the University of Rochester he attended Columbia University, receiving his M.A. in 1910 and his Ph.D. in 1911. Later he became an instructor at Wellesley College and a professor at Smith, where he was also director of the Smith College Training School for Social Work from 1919 to 1921. Then he served as professor and chairman of the department of sociology at the University of Minnesota, 1922-1951; and while there was president of the State Conference of Social Work and president or member of a number of associations concerned with housing, social work, and social science research.

CHAPIN, Roy Dikeman, American automobile manufacturer: b. Lansing, Mich., Feb. 23, 1880; d. Detroit, Feb. 16, 1936. Upon leaving the University of Michigan in 1901 he became associated with the nascent automobile industry, and drove the first motor car to travel from Detroit to New York entirely under its own power. In 1910 he became president of the Hudson Motor Car Company, and in 1917-1918 was chairman of the Highway Transport Commission of the Council of National Defense. In 1932 President Herbert Hoover appointed him secretary of commerce to succeed Robert P. Lamont. He published *The Economics of Highway Transport* in 1921.

CHAPIN SCHOOL, The, is a day school for girls. Opened in New York City in 1901 by Maria Bowen Chapin of Providence, R. I., who died in 1932, it provided eight years of instruction for girls who later completed their training in other schools. In 1907, four years of high school, through the 12th grade, were added, so that graduates of the school should be

eligible for college. It has a regional accreditation. It was incorporated in 1925 as not for profit and since 1928 has occupied a building overlooking the East River at 84th Street.

CHAPLAIN, chăp'lĭn (Fr. *chapelain*). In an early sense a chaplain was a cleric in charge of a chapel. The term was also used to designate the king's secretary or man of affairs, later called chancellor. In France the designation *chapelain* was first applied to the cleric charged with guarding the cape (*chape*) of St. Martin accompanying the armies to the wars, then to priests who said masses in the camps. Later it was applied to priests officiating in chapels of royal palaces. The feudal lords imitated their sovereigns in having chaplains, either personal or family. This custom continued for centuries and was adopted by wealthy commoners. Chaplains are attached as spiritual advisers to religious houses and to individual high ecclesiasts. In some countries, as the United States, chaplains are attached to the armed forces. Some legislative bodies, as the United States House of Representatives, appoint a clergyman as their chaplain.

CHAPLAIN OF THE FLEET, The, a novel by Sir Walter Besant and James Rice, published in 1881. It gives a detailed account of the famous liberties or rules of the old Fleet Prison in London, and of the "Fleet marriages" (q.v.) of the 18th century. The rules applied to houses in certain streets near the Fleet Market, where prisoners for debt were allowed to live, outside the prison, on payment of fees. The book is a storehouse of antiquarian lore about houses, theaters, and the society of George III's reign, and is considered one of the best of those written jointly by Besant and Rice.

CHAPLEAU, shă-plō', **SIR Joseph Adolphe**, Canadian statesman: b. Sainte Thérèse, Quebec, Canada, Nov. 9, 1840; d. Montreal, June 13, 1898. Educated at Masson College, and the seminary at St. Hyacinthe, in 1861 he became a member of the bar, and in 1873 Queen's Counsel. He represented Terrebonne in the Quebec legislature, served as solicitor general, provincial secretary, and (1879-1882) as prime minister of Quebec. He was secretary of state for the Dominion for 10 years (to 1892) and lieutenant governor of Quebec until 1898. He held an LL.D. from Laval University and was knighted in 1896.

CHAPLIN, Charles Spencer, motion-picture actor and producer: b. London, England, April 16, 1889. Both his parents were in the theatrical profession, and his father, Charles Chaplin, Sr., was a well known vaudeville actor. After some schooling in South London, young Charles and his brother Sydney played in vaudeville. In 1910 he went to North America as leading comedian of the Karno Comedy Company, playing the principal vaudeville houses of the United States and Canada, until November 1913, when he joined a motion-picture company at Los Angeles, Calif. Here began his comic portrayal of the pathetic little tramp in baggy trousers and oversize shoes, facing the world in a certain jaunty fashion with his clipped mustache, his cane, and his battered derby. His films came to be recognized as great pantomime

art, and made "Charlie" a familiar figure to millions in all parts of the world. With his clowning was combined a subtle and often biting social satire that not always won him friends.

After appearing in motion pictures for the Keystone, Essanay, and Mutual companies, he built his own studios in Hollywood and formed the Charlie Chaplin Film Company in 1918. He produced such films as *A Dog's Life*, *Shoulder Arms*, *The Kid*, and *The Gold Rush*.

After 1923, as a co-founder with Mary Pickford, Douglas Fairbanks, and D. W. Griffith, of United Artists Corporation, he produced *The Circus*, *City Lights*, *Modern Times*, *The Great Dictator* (in which he first spoke), *Monsieur Verdoux*, and *Limelight*. Accusing him of leftist sympathies, the American Legion attempted to boycott the last film.

Chaplin, who had never relinquished his British citizenship, sailed on Sept. 17, 1952, for a world cruise. Two days later Attorney General James P. McGranery ordered immigration officials to bar his re-entry to the United States until Chaplin had been investigated. Unmoved by this, France made him, in October, an officer of the Legion of Honor. In April 1953, Chaplin surrendered his re-entry permit, refusing to face a hearing on his political views; and, insisting that it was no longer possible for him to work in the United States, he put his home and studios up for sale. In August 1953, he and his fourth wife settled in Geneva, Switzerland.

CHAPLIN, Henry, 1st Viscount CHAPLIN, English politician and sportsman; b. Ryhall Hall, near Stamford, England, Dec. 22, 1840; d. London, May 29, 1923. After studying at Harrow, he went to Christ Church, Oxford, where he formed a friendship with the prince of Wales (afterward Edward VII). Hunting and racing were his primary interests; politics came second. He was master of fox hounds to the Burton Hunt, 1865-1871, 1877-1881, but had to forego his customary daily hunting when he was returned in 1868 to Parliament from Mid-Lincolnshire (a seat he held until 1906), and when he represented Wimbledon from 1907 to 1916. During 1889-1892 and 1895-1900 he served in Lord Salisbury's cabinets, devoting himself mainly to agricultural legislation. In 1916 he was created a viscount. Part of his popularity was undoubtedly due to the fact that his colt Hermit won the 1867 Derby at odds of 66 to 1. He was considered by his contemporaries to be a magnificent example of the sportsman-politician of his day. In 1922 he published *Foxhounds and their Handling in the Field*.

CHAPMAN, Alvan Wentworth, American botanist; b. Southampton, Mass., Sept. 28, 1809; d. Apalachicola, Fla., April 6, 1899. Graduating from Amherst College in 1830, he began his career as a physician, and practiced surgery in Florida, but his hobby was botany, in which he had no academic training. He began sending specimens to the famous Northern botanists Asa Gray and John Torrey, who named a genus *Chapmania* in his honor.

When his Union sympathies during the Civil War caused him some trouble, he gave up his medical practice to devote his time to botany. His *Flora of the Southern States* (1860) made him a leading authority among botanists of the South.

CHAPMAN, Carlton Theodore, American painter and illustrator; b. New London, Ohio, Sept. 18, 1860; d. New York, N. Y., Feb. 12, 1925. His schooling was at Oberlin, Ohio, but he studied art at the National Academy of Design and the Art Students' League in New York City, and at the Académie Jullian in Paris. He specialized in marines and landscapes, and in the Spanish-American War was a war correspondent and artist for *Harper's Weekly*, for which he painted many scenes of naval action.

CHAPMAN, Frank Michler, American ornithologist; b. Englewood, N. J., June 12, 1864; d. New York, N. Y., Nov. 15, 1945. As associate curator, then curator of ornithology in the American Museum of Natural History, New York, from 1888, he originated the presentation of bird groups and seasonal bird exhibits. During explorations in temperate and tropical America he made many excellent close-range photographic studies of bird life. Besides many papers in scientific journals he published *Handbook of Birds of Eastern North America* (1895) and was founder and editor of *Bird-Lore*.

CHAPMAN, George, English poet and dramatist; b. near Hitchin, Herts, England, about 1559; d. London, May 12, 1634. So far as is known, he was educated at Oxford and Cambridge, then went to London, where he became acquainted with Ben Jonson, Edmund Spenser, John Fletcher, Christopher Marlowe, and other writers of the Elizabethan age. His first published work, *The Shadow of Night*, a poem, was brought out in 1594; but it was not until 1598 that his masterpiece, the translation of Homer's works, began to appear. His rendition of the *Iliad* was published in three parts between 1598 and 1609, and the completed version was entered on the Stationers' Register on April 8, 1611. In 1614-1615 appeared his translation of the *Odyssey*, and in 1624 he concluded his translation of the *Hymns*.

Chapman's translations of Homer, though often criticized as inexact and awkward, are virtually original works, and are considered one of the enduring monuments of English literature. It inspired John Keats' sonnet, *On First Looking into Chapman's Homer*, itself a classic. Although the list of Chapman's plays and other works is long, it is for his translations from Homer that he is famed. An edition of his works (in three volumes) was published in 1873-1875, with a critical essay by Algernon Charles Swinburne. A collection of his poems edited by Phyllis Brooks Bartlett appeared in 1941 (New York and London).

CHAPMAN, John (nicknamed JOHNNY APPLESEED), American pioneer; b. Leominster, Mass., Sept. 26, 1775; d. Allen County, Ind., March 1845. A Swedenborgian, he deemed himself called to a mission in the West. He made his way to western Pennsylvania, navigated a boatload of apple seeds and seedlings down the Ohio, landed, planted apples over hundreds of miles of country, and came to be known as "Johnny Appleseed." Wherever he could find listeners, he read Swedenborg to them. Many legends sprang up about him, and he became a folk hero, the subject of poems, paintings, and musical compositions.

In 1812, learning that the Indians were about

to raid the village of Mansfield, Ohio, he made his way through the woods, by night, to Mount Vernon, 36 miles away, and brought troops to defend the town.

In the late 1830's "Johnny" made his way into northern Indiana. He died of pneumonia, and was buried at Fort Wayne.

Consult Himrod, J. L., *Johnny Appleseed* (Chicago 1926); *Johnny Appleseed*, by Harlan Hatcher and others (Paterson, N. J., 1945).

CHAPMAN, John Jay, American lawyer and essayist: b. New York City, Mar. 2, 1862; d. Poughkeepsie, N. Y., Nov. 4, 1933. He was graduated from Harvard in 1884, admitted to the New York bar in 1888, and was in active practice there until 1898. His essays and speeches attracted considerable attention because of their striking individuality and original point of view. His works include *Emerson, and Other Essays* (1898); *Causes and Consequences* (1898); *The Maid's Forgiveness*, a play (1908); *A Sausage from Bologna*, a play (1909); *Learning, and Other Essays* (1910); *The Treason and Death of Benedict Arnold*, a play (1910); *William Lloyd Garrison* (1913); *Notes on Religion* (1915); *The Greek Genius* (1915); *A Glance Toward Shakespeare* (1922); *Letters and Religion* (1924); *Dante* (1927); *John Jay Chapman and His Letters*, ed. by M. A. DeW. Howe (Boston 1937).

CHAPMAN, Maria Weston, American reformer: b. Weymouth, Mass., July 25, 1806; d. there, July 12, 1885. She received her education at Weymouth and in England. In 1829-1830 she was principal of the Young Ladies' High School, Boston. She married in 1830; became an active opponent of slavery in 1834; and after the death of her husband in 1842, went to Paris, France, and assisted the anti-slavery cause with her pen, returning to America in 1856. She wrote *Right and Wrong in Massachusetts* (1839); *Right and Wrong in Boston: Report of the Boston Female Anti-Slavery Society*, 5 vols. (1836-1840); and compiled the anti-slavery hymnbook, *Songs of the Free, and Hymns of Christian Freedom* (1836). In 1877 she edited the two-volume autobiography of her friend, Harriet Martineau.

CHAPMAN, Oscar Littleton, American public official: b. Omega, Va., Oct. 22, 1896. Educated at the universities of Denver and New Mexico, he was assistant chief probation officer of the Juvenile Court, Denver, 1922-1924; chief, 1924-1927. He graduated from Westminster Law School, Denver, and was admitted to the bar in 1929. Appointed assistant secretary of the interior in May 1933, he became under secretary in 1946, secretary in 1949, resigning in January 1953 with the change of administration.

CHAPMAN'S HOMER. George Chapman (1559-1634), writer of plays and contemporary of Spenser, Marlowe, Jonson and Shakespeare, was a great translator in the great age of translations that brought forth the English Bible and so many versions and adaptations of the ancient classics. He published seven books of the *Iliad* in 1598, and by 1616 had published together the *Iliad* and the *Odyssey* complete in rhymed 14 syllable verse. The literature of his own time contains much complimentary allusion to him, and the

esteem of later generations is manifest in many glowing tributes from eminent literary characters, probably the most familiar and the most stimulating being Keat's sonnet, "Much have I travelled in the realms of gold":

"Oft of one wide expanse had I been told
That deep-browed Homer ruled as his demesne;
Yet did I never breathe its pure serene
Till I heard Chapman speak out loud and bold...."

The "loud and bold" of Keats contains or suggests the qualities that have made Chapman's translation live in spite of the lack of polish, of exactness, and sometimes of dignity, that are charged against it. Pope, his later rival, says "he covers his defects by a daring fiery spirit that animates his translation." Even Matthew Arnold, the severe critic of all translations of Homer, who declares that "in a verse translation no original work is any longer recognizable," characterizes Chapman as "plain spoken, fresh, vigorous, and, to a certain degree, rapid." Arnold, however, condemns him on the whole. "Homer," he says, "is rapid in his movement. Homer is plain in his words and style, Homer is simple in his ideas, Homer is noble in his manner . . . Chapman renders him ill because he is fantastic in his ideas. . . . His conceits are un-Homeric, and his rhyme is un-Homeric; his manner and movement are un-Homeric; his diction . . . often offends . . . by wanting Homeric nobleness." He condemns him most of all because "he cannot forbear to interpose a play of thought between his object and its expression. Chapman translates his object into Elizabethan, as Pope translates it into the Augustan of Queen Anne; both convey it to us through a medium." "For the Elizabethan age," write Butcher and Lang in the preface to their translation of the *Odyssey*, "Chapman supplied what was then necessary, and the mannerisms that were then deemed of the essence of poetry, namely, daring and luxurious conceits . . . Without Chapman's conceits, Homer's poems would hardly have been what the Elizabethans took for poetry; without Pope's smoothness, and Pope's points, the *Iliad* and the *Odyssey* would have seemed tame, rude, and harsh in the age of Anne." If, as Arnold reasonably insists, the real test of successful translation is the attempt to satisfy the scholar who has also poetical feeling, Chapman must be said to please most those not perfectly possessed of the means of really judging him as a translator, but who come to his work more or less as to an original poem in the Elizabethan manner. Such readers will find him admirable for what R. H. Horne calls "his commanding energies, fullness of faith in his author's genius, and in his own inspired sympathies, his primitive power, and rough truthfulness of description"; and will feel not only the inspiration of the Homeric narrative but the inspiration of the translator himself.

GRANT SHOWERMAN.

CHAPPE, shăp. **Claude**, French abbé and inventor: b. Brûlon (Sarthe), 1763; d. Paris, Jan. 23, 1805. Having invented an ingenious system of signals to communicate at a distance with his friends, he presented it to the French Legislative Assembly in 1792. It was successfully tried between Paris and Lille, on a length of 48 leagues, and was adopted by the government. Chappe established several lines in France, and the one running north was first put in motion

to announce the recapture of the town of Condé from the Prussians. The inventor was at once rewarded by the convention, which, by a decree, appointed him *ingénieur télégraphe*. The lines were extended all over France, and the system was also adopted, with some alterations, through Germany and England. The attacks to which he was subjected, by persons jealous of his invention, preyed so much upon his mind that he committed suicide. His semaphore consisted of an upright post, with a transverse bar at top, and with two smaller arms movable on pivots. The position of the bars represented letters or words, and the posts were placed within visible distance one of another. Messages were conveyed a distance of 150 miles in 15 minutes by this method. Consult *Histoire de la Télégraphie* (1824) by Ignace Urbain Jean Chappe, brother of Claude Chappe.

CHAPPE D'AUTEROCHE, shâp dô-trôsh', Jean, French astronomer: b. Mauriac, Auvergne, March 2, 1722; d. San José, Calif. Aug. 1, 1769. He was a priest, but giving his whole attention to astronomy, became one of the assistants of Cassini in delineating the general map of France, and edited the astronomical tables of Halley. In 1760 he was designated by the academy to make an observation of the transit of Venus over the sun's disc, which Halley announced would happen June 6, 1761. He consequently set out for Tobolsk, in Siberia, which was pointed out as the most favorable point of observation. His mission was successfully accomplished; and returning to France at the end of two years, he published in 1768 his *Voyage en Sibirie*. The following year he sailed for California to observe another transit of Venus, which was to take place June 3. He was equally successful on this occasion, but died soon afterward. The results of his last expedition were published by Cassini, under the title of *Voyage de la Californie* (Paris 1772).

CHAPPED HANDS, a form of eczema (*eczema fissum*), caused by exposure to extremes of cold and heat. The skin swells and cracks and there is itching, pain and heat and in severe cases ulceration. The lesions are generally treated with oxide of zinc ointment, or a solution of borax in glycerin and rose water or with glycerin alone. The hands should be protected by warm gloves. Chapping may be avoided to a great extent by washing the hands with a bland soap in tepid water and thoroughly drying them afterward.

CHAPPELL, chăp'él, William, English musical antiquary: b. London, Nov. 20, 1809; d. there, Aug. 20, 1888. For the most of his life he lived in London, where he was for some years a member of a great music publishing house. His works of importance include: *Collection of National English Airs* (1838-1840); and *Popular Music of the Olden Time* (1855-1859). He took a principal part in the foundation in 1840 of the Percy Society and the Musical Antiquarian Society, and published the first volume of *History of Music* in 1874.

CHAPPLE, Joe Mitchell, American journalist: b. La Porte City, Iowa, July 18, 1867; d. Miami, Fla., April 17, 1950. He studied at Cornell College, Iowa, and was engaged

in journalism in Dakota, Ashland, Wisconsin, and Chicago until 1897, when he became editor and publisher of *The Bostonian*, later changed to *The National Magazine*, Boston, Mass. His writings include *The Minor Chord* (1895); *Heart Throbs* (1906); *The Panama Canal* (1907); *The Happy Habit* (1908); *Heart Songs* (1909); *History Making* (1911); *Heart Letters* (1912); *Heart Chord* (1915); *Harding, the Man* (1923); *Vivid Spain* (1927); *Our Jim* (1929); *Face to Face With Our President* (1930); *Chapel Bells* (1934); *Mother O'Mine* (1935); *Willkie and American Unity* (1940). He produced a series of motion pictures and had a nationwide radio program (1945).

CHAPTAL, shâp-tâl, Jean Antoine Claude, COMTE DE CHANTELOUP, French chemist and statesman: b. Nogaret, Lozère, June 4, 1756; d. Paris, July 30, 1832. During his medical studies and practice he devoted much research to the science of chemistry, in which he soon became eminent, and was appointed professor at Montpellier, where he taught successfully the doctrines of Black, Lavoisier and Cavendish. He established chemical works near Montpellier, the first attempted of the kind, by which he was soon enabled to produce various chemicals hitherto imported, such as the mineral acids, alum, soda and salts of lead. The authorities of Languedoc heaped honors on him; the Spanish government offered him a pension of 56,000 francs to go to Spain, and according to his biographer, Washington wrote three times to Chaptal, inviting him to America. After the outbreak of the French Revolution he published a political pamphlet, entitled *Dialogue Between a Montagnard and a Girondist*, and was arrested, but through the intercession of friends was liberated. The committee of public safety placed him in charge of the powder mills of Grenelle, now a part of Paris, which produced, under his management, 3,500 pounds of gunpowder daily. Once more returning to Montpellier, he was elected member of the Institute, and devoted himself to science, until Bonaparte summoned him to the council of state, where he had the supervision of national education. When Lucien Bonaparte resigned the portfolio of the interior, Chaptal took his place as minister, and for four years performed the duties of the department with much administrative ability. He founded the conservatory, school of arts, chambers of commerce and society for encouragement of industry, introduced the modern French system of weights and measures, established a model farm and a system of distribution of agricultural seeds, reorganized the prisons and hospitals, extended the network of highways over the face of the country and organized the carrying out of the plans of extension of the Louvre and rues de Rivoli and Castiglione, since completed by Napoleon III. On Napoleon's return from Elba, the count was appointed director-general of commerce and manufactures and minister of state. Louis XVIII struck him from the list of peers, but left him on the roll of the academy. His works are all on chemical subjects, and may yet be consulted with advantage.

CHAPTER (Latin *caput*, head), one of the chief divisions of a book. As the rules and statutes of ecclesiastical establishments were arranged in chapters, so also the assembly of

the members of a religious order, and of canons, was called a chapter, because some or all of the chapters containing the rules were read there; and the place where they assembled, as well as the reproof administered to a delinquent member, by reading the chapter rules, which he had transgressed, had the same name. The knightly orders, which originally had much of the ecclesiastical constitution, used this expression for the meetings of their members, and even some corporations of mechanics or tradesmen called their assemblies chapters. In England, as elsewhere, the deans and chapters had the right to choose the bishop, but Henry VIII (r. 1509–1547) assumed this right as a prerogative of the crown. In the United States, the local branches of national Greek-letter societies are called chapters of the society.

CHAPTER HOUSE, a building attached to a cathedral, collegiate church, or church belonging to a religious house, in which the chapter meets for the transaction of business. Chapter houses are of different forms, sometimes regular polygons of 4, 8, or 10 sides, and in other cases circles or parallelograms; and their architecture is often noteworthy.

Continental chapter houses are always rectangular in shape. Among the most notable of English chapter houses are those at Lincoln Cathedral, which is decagonal, with vaulting springing from a central column; Salisbury Cathedral, octagonal, with fine sculptures; Wells Cathedral, octagonal, the finest Decorated chapter house in England; Southwell Minster, octagonal, with a beautiful roof unsupported by a central pillar, and with fine early carving; York Minster, octagonal, an example of Decorated work of great beauty, Worcester Cathedral, circular, with a single shaft.

Bristol Cathedral has a chapter house of the Norman period, in shape a parallelogram. The chapter houses at Gloucester and Canterbury cathedrals are also parallelograms: Gloucester, Norman (restored), with Perpendicular east bay; the lower part of Canterbury's chapter house completed during the first part of the Perpendicular period (late 14th to mid-16th centuries).

CHAPULTEPEC, chā-pōōl-tā-pēk' (meaning Grasshopper Hill), a rocky hill about 200 feet high and three miles southwest of Mexico City. The early Aztecs, who took it from the native Indians, built aqueducts here to supply their capital with water; Aztec emperors used the hill as a pleasure ground. Sharply precipitous on the northern, eastern, and part of the southern sides, it slopes gradually on the west and southwest to level marshy ground partly covered with a cypress grove. In 1783 the Spanish began to build a castle on the summit for their viceroys' summer residence, but abandoned construction after four years. In 1840 work was resumed and in 1842 a military academy was installed in it. Just before the Mexican War (1846) the castle was fortified to command the main road into Mexico City from the southwest. After its capture in 1847, Gen. Winfield Scott used the castle as temporary headquarters.

In 1864 the fortress became the imperial castle of Emperor Maximilian and Empress Carlota, who thought the view from the hill one of the most beautiful in the world, surpassing even that of Naples. The castle was renovated for them in

European style, with gilt furniture, damask and French tapestries, glittering chandeliers, statuary, and marble urns. There they received and entertained the refugee Confederate generals, whom they encouraged to settle in Mexico after the Civil War.

During the republic President Porfirio Díaz used it as a residence until he was exiled in 1911. Under President Lázaro Cárdenas in 1937, the hill was made into a public park and the castle became a museum. In 1945 it was the scene of the Inter-American Conference on Problems of War and Peace, which formulated the Act of Chapultepec. A new residential section, Chapultepec Heights, now adjoins the hill on the northwest. See also **PACTS AND CONFERENCES: WORLD WAR II.—Act of Chapultepec.**

BATTLE OF CHAPULTEPEC

After the victory of Molino del Rey (q.v.) in the Mexican War, United States troops prepared for the assault on Chapultepec on Sept. 12–13, 1847. The Mexican general, Nicolás Bravo, commanded a garrison of 800, including 40 students of the military academy. Along its approaches were some 4,000 to 4,500 more troops but Gen. Antonio López de Santa Anna dared not strip the other entrances to Mexico City. The hill was guarded by strong batteries, and protected by walls (an aqueduct on the north) which shielded other batteries; through the marshy fields in front of these were irrigating ditches, some large and deep, with high banks and sticky bottoms, very serious obstacles to troops and artillery.

On the 8th, Gen. Winfield Scott had captured a set of long stone buildings southwest of Chapultepec and forming some protection for artillery, though under the castle's guns. Scott's troops numbered 7,500.
